Souvenir de la Malmaison Rose.—Mr. D. T. Fish inquires (p. 10) why this Rose is malformed early in the year, and improves as the season advances, and asks whether the improvement can be the consequence of an excess of vital force early in the year. I think he will find that it is more likely due to a deficiency of vital force at that period. There may be a plethora of food and yet imperfect assimilation. To produce the coloured corolla requires the greatest concentration of vital force of which a plant is capable. Probably this Rose requires for its perfect development a higher and more constant temperature than the early summer affords. On this subject see the "Quarterly Journal of Science" for October, 1878; article, "What is a Flower?"—F. T. MORR, *Birstall Hill, Leicester.*

Rose The Bon Silene.—This was sent to me about 1836 by M. Vibert, of Longueumeux, near Paris. It is the forcing Rose, *par excellence*, of all others to date. It has fine long, large, buds of a dark rosy-red, opening to a delicate pink, with a delicious odour, and not fully double. Cut when one-third grown and opened in a cool temperature it surpasses all others, having a fine footstalk and rich foliage. There are tens of thousands cut every day for our bouquet makers. Boston growers have entered into it so largely that the Rose passes under the cognomen of Boston Bud.—"Gardeners' Chronicle."

The Atlantic forest, according to Professor Gray, is composed of 66 genera and 155 species; the Pacific forest has only 31 genera and 78 species of timber trees.

PLATE CXXXI.

VERBENAS.

(WITH COLOURED FIGURES OF FOUR NEW KINDS.)

Drawn by Mrs. DUFFIELD.

VERBENAS have long been favourites because of the many uses to which they may be put. In many parts of the country, especially in the west of England, Verbenas rank high as exhibition plants; they are shown in the form of specimens in pots, and also in a cut state, much in the way in which Roses are shown. They are subjects cultivated with comparative ease; out-of-doors they bloom profusely, and stand well till quite late in the autumn; and if the lustre of the flowers happen to become dimmed by a storm, a burst of sunshine quickly restores their lost beauty. As to where and by what successive steps Verbenas have become improved, it is not necessary to allude. As in the case of other flowers, their present fine development is, doubtless, the result of years of patient industry. From the Continent have come many fine varieties, and we have also some excellent kinds the produce of English-saved seed.

For flower garden decoration, a few of the best will be found to be Celestial Blue, Crimson King, Edwin Day, cerise; Firefly, vivid scarlet; James Birbeck, shaded pink; La Grande Boule de Neige, pure white; Mrs. Mole, lavender; Oxonian, purple, with a white eye; Purple King; Wonderful, plum-coloured; and two new varieties, viz., Gruss aus Erfurt, bright scarlet, and Mdlle. Emilie Hulter, bright purple, with a white eye. A pretty and effective bed may be secured by mixing a few good varieties together.

The varieties figured in the accompanying illustration are: Annie Improved, one of the best of the few striped varieties in cultivation; Lady of Lorne, bluish white, with a rosy-purple eye, a very fine exhibition variety; and two remarkably good new varieties in the possession of Mr. Cannell, of Swanley Kent, named Henry Cannell, crimson-scarlet, a fine and effective hue of colour, and Swanley Gem, white, suffused on the edges with mauve-blue.

In the west of England, at such exhibitions as Trowbridge, Shepton Mallet, Sherborne, Bath, &c., Verbenas in pots are shown in such fine character as to astonish those not in the habit of seeing the Verbena grown as an exhibition plant. The specimens, which are cultivated in large pots and of considerable size, are laden with a profusion of good trusses of bloom, the produce of one season, from cuttings struck in March. When well rooted they are potted into small pots, and are afterwards repotted into two sizes larger; when these are filled with roots they are shifted into their blooming pots, often from 8 in. to 10 in. in diameter. The leading shoots are stopped two or three times in order to produce six or eight strong shoots, and, as the trusses of buds appear, all are removed except the terminal buds, as they rarely, if ever, produce fine pips.

To insure a good head and succession of bloom, a strong growth is encouraged, especially shoots from the base of the leading flower stem, as they are found to produce trusses equal in beauty to those of the leading shoots. During wet weather the plants are placed under glass to protect them from harm in that direction, and when the flowers are expanding they need to be protected from the sun. The best soil is loam, leaf mould, and peat in equal proportions, with a sprinkling of guano thrown among it. This gives a free, light, open soil, and the pots should be well drained.

When grown out-of-doors the Verbena should have liberal treatment; a dry, open border should be selected for it, and the ground should be trenched and well dressed with spent hotted manure and leaf soil. Under such circumstances the plants can be put out about the end of May, and as they make growth the shoots require to be pegged securely over the bed and be kept well thinned. If good blooms be wanted for exhibition in a cut state, it is necessary, as the show draws near, to place lights from a frame on the beds as a protection from heavy rains; indeed, it is impossible to have fine, clean trusses for show purposes without some such protection. Some of the finest exhibition Verbenas will be found to be Beauty of Coleshill,

Annie Improved, Angusto Buckner, Crystal Palace, Duke of Edinburgh, Her Majesty, Holfgartner, Kindermann, Lady of Lorne, Mauve Queen, Pre-eminent, Reine des Roses, Star of Erin, and Warrior.

When Verbenas are exhibited as cut blooms, which they were often last year by Mr. Cannell, some five trusses or so are put into a bunch, and a stand of flowers, well set up, is a charming feature at an exhibition. Some are sweetly fragrant, a property which gives them additional value. D.

GARDENING FOR THE WEEK.

Flower Garden.

Auriculas.—These now require daily attention, and if it be intended to exhibit any plants of them, steps should be taken to forward those that are too late, and to retard those likely to be over before the show day. In this, as in most other things, those who are attentive to trifles, and who manage their plants themselves, will have a great advantage over growers who think that such work can be well carried out by others. It may not be generally known that there is quite a month, on an average, between the flowering of the earliest and latest varieties of Auriculas. Taylor's Glory and Campbell's Pizarro, for instance, are always very early, and, in order to have them in flower with the general collection, they ought to be placed in a lean-to frame or house with a north aspect. On the other hand, Smiling Beauty, Lancashire Hero, Earl Grosvenor, Duke of Argyll, Beeston's Apollo, and a few others are always late, and must be pushed forward. The Auricula is easily forced, but it must be done in one particular way; the plants must be close to the glass, air must be admitted freely by day, and the ventilators should also be open a little at night.

Carnations and Picotees.—Since these were potted, they are making good growth, and care should be taken to water only when they require it; indeed, it would be better rather to under water than overdo it. Mr. Dodwell, who has had a lifetime's experience in the culture of these plants, does not give any water until nearly the middle of April. He tells me that he potted and placed his plants out-of-doors in February, merely using the shelter alluded to last week (p. 207). Mr. Dodwell has also an excellent plan for preventing the soil from becoming hard through heavy rains, and that is by placing oyster shells on the surface, with the hollow side down. Now that fine weather has set in, and the barometer points to a continuance of it, it will be necessary, where the plants are put out in beds, to stir the surface soil, taking care that the plants are made firm and supported by a stick if required. Where old plants in borders were not layered in autumn, that had better be done now, but the plants should be allowed to flower this season without removal.

Tree Carnations.—Amongst the many plants that have come recently into more general use for winter flowering, these sweet-scented, continuous-blooming subjects hold a prominent position, and deservedly so, as, for the purpose required, they have few equals. They differ from most plants in not producing a sheet of flowers at once, and in this way sometimes furnishing more than are required. On the contrary, they keep opening in succession over a long period, and in a manner that admits of every individual bloom being used. Cuttings made now from young shoots furnished by plants that have been forced, and put in a medium temperature, will root freely, and make useful stock for next winter.

Dahlias.—It is still very cold at night, even in rather favored districts; the thermometer here last Saturday registered 7° of frost—a warning that we should be very careful how we expose our plants at night; they would certainly have suffered in a cold frame if the glass were not well covered. If the plants be still in a heated house they certainly ought to be placed quite close to the glass, and be furnished with sufficient air. If stock enough be not yet obtained no time should be lost in starting such sorts as are wanted.

Pansies and Pinks in Beds.—Many Pansies that seemed hopelessly lost are now starting from under the surface of the ground, and in this way we hope to save most of our varieties. Keeping the surface soil stirred is of much benefit to the plants; it is certainly desirable to have a reserve in pots or boxes, and to keep them in cold frames, to make good any that happen to die off in winter. Pinks in beds are much the same as Pansies as regards treatment. Mr. Ball, of Slough, recommends planting them out in spring. If this be done, they must be grown in pots and kept under glass, like Carnations and Picotees, during winter.

Phloxes in Pots.—I have already stated how useful these are for conservatory and greenhouse decoration in the autumn. Plants of them propagated last year, and that are now in 5-in. pots, if shifted

into 9-in. and 10-in. ones make noble specimens, each with five or six spikes, which are sufficient to produce a good display. The Phlox, whether it is grown in pots or planted out, is a gross feeder. It requires rich soil and manure water in abundance when the plants are in active growth.

Polyanthuses.—These are now coming into flower very freely. William the IV., Napoleon, Formosa, and Alexander (Pearson's), opened in the order in which their names stand. The two last named are fine varieties, Alexander especially so; it is an old variety and very scarce. It is a good time now to sow seeds of Polyanthuses either in a cold frame or where the frame has been placed over a manure bed, the heat of which is nearly gone. Plants produced from this sowing flower very strongly next year. Do not at any time coddle the plants in heat, as this is injurious to them.—J. DOUGLAS, *Loxford Hall, Ilford.*

Shrub Planting and Renovating Lawns.—These are operations which should be completed as early as possible in order that root action may have commenced before a period of drought has set in. It is also desirable to roll all lawns well, whilst, as yet, there is moisture sufficient to render them capable of being thoroughly consolidated. It is simply labour in vain to roll lawns when dry; Mossy, or patchy places may be renovated by raking the affected spots deeply and sowing them with Grass seeds, which should be covered with fine soil and well firmed. In order to maintain a good green sward, no dressing that can be applied is so effective as wood ashes and soot mixed in about equal proportions, and strewn over the ground in showery weather. Where new lawns are to be formed by sowing Grass seeds, the sooner now they can be got in the better. The first requisite is that the ground should be well drained, the next that it should be thoroughly consolidated and have a smooth, dry surface. If it be at all wet or dauby, defer sowing till it is dry, as it is only then that the seeds can be raked and rolled in, without which it is unreasonable to expect a good lawn.

Roses.—A month ago Roses seemed to be severely injured, but the last few mild days have caused them to bud forth, and after taking a general survey, we do not find that more than two per cent have succumbed. All of them are now pushing so fast that it will be desirable to prune them immediately, after which, lightly fork in the manure that was applied as a mulching in the autumn, and if more manure can be spared, re-mulch, for Roses are not easily overdone in the matter of manure. Any that have yet to be planted should receive immediate attention.

Spring Flowers.—Already, after such protracted cold, many hardy flowers are in full beauty; indeed, spring flowers generally are growing rapidly, and, by way of setting them off to advantage, let every nook and corner be kept neat and clean. All vacant beds and borders should be put in order for their summer occupants, each being prepared according to the plant or plants intended for it. Calceolarias, Violas, Verbenas, and all sub-tropical plants cannot well have too much manure trothed into them, but Pelargoniums and most other bedding plants flower best when given but little. All the beds, however, require to be deeply dug. By way of increasing the space for bedding plants in houses, such as Golden Feather Pyrethrum and Tagetes signata pumila, can be raised in the open air. Sow at once on a south border, and if any old lights or hand-glasses can be used, well and good, but such are not really necessary; we sow thinly on light vegetable mould, cover the seeds with the same, and transplant direct to the flower beds as wanted, thus virtually doing away with pots, boxes, indoor space, and a great amount of labour.

Asters, Stocks, Zinnias, and Helichrysums.—These should now be sown in frames, and as soon as germination has taken place, they should be quite exposed to the atmosphere when the weather is at all favourable; when large enough to handle, prick them out into similar frames, and keep them close till they have become established; afterwards, gradually inure them to full exposure. Many kinds of annuals for early summer flowering may now be sown in the open ground, such as Mignonette, Clarkias, Collinsias, Eschscholtzia, Honesty, Larkspurs, Nemophilas, Sweet Peas, Saponarias, Scabianthus, and Virginian Stocks, all of which are cheap, easily raised, very showy, and lasting.—W. W.

Indoor Fruit Department.

Vines.—The remarks made (p. 185) with regard to late Vines are still applicable. All such Vineries should be put in working order forthwith. The few sunny days which we have had has already caused some of the more vigorous Vines to bleed, and our remedy for that is, as soon as it is observed, to start the Vines into active growth by closing the house, and maintaining a humid minimum temperature of 60°. This soon has the desired effect, as the sap is then diverted into its proper channel. At length forcing has become an

easy operation, the last few days' sun having worked wonders both as regards appearance and progress of early Vines; the attempt may therefore now be made to overtake lost time by closing up very early, and allowing the temperature to run up to 90° for an hour or two in the afternoon, taking care that there is plenty of air-moisture at the time of closing. Keep the thinning of bunches well in hand by commencing to thin as soon as the first bunch is ready. No other work should be allowed to interfere with or delay this, as the sooner all surplus bunches and berries are removed, so much the better will the general crop be. Train, tie, and stop the shoots in something like methodical order. As regards training and tying, get the side shoots in a horizontal line if you can without breaking them, but if this cannot be done, what does it matter if they are not quite straight? the fruit will be equally good. A far more important point is seeing that no more shoots are retained or tied in than can have full exposure to the light, and this latter must govern the stopping of the shoots. If there be space for the growth, let them remain, but if not, and they are likely to get crowded, then frequent pinchings will be necessary. Successional houses will require disbudding as soon as it can be perceived which are likely to make the best shoots and produce the finest bunches, and one shoot to each spur is generally ample in the case of young vigorous-growing Vines, but old Vines may generally have two growths. Though Vines may be planted at almost any time, with fair prospect of success, the best season is from now to the middle of April. Every one now knows, or ought to know, considering all that has been written, how to make a Vine border, and, this being ready, secure strong one-year-old Vines, and cut them back to a couple or three joints. As soon as these have begun to push afresh shake them out, remove every particle of soil, and replant them, spreading the roots out level, and covering with about 6 in. of soil. Then thickly mulch with stable litter, whether the borders are indoors or out; if the latter, no water will be required, and the Vines, in such cases, should also be left sufficiently long to admit of the old stems having their tops put through the wall in order that the new growth may start from the inside. If the borders are inside, water as soon as planted with warm water, but do not turn on much top heat till new root action has commenced.

Pines.—With increased solar heat a brisker bottom heat may now be maintained for plants in all stages of growth, and there should be a like increase of atmospheric moisture, except in the case of those that are in blossom; more water will also be requisite. All the stock should now be closely examined as to their requirements in this respect at least once weekly, and a weak solution of guano water may now advantageously be given to all plants, except suckers that were last potted. These should be kept moist by a confined atmosphere and occasional syringings, and the application of some slight shading till the roots are seen at the sides of the pots. Do not delay the potting of any that have been wintered in small pots, for if once they get pot-bound, the check invariably results in premature and useless fruit. All recently shifted plants should, when the sun is at all powerful, be shaded for a couple of hours each day, till the roots have extended into the new soil, when it may be discontinued, except in the case of smooth Cayennes, which do best when constantly screened from the scorching midday sun.

Peaches and Nectarines.—Continue to disbud and tie in the shoots in early houses and thin the fruit with a free hand; usually this operation is done but sparingly, till stoning is over, as so many fruits drop during that process; but the very fact of their falling should act as an incentive to thin at once. It is the strain that has been, and still is, on the trees that causes the fruit to drop, whereas, if the energies wasted in carrying an over-crop were given the chance of expending their force on just the quantity of fruit intended to ripen, there would not only be no falling at stoning time but the fruit would be in every way finer, and the uncertainty of a crop ever failing would be reduced to a minimum. Guard against the borders getting dry; so much fire heat has been very drying, and though such drought may not be very deep, still, as surface-feeding roots are of immense import, encourage them by watering with warm water, and to give off that ammoniacal vapour which is so fatal to red spider. On frosty mornings delay syringing till the sun has absorbed the condensed moisture of the previous night, but syringe freely at all other times, not only to keep at bay insect pests, but because the trees revel in abundance of moisture, so long as the air is changed daily so as to prevent stagnancy. The trees in succession houses that may be in flower during such bright weather as we are now having will need no artificial fertilisation other than an occasional shaking of the trellis. Bees, too, will now find their way to them, and aid materially in effecting a good set. Keep late houses open night and day, to retard and prevent them from getting much in advance of the trees on the open walls, in order that a continuous succession of fruit may be kept up till the open-air crops are ready.

Figs.—Beyond the importance of giving these—especially old, free-bearing trees—plenty of water, and the richest top-dressings, there is, for the present, little to add, other than that stopping the shoots by pinching will now require frequent attention, and this should be done, a few points at a time, at intervals of a few days, or even a week—a plan by which a longer succession of fruit is insured. The surface roots of Fig trees are the mainstay of the fruit, and hence the importance of top-dressing and constantly feeding with manure water. As to any that are bearing freely in pots, liberal treatment must be continued till there are indications of the fruit approaching maturity, when a drier—not dry—state, both of root-run and atmosphere, should prevail.

Strawberries.—We gathered our first fruit on the 6th—a month later than usual this year, though the plants were treated in all respects as in previous seasons, thus showing the effects of the protracted winter. Now that spring has become so far advanced, there are but three requisites necessary in order to obtain good Strawberries till the open air fruits are in. The first is, to have plenty of good plants; the second is, convenience for growing them; and the third is, never-failing attention to their wants. It is presumed that the two first are established, or the third will be impossible. I know no fruit forcing so exacting as Strawberries, for once neglect watering or airing at the proper time, and fine fruit need not be expected. With sunny weather water will be required twice a day, or, if not, they should at least be looked over with that intent. In fine weather bees will aid the setting process, but, should a dull period set in, still use the camel's-hair brush. Crops ripening should have all the air possible; but do not attempt to roast them into flavor by withholding water from the roots—a mistake too frequently made, and which is a sure precursor of red spider.

Melons.—These are now growing rapidly, and those to be trained on trellises in houses should have the side shoots pinched till they reach the trellis, but those in frames should be allowed to retain their side shoots, and the main points should be pinched out as soon as they attain 18 in. or 20 in. in length. Keep the linings well renewed, so as to maintain a minimum temperature of 65°. Probably no water will be required till after the fruit is set, but it will be well to occasionally examine the soil in order to prevent its becoming anything like dust dry. In houses where the air is more light and drying the plants should be syringed at least once a day, and this will be almost all the water they will require till the sun has acquired greater power. Now that daylight and sunshine are in the ascendant, increase both the atmospheric moisture and the temperature; the latter may range by night at from 65° to 70°, and by day from 70° to 80°.—W. W.

Extracts from my Diary, March 17 to 22.

FRUIT.—Shifting Strawberries from 6-in. pots into 8-in. ones. Thinning Grapes. Shifting Figs out of Pine stove into Peach house. Potting another batch of Strawberries into Pine stoves. Shifting pot Vines out of Vinery into Pine stove. Top-dressing Strawberries for forcing. Watering late Peach houses. Pruning and nailing Plums. Hoeing and cleaning among Gooseberry trees. Tying Peaches in early house. Thinning flower buds of Cherries in cold houses. Tying and stopping Vines. Tying Fig trees. Wheeling long manure among Currant trees as mulching. **FLOWERS.**—Boxing Pelargoniums for summer bedding out of cutting pots. Shifting seedling Calceolae into 6-in. pots. Potting in cuttings of Verbenas. Sowing Cockscombs and Foxgloves. **VEGETABLES.**—Sowing the following kinds of Peas, viz., G. F. Wilson, Osman Pacha, Marvel, and Standard. Planting another batch of Cucumbers in Pine stove. Cultivating ground between Cabbages. Sowing Osborn's French Beans in 4-in. pots. Planting International Kidney and Myatt's Prolific Potatoes in frames for exhibition purposes. Pricking out Cauliflowers into frames out of seed boxes. Potting Tomatoes. Tying Cucumbers and sowing more seed. Drilling ground for Potatoes. Preparing border for Parsley by dressing it with ashes from the rubbish heap.—R. GILBERT, Burghley.

Ants and Paraffin.—I have lately been troubled very much with ants amongst pot Roses which were fast coming into bloom. I found several of the bloom buds eaten partly away, and a closer examination revealed the fact that the depredators were ants. I watched them through a microscope and saw them plainly doing the mischief. I at once procured a large watering pot full of water, with just enough paraffin added to taint the water; this was sprinkled through a fine rose over the heads of the plants. The ants at once took to flight and not one has since reappeared. This may prove a hint worth remembering, especially by those who are in any way troubled with these little pests.—H. HARRIS.

TREES, SHRUBS & WOODLANDS.

CUTTING DOWN ARBUTUS HEDGES.

"E. F." (p. 211) does not say what the species of *Arbutus* is of which the hedge described as twenty years old and now too high is composed, but I have little hesitation in saying that it may be cut down with safety, as *Arbutus*es are plants that generally break freely, and afterwards make vigorous growth. Some of the strong-growing species, such as *A. Andrachne*, that had attained a large size, and were killed in the winter of 1860-61 down to the surface of the snow, which then covered the ground, broke from the crowns in the spring, and have now formed fresh stems 8 in. or 9 in. in diameter, with heads proportionately large, and without close examination it would not be noticed that they ever had been injured in any way. I should recommend the hedge to be at once cut down to within 12 in. of the ground, using a saw for the operation, not a bill-hook, which will split and hagle the stumps. Do not cut these, or anything else that is intended to grow up again, and is exposed in the open air, straight off in a horizontal line, particularly when the wood has grown to a considerable thickness, but slanting, say at an angle of 50°, so that the water will not lodge on the surface of the cut. By doing the work immediately, the latent buds on the stumps will have time to gradually develop, and be in a state to push shoots in good time, so that they may get fully matured before autumn. The young growth will most likely be of a character to require shortening back somewhat twelvemonths hence, or it will rush straight up then without breaking, so as to have sufficient bottom.

T. BAINES.

— *Arbutus*es, if cut down now, will break as freely as common Laurels. Use a bill-hook in preference to a saw for the purpose, and do not cut them lower than 2 ft. from the ground.—W. H.

— Let me tell "E. F." (p. 211) that we have many *Arbutus* trees here which are constantly becoming too large for their places, and we cut some of them down nearly every winter to generally about 3 ft. from the ground, and they never fail to start freely and strongly into growth again. With us, in this respect, they might be compared to Willows.—CAMBRIAN.

— *Arbutus*es may be cut down with great advantage. Two years ago I cut down a large scraggy tree within 18 in. of the ground, which has now acquired a perfect bush form with fifty or sixty shoots 5 ft. high. They should be cut down at once.—W. V.

WOODLAND WORK FOR MARCH.

THE arrears of work, both in the woodlands and in the nurseries, are so heavy that the greatest activity will be required to get them well under, so as to have everything in readiness for the bark stripping should the season prove an early one. Where the thinning of close plantations, which have been hitherto neglected, is not yet completed, it will be better to defer the work for another winter, than to carry it on after the trees begin to break into bud, as the standards are certain to receive a severe check from late spring frosts if such occur. This remark applies especially to mixed plantations of about twenty years old and upwards, where the trees have become very much drawn up, and, consequently, slender in the stems. Here thinning should now be very cautiously carried out, and the operation is better extended over two or three years. Wherever planting and transplanting are now going on, great care should be taken to keep the roots well covered, as the keen and frosty air of March often proves very injurious to young plants during removal, and a good puddling will prove very beneficial to those which have to be carried any considerable distance. Push forward rapidly the falling of coppicing, so as to have everything cleared from the stools by the beginning of April; also trim and round off badly-out stools, and remove the debris of broken branches and decaying wood, and everything likely to interfere with the free growth of the underwood. In the nursery the spaces which have been cleared of plants may be well manured and dug in readiness for a crop of vegetables, which will prove the best preparation for a future tree crop. A liberal dressing with well-rotted manure, to be followed either by roots or corn, will leave the land in better condition for seedlings than a badly-worked summer fallow. The latter end of March and the early part of April are the nurseryman's best seasons for the preparation of his seed-beds and the sowing of the seeds. In most places very little of this work was done in the autumn, and winter set in too early for those who put off the operation beyond November. Acorns, Walnuts, and Spanish and Horse Chestnuts may still be planted in a good loamy soil, fairly dry and well pulverised. Less covering will now be required than was necessary for autumn-planted seeds. About 2 in. apart will afford the young plants fair nursery space. If placed in drills the plants are more conveniently underfoot, where such is the

practice; but, when the smaller seeds are sown, the young plants afford each other greater protection from winds, cold, and drought. Beech, Elm, Maple, and Sycamore are so liable to be cut off by the late spring frosts that a good part of the seed is better reserved for sowing in the early part of April. The seeds of Alder, Yew, Holly, Hawthorn, Hornbeam, and Mountain Ash should be very lightly and evenly covered with fine soil, which is best sifted over them to a depth of from $\frac{1}{2}$ in. to 1 in., according to the size of the seeds. Much more seed is generally destroyed by too thick than by too light a covering of soil. The stems arising from seeds too deeply buried are more liable to attack than those from seeds lying near the surface, and which, from the sun's early influence, start off at once into vigorous growth. The land intended for Ash keys should be deeply stirred and well pulverised, and it should not be too much sheltered. The seeds of the Pine and Fir tribes require to be thickly sown and well protected from birds, which often prove very destructive to them as they rise from the seed bed. Beds of from 3 ft. to 4 ft. wide are convenient for these, and the seeds require to be sown about as thick as Oatons, or two to the square inch. They flourish best in a soil moderately light and in good condition, not too much exposed to the sun nor too closely shaded. As the plants appear aboveground cover the beds with nets and water occasionally in dry weather. To insure the young plants from frosts stick the small spray of the Elm, Beech, &c., in the beds. Upon very light land, where the plants are apt to become loosened by the wind during the summer, a little finely-sifted soil scattered over the beds will insinuate itself around the stems and fix them.

A. J. BURROWS.

THE KITCHEN GARDEN.

SPROUTING POTATO SETS.

THOUGH this is a common enough practice, it is not so frequently observed as it ought to be. Sprouting the sets is of the greatest importance in unfavourable seasons, when planting cannot be proceeded with, and also in late and cold situations. Sets sprouted about this season and planted out in April or even in May, will produce a crop weeks before those planted without sprouting, though the eyes may be moving. Sprouting, however, requires to be done in an intelligent manner. It is a bad plan to start the tubers in strong heat, as in that case the shoots come weakly, and after they are put out, even if hardened off previously they often go off by canker or damping. The best plan is to start in time and in a moderate heat. We find that the eyes of our main crop seed, if procured in February and laid on the bottom shelves of the fruit room, where the temperature generally ranges from 45° to 50°, and covered over with short straw to keep them dark, push fast enough, and that the shoots are generally 1 in. long or more by planting time. Early varieties need a trifle more heat. They should be packed as closely together on end as they will stand, in boxes or old flat-bottomed hampers, and covered about 2 in. deep with fine, light soil, from which they may be lifted easily when transplanted, with plenty of good roots, and at the same time they can be disbudged if necessary. In transplanting, very little of the tops should be left above ground—if at a season when frost may still be apprehended, none at all indeed.

Unless the weather be very unfavourable, Potatoes forwarded in this way and planted out get hold of the soil and grow just as soon as those forwarded in pots and planted out with balls of soil, a plan which entails a great deal more labour. The sets may, however, be sprouted without rooting, and I am not sure that this is not just as good a plan as the other, while it is certainly more convenient. I once planted out Potatoes that had been started in soil and which had long roots attached to them, and another lot that had been stored in a cellar all the winter, and which had sprouted 3 in. but had no roots, and, if anything, these last grew the fastest. The reason of this, probably, was that those transplanted with roots received a check, while those without roots received none, but were rather encouraged by being transferred to the soil. A collar is as good a place as any in which to start seed Potatoes, if a little light can be admitted to it, as the temperature is usually high enough to cause the sprouts to move gently, and if the Potatoes be spread out thinly on the floor the sprouts will not be weak and drawn.

S.

DALMAHOY AND YORK REGENT POTATOES.

"A. D." asks (p. 206), "Where exists the difference between Dalmahoy and York Regent, except in the imagination?" If "A. D." knows anything of one of these sorts he is certainly totally unacquainted with the other, or he would never have asked such a question. The chief difference between the two sorts named is that the Dalmahoy is a second early kind succeeding the Kidneys, and generally coming in for use during July and August, while the York

Regent is a late sort, rarely fit to lift till October. They are also unlike in flavour, the Dalmahoy being the best of the two in this season, for it is not a keeper like the Regent, while in their foliage they are so unlike that one might tell the different breadths of each a long way off. I have grown the two together for years, procuring the Dalmahoy from a reliable source in Scotland, and the Regents from a Yorkshire dealer. As to Myatt's and Veitch's Kidneys, they are also two sorts.

—“A. D.” might have observed that I neither said, nor meant to imply that the Kidneys which I named (p. 192) were farther distinct in character than being forms of a well-marked type, any one of which was enough to grow. The fact of my only recommending one was sufficient evidence that I did not consider them very different from each other. I am aware of the conclusions arrived at by the Chiswick trials; but, nevertheless, there is a difference in some of the kinds there pronounced so near alike as not to deserve distinct names; this the following instances confirm:—An acquaintance of mine, who yearly grows 10 or 12 acres of Potatoes for seed, asked me to get him any new kinds that made their appearance, which I had reason to think were really good. I procured for him a couple of bushels of Hammersmith Kidney the first year after it came out; they were planted in rows through the middle of a 10-acre piece of ground, beside Myatt's and other Kidneys; but the crop of the Hammersmith variety was a complete failure through rabbits eating the whole of the leaves as fast as any were produced during the season, leaving the stalks as bare as if they had been hand-picked, and not another Potato was touched, although there were at least a score of kinds grown. This was the first instance I ever knew of rabbits eating Potato tops to any extent, but it clearly went to prove that this Kidney was not identical with the others, though the difference thus determined was of a nature that proved nothing either for or against the merits of the tubers. The difference, with little distinction, in kinds bearing different names has led to no end of confusion. I could go into any of the great Potato growing districts and find a dozen sorts different in both their time of coming to maturity and also in their eatable quality, yet all bearing the name of Regent. When speaking of this good old kind I mean the true York Regent, a very different variety from Dalmahoy; this, when true to name, has much deeper eyes, is rougher looking, larger, not so early, and, at its best for using, later than the Regent. Arguing in the same direction, on similar ground to that which “A. D.” takes up, I have heard it said that Patterson's Victoria is a Regent, which, so far as general qualities go, holds good, but it is late in coming to maturity and a very late keeper, properties quite sufficient to make it deserving of the distinct name which it bears.

T. BAINES.

—“A. D.” (p. 205) may be right about Myatt's, Veitch's, and Lee's Kidney Potatoes being alike, but he is wrong as regards Rivers' and Gloucestershire Kidneys. Here no two Kidneys could be more dissimilar. Rivers' with us produces a good crop of ordinary-sized tubers at least twelve days earlier than the Gloucester, while the tubers of the latter are larger than those of Rivers', as are also the stems, although both are grown together on the same piece of ground. Rivers' Kidney we always force in frames, but we would never think of using the Gloucester for such a purpose.—CAMBRIAN.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Potatoes and Frost.—“A. D.” (p. 205) certainly gives common sense advice with regard to the protection of Potatoes from frost. We all do our best, according to circumstances, as to storage, and I consider that “Cambrion” in THE GARDEN of March 1, rather gave us a hint as to how to make the best of a bad job than encouraged neglect. As to the settlement of the question with regard to distinctness between the so-called different varieties of Ashleaf, I cannot quite accept the dictum given at Chiswick as final, being convinced, after several years' trial, that we might as well say all Tea Roses were the same. What an exceedingly bad soil “A. D.” must have the misfortune to cultivate. Regents, I thought, would prove successful everywhere, and however early the disease might come, I always considered that they would be fit to eat, however small. The Regent answers equally well on chalk as on deeper soil, nor can any fault be found with it, except that in very wet seasons it has a tendency to supertuberate. As for American Potatoes, no doubt in their native land they are good; in England all, from Early Rose to Climax, are equally bad, nor has our Patterson's Victoria been beaten, except, perhaps, by its seedling the Queen.—EUGENE E. P. LEGGE, *Dillon Cheney, Dorset.*

Magnum Bonum Potato.—In answer to “B. H. J. S.” (p. 190) allow me to say that I find this Potato, when cooked, to be quite a “flour ball” and excellent in flavour. The only drawback which this

Potato has is its liability to produce many ill-formed tubers. Out of several bushels grown here last year, I do not think I could have selected a peck of what could be called well formed ones. In the case of this variety there was very little disease. It was planted in rows 2 ft. apart, and 2 ft. asunder plant from plant, no manure being put on the ground for one year previous to planting. It should be borne in mind that there is quite as much art in cooking a Potato as in growing it; if more attention were paid to this particular point, we should not hear so many complaints as regards quality.—A. H.

—My experience of Magnum Bonum is the same as that of “B. H. J. S.” only the yield with me was inferior; the Potatoes were uneatable. The sort that does best with me is Patterson's Victoria. R. K., *Devonshire.*

Winter Cucumbers.—Although the season has been very unfavourable for winter Cucumbers, there having been continuous frost and scarcely any sunshine, yet we have had an abundant supply. The sort on which we rely is Rollison's Telegraph, a most prolific variety, four or five fruits showing at almost every joint of new growth, and necessitating constant attention in removing all surplus ones, or they soon exhaust the plants. For ordinary use I find medium-sized Cucumbers preferable to the long exhibition kinds, as, when Cucumbers are required daily, there is a great waste in supplying any other than those which produce fruits from 12 in. to 16 in. in length.—J. GROOM.

Webbs' Perpetual Bearer Cucumber.—Amongst recent introductions this new Cucumber has proved with me to be a very valuable variety. I have grown it side by side with several well-known sorts, viz., Telegraph, Duke of Edinburgh, Berkshire Champion, and others, and find it to be better than any of them. It runs from 18 in. to 20 in. long, good in shape and colour, and excellent as regards flavour. It is also the most prolific Cucumber with which I am acquainted.—R. G.

ANSWERS TO CORRESPONDENTS.

Multiplying Vandas.—I have a large plant of Vanda tricolor, the lower leaves of which are gone. It has near the bottom two side growths so that I could now make it into three rooted plants. Is it safe to do this? and is this the time to do it? It has flower spikes just appearing; Vanda savais the same.—A. A. [Vandas may be divided and potted in fresh pots almost at any season, provided they have young roots attached to them. Heel them off after shaking the plants clear of the compost, and pot them to the lower leaves, raising them to form when finished a good convex surface. If you are careful, the operation will not interfere with the efflorescence of the flower spikes. Sometimes, however, Vandas make larger “shows” than their strength warrants, and the flower spikes, especially in an embryo state, go off. All Vandas, in fact, require handling and potting down as they grow to some size, to keep up a good appearance amongst their associates in the Orchid house.—J. ANDERSON.]

Goat Moth Caterpillars.—In one of our Rose borders I found a large caterpillar, which, I am told, is that of the goat moth. How can I keep it? what does it eat? and what length of time must elapse before it reaches a perfect state?—W. C. B. [The caterpillar of the goat moth bores into the stems of various trees, forming long galleries in which it lives feeding in the wood of the tree. Within these galleries it generally becomes a chrysalis, but sometimes it leaves the tree and undergoes its change to the chrysalis state in the ground at the root of the tree. The caterpillar is about three years in attaining its full size, when it is about 4 in. in length. If the caterpillar in question be full grown it may become a chrysalis if placed in a box, at the bottom of which is about 4 in. or 5 in. of fine moist earth. If not fully grown it would, I imagine, be very difficult, if not impossible to rear it without placing it in a tree into which it could bore, when, of course, the caterpillar would be lost. If “W. C. B.” would send a description of the caterpillar, it might be possible to tell him if it were that of the goat moth or not.—G. S. S.]

Holly Hedges.—I want to plant a Holly hedge against a wall facing the south as a background for a border of herbaceous plants. What time of the year should I plant? What sized plants would be best? and does the ground want any particular preparation?—A. M. A. [Hollies require ground in which they are to be planted to be fairly dry naturally, or, if not, made so by draining; but a border that will answer in this respect for herbaceous plants will do for the Hollies. If there be a sufficient depth of soil to admit of the ground being dug 15 in. or 18 in. deep it should be treated putting in a good dressing of rotten manure, to which few plants are more partial than Hollies. Plant either in the middle of April or beginning of September; the plants may be either of the ordinary trade size for hedges or up to 5 ft. or 6 ft.; this is a mere question of price. If immediate effect be required the larger ones will give it at once, but whatever size is employed the plants should be such as are in a condition for removal without serious check by having been transplanted not more than two years ago. Whichever time is decided upon for planting, they should not be longer out of the ground than can be avoided; they must be thoroughly soaked with water when put in, and,

if the work be done in April, again well watered at such intervals through the summer as they may appear to require it by the more or less dry weather which ensues. The larger the plants are the more attention will they need in this respect. If not planted until September, one good watering at the time of planting will be enough. Plants large enough for the wind, to have much hold upon them will require staking to prevent their being disturbed by it.—T. BAINES.]

Eucalypti.—*Eremouth.*—Seeds and plants of *E. amygdalina* and other Eucalypti may be had of Messrs. Laing & Co., Stanstead Park, Forest Hill; from Messrs. E. G. Henderson, Pine-apple Place, Maida Vale, and other metropolitan nurseries.

General Index to Back Volumes of the "Garden."—THE GARDEN has now reached so many volumes, that, as a subscriber from its commencement, I venture to suggest the desirability of a General Index being published; say up to the end of last year. It would be a great boon.—M. W. [We intend publishing a General Index to the back volumes of THE GARDEN, at the end of this year or next.]

Books.—J. H. W.—There is no such book anywhere published. The species of plants are so numerous, that no one work could deal with them as you desire. Your only plan is to get different books; as, for example, "Williams" for stove and greenhouse plants, and "Hardy Flowers" for border plants, &c.

Names of Plants.—*Cypress.*—1, *Pinus Pinaster* var. *maritima*; 2, *Thuja occidentalis* var. *sibirica* Hort.; 3, *Cupressus Cernegyna*; 4 and 5, *Cupressus Lindleyi*, but cultivated as [Knightiana and elegans]; 6, *Fitzroya patagonica*, H. & Son.—*Saurauiana africana*, H. Hoss.—*Dendrobium Pierardi*, W. B. H.—*Daphne Mezereum*. T. B.—*Dendrobium nobile corulescens*.

Mutisia decurrens.—I shall be very much obliged to any one who will kindly tell me where this plant can be obtained. I have been trying to get hold of it for some time, and Messrs. Osborne, of Fulham, have been helping me, but hitherto in vain.—H. EWBANK, St. John's, Ryde.

Liberian Coffee Seeds.—How long do these take to germinate? and what is the most suitable temperature, and best method of growing this Coffee?—W. G.

STORING ICE.

It may be that I am wrong and that Mr. Thomas Williams (p. 161) is right in reference to this subject, but some of his suggestions respecting storing ice seem unsound in principle. I have always understood that a lump of ice could only melt by the action of heat on its outer surface, and that the object of stacking in the form of a cone was that the heap might expose the least amount of surface to the action of the air in proportion to its bulk. No drainage is needed except where melting is going on, and that only takes place at the sides of the heap near the walls of the icehouse. No melting takes place in the centre of the heap, and it of course follows that there is no need for drainage there. Yet Mr. Williams recommends running a chimney stuffed with straw up the centre of the stack for drainage purposes, but which is simply a device for creating the very evil that it is intended to cure. If we desired to make an ice house in which the ice would waste quickly nothing better could be devised than Mr. Williams' plan, if the circumference of the central fue was only enlarged a little, as by such means the heap of ice would be exposed to the air both inside and outside, and would waste proportionately quick. As to the use of straw, in our house here, which is exactly the shape of that figured in THE GARDEN, only that it has double walls, no straw is used; the ice keeps just as long without it, and we have tried both plans, packing the bundles of straw exactly as Mr. Williams recommends, but round the sides only. Your correspondent says, "Why should we pound our ice in filling the house?" The reason, I should imagine, is very easily given. It is pounded because one can get twice or three times more ice into the same space by doing so, than could otherwise be got into it. This any one may convince himself of, by filling a box with ice packed in its rough state, and then breaking it up fine and observing how its bulk is reduced. Storing Wenham Lake ice is a very different matter from filling ice houses in this country. The blocks are sawn out square, and packed methodically together so that no space may be lost, but such ice as we are able to get during our fickle winters, is not thick enough to be manipulated in this way, and can only be stored economically and expeditiously by being pounded to pieces, and the smaller it is broken the better. If ice were built up in layers, formed as Mr. Williams suggests, I have no doubt it would keep better; but can he tell us how this is to be done in an ordinary way, when, as often as otherwise, the ice is so thin that it will hardly stand pulling out of the pond. The building up suggestion is impracticable. C.

—My remarks on storing ice (p. 161) I felt sure would evoke criticism and comment; but, so far, I have come off better than I anticipated. Routine work is not always rational work, and practice too often sanctions a thing for which it would be hard to find a reason, and whoever has the boldness to question, or to depart from, an anti-

quoted idea, or practice, is almost certain to meet with reprobation. Mr. Dennis, in criticising my communication (p. 191) has gone further than was necessary. I never hinted about "giving the palm" to the rough and ready method, considering the storing of ice a very costly luxury. What I really meant was that, as not one in a thousand could afford to build an ice house, thousands may enjoy the luxury of ice with little more trouble than that required to store a mound of Potatoes. What I meant by strawing ice wells in an "ineffectual manner" does not imply careless or slovenly work; straw applied in a loose or literary manner is "ineffectual," compared with the material used in a compact, straight, methodical manner. Mr. Fairweather seems to think (p. 191) that lining with straw is useless; but, where straw is employed (and I am of opinion that in most cases it will continue to be used), loose straw, as commonly applied, is no more to be compared to straw placed in a methodical manner than a rubble wall can be compared to squared stone. Mr. Dennis states that straw applied loose is superior, when well done, to straw tied up in a straight, systematic manner, and asserts that it will act exactly in the same manner as regards drainage. I am afraid Mr. Dennis will stand alone in the latter opinion. It is tantamount to declaring that every hay stack, Corn stack, or thatched building needs no thatching, properly so-called, but may have the straw put on in a loose manner, as in that way it will carry off the rain equally well. Surely that cannot be correct; loose straw will take in water as quickly as the other; so will a sponge, and the one will part with it almost as soon as the other. Mr. Dennis further enquires "how often would an opportunity occur of filling an ice house with ice and water?" and answers "once in twenty years." I reply, not twenty hours. It is always supposed to be frosty weather when ice houses are being filled, and water applied at the same time will, by contact with the ice, be almost immediately congealed, and will, if the mass be high and large, never percolate to the bottom, and that is the reason why I advocated the process to be done gradually, weather permitting, but it may be done at once. Fill a tall cylinder with broken ice, place it out-of-doors in frosty weather, when full of ice apply water, and Mr. Dennis will find that the converting the water into a solid state, is not a phenomenon that may only happen once in twenty years.

Ormskirck.

THOMAS WILLIAMS.

NOTES FROM KEW.

Hardy Plants.—Most conspicuous among the early spring favourites are the numerous kinds of Crocuses, which exhibit considerable diversity in form and colour. The new and rare *C. etruscus* is in fine condition; it has numerous delicate mauve blossoms, and a golden ring at the inner base. *C. Weldenii* is an exquisite little gem, bearing snowy white blossoms and bright orange stigmas. It is regarded by some as a variety of the ordinary *C. biflorus*, but such a distinct plant is—at least, for horticultural purposes—deserving of specific distinction. It is a native of Dalmatia, whilst *C. biflorus* and its obvious form, are natives of Italy. By-the-way the non-striped form of *C. biflorus* is also very distinct, the upper half of the flowers being pale mauve, and the lower part having an orange tinge. It is called here *C. biflorus striatus*. The small form, pusillus, merely differs from the type in the matter of size, as does also argenteus in the other direction. The old favourite Cloth of Gold Crocus is eclipsed by few; the rich orange of the inner part of the flower charmingly contrasts with the velvety-black of the outside. *C. suaveolens* is a neat little kind, much in the way of the better-known *C. Imperati*, but smaller, and having, in addition, a pleasant perfume. One of the finest of the whole set is *C. banaticus*, whose flowers are nearly as large as those of the garden forms of *C. vernus*. They are bright violet purple, and have a conspicuous V-shaped marking of deep purple on the outside tips of the blossoms. It has also broader leaves than the majority of cultivated kinds. It is a native of the mountains of Hungary and Transylvania. *C. Fleischeri* ranks highest on the score of rarity, if not on that of beauty. Its flowers, which are creamy-white, are elegantly pencilled with deep purple lines. The fibres on the bulb of this kind are distinct from those of any other Crocuses, being interwoven in a very remarkable manner. It inhabits limestone hills near Smyrna. The Siberian Squill (*Scilla sibirica*) and the two-leaved kind (*S. bifolia*), with its various forms, were the first to peep above ground this season. They associate charmingly with Krelage's variety of the netted Iris (*Xiphion reticulatum*). This, though not so brilliant in colour as the type, is highly desirable, on account of its opening its flowers a week or two earlier. It may at a glance be recognised by the violet colour of the falls, whereas in the original kind they are of a deep rich purple. The beautiful Saxifraga Barseriana is well represented, and amongst the specimens one may detect well-marked forms differing in the size of the flowers, the length of their stalks, and also in the habit, some being of a loose, spreading growth, others forming compact, dense tufts. S.

Rocheliana is scarcely inferior to the last, though not so free flowering, and it has smaller flowers. The opposite-leaved Saxifrage (*S. oppositifolia*) and its white variety be seen on every rockery, more especially the lovely Pyrenean variety, which is considerably larger in all its parts than the type and equally free flowering. The form *rubra*, of which a coloured plate appeared in THE GARDEN last year, is a shade darker in colour than the original.

Hardy Shrubs.—Though not very showy, Standish's Honey-suckle (*Lonicera Standishii*) deserves a place against a wall on account of its early flowering, and also on account of the delicious perfume yielded by the blossoms; the latter are about 1 in. long, and of a creamy-white colour, borne profusely on naked branches. *Jasminum nudiflorum*, too, bears golden-yellow blossoms in profusion. It is a plant that cannot be too highly recommended, on account of its early flowering. Handsome, both in foliage and flowers, is the Nepalese Barberry (*Berberis nepalensis*), a capital shrub for a wall, a position in which it thrives more vigorously than in a shrubbery.

Greenhouse Plants.—Several elegant climbers well deserve a passing notice, such as *Kennedyia rubicunda*, a New Holland plant, producing a profusion of large Pea-shaped blossoms, of a deep red colour. *K. ovata* and its variety *rosea*, very desirable evergreen kinds, are now bearing a copious supply of dense clusters of small light purple flowers, which are very useful for cutting purposes. One of the handsomest of the Honey-suckles is the North American evergreen kind (*Lonicera sempervirens*), which is now very showy, bearing, as it does, numerous clusters of scarlet and orange-tipped blossoms. A curious as well as handsome trailer is the Chinese five-leaved *Akebia* (*A. quinata*), bearing, as its name implies, leaves with five oblong leaflets and loose clusters of barren and fertile flowers, the latter twice the size of the former, and both of a deep claret colour. *Hardenbergia Comptoniana* at first sight reminds one of the ovate-leaved *Kennedyia*, but differs in the form of its leaves and also in the much darker colour of the blossoms. All the above can be strongly recommended for training to the rafters of even small greenhouses, as they are graceful in habit and are abundant flowerers. As a basket plant few are more suitable than the profuse flowering *Crassula* (*C. profusa*), the slender branches of which hang gracefully over the sides of the pots, and are literally covered with clusters of white, star-like blossoms; it delights in a dry atmosphere, and is therefore admirably adapted for room culture.—W.

NOTES OF THE WEEK.

White Lilac.—We have lately cut in this great quantities, and of the purest white. We dig up large bushes, 8 ft. or 9 ft. high, of the common large-flowered purple kind, with good balls, and set them in corners of early Vineries and Peach houses. A temporary box of bricks is constructed for enclosing soil round their roots. They are kept syringed in a water, like other occupants of the house, and, with the exception of the partial shade obtained from the Vine leaves, they have had all the light that there has been. The branches have been tied up to economise space, and thus bundled together, they have looked like pillars of snow. Lilacs produced in this way is preferable to that grown in darkness, as the foliage is of its natural colour, and in the case of flowers, even for table decoration, there is nothing like their own foliage for garnishing.—JAMES GROOM, *Linton Park, Maidstone*.

Double-spathed Arum Lily.—The most striking flower which we have seen for a long time is a noble specimen of a double-spathed Arum Lily (*Calla ethiopica*) grown in Mr. Leaf's garden at Pain's Hill, Cobham. The spathe, taken together, measured nearly 16 in. across, and each, separately, 6 in. in diameter. Double spathe are not uncommon with this Arum, but we never saw both so perfect as in the case just referred to.

Hardy Flowers at Tooting.—The few days sunshine which we have had have done much to forward hardy flowers. In Mr. Barr's ground Crocuses make a fine show, and Hepaticas are equally good; they consist of single pink, double pink, single blue and purple, and even small plants represent complete masses of brilliant blossoms. Cyclamens have not done so well out-of-doors this year as usual, excepting those in pots in temporary frames, which make a fine display. They consist of *C. coum*, rose; *C. Atkinsi*, white; and *C. ibicolum*, dark rose. Snowdrops, especially *Galanthus plicatus*, are very fine; such bulbs as were moved last year and replanted not too thickly in beds bear very large blossoms, and show that, whilst allowing bulbs to stay in the ground undisturbed for years is calculated to increase the quantity of blossom, it is by no means the best method of obtaining fine flowers. *G. Elwelli*, a new and pretty Snowdrop, is now in flower, and the Winter Aconite forms quite a carpet of green-

ish-gold flowers. The white Hoop Petticoat Narcissus (*N. monophyllus*) is blooming well in a raised frame, and other kinds of Narcissus are fast coming into bloom, as are also Squills. *Aubrietia deltoidea variegata* (the golden-leaved *Aubrietia*) is a pretty plant, now in flower in Mr. Parker's grounds, in which we also noticed the Winter Snowflake (*Leucojum vernum*) in full beauty. Iris *Krelagei* is opening several flowers, and *Narcissus minor*, the earliest of the Daffodils, is in full bloom.

Rhododendron arboreum at South Kensington.—The fine *Rhododendron arboreum*, for which the great conservatory in the Royal Horticultural Gardens at South Kensington is celebrated, is now in great beauty. It is a noble specimen, and bears hundreds of trusses of bright crimson-scarlet blossoms.

Primula Eva Fish.—This is one of the most attractive of double Primulas. Its flowers, which are very large and double, with fringed edges, are bluish-violet, a colour which contrasts well with the white flowers of *P. Blushing Beauty*, both of which, together with many others, may now be seen in good condition in Messrs. Henderson's nursery at St. John's Wood, where they originated.

Cornus Mas variegata.—This, in addition to the beauty of its foliage in summer, is valuable in the shrubbery in winter, thickly beset, as it is, with clusters of bright yellow buds. In this condition we find plants of it in Mr. Parker's nursery at Tooting, where, among other trees and shrubs, they have, at this comparatively flowerless season, an interesting appearance.

Iresine brilliantissima.—Where highly-coloured plants are desired for ribbon or carpet gardening this cannot fail to be a favourite. It is dwarf in habit, bright rosy-crimson in colour, and in every way much more effective than any other plant of the same class. It originated in Mr. Cannell's nursery at Swanley.

Hardiness of Aralia Sieboldi.—That this plant is perfectly hardy may be proved by the fact that examples of it in Messrs. Osborn's nursery at Fulham, have withstood the late severe winter without much apparent injury, and this is by no means a favourable situation. It is a noble plant in shrubbery borders, and its perfect hardiness gives it additional value.

Selaginella Wallichi.—This is one of the most useful of Club Mosses for pot culture. It throws up long, graceful fronds of a glistering bronze colour, which, for vase decoration, are equal to those of any Fern used for that purpose, and well-grown plants of it might be made available for dinner table decoration. It is grown well by Mr. Williams at the Victoria nursery, Holloway.

Hardiness of Ficus minima.—This is one of the neatest and best of plants for covering walls in plant houses, and it may also be used with advantage for many purposes out-of-doors, it being much more hardy than is generally supposed. We noticed a plant of it growing on a wall in Mr. Parker's nursery at Tooting, which had withstood the late severe winter without sustaining any apparent injury; whilst the larger kind, *F. repens*, growing in the same place, is almost killed.

Tree Pæonies.—There will shortly be a fine display of these in Messrs. Henderson's nursery at Pine-apple Place, where, as elsewhere, they are found to be valuable for conservatory decoration, and for supplying out flowers. They are grown in cold houses or frames till the bloom buds show themselves, when they are subjected to a little heat, which has the effect of speedily bringing them into blossom in a cool house. These flowers last for a considerable time in perfection, and being large, handsome, and sweetly scented, they have a fine effect when associated with *Deutzias*, *Amaryllises*, and similar plants in bloom.

The Rose House at Gunnersbury.—This is, perhaps, one of the best Rose houses to be found near London. It is span-roofed, with a narrow brick bed all round and a large bed in the middle. In the narrow beds are planted Tea Roses, one to each rafter, and these are trained under the roof, but they are confined to a space of 2 ft. in width so as not to obstruct the light too much. A hedge of *Gloire de Dijon* occupies the centre of the bed, and the remaining space is filled with dwarf Hybrid Perpetuals, which, although they get a little drawn on account of being a long way from the glass, supply a large quantity of buds for cutting. Many hundreds of buds, just expanding, may now be found in this house.

Mr. Little's Cyclamens.—These have long been noted for their excellence, both as regards growth and quality of bloom. This year, however, the plants are not so satisfactory as usual, owing to some mismanagement over which the owner had no control, but as regards richness of colour and strain generally rapid strides are still being made. Compactness of growth and shortness of flower stalks are aimed at rather than size, and by means of skilful cross-breeding,

perfection, from a florist's point of view, will doubtless ere long be attained. In a long, light, airy house, Mr. Little has at present such a display of *Cyclamen*s as are seldom has an opportunity of seeing in any one place, and in colour they vary from pure white to the deepest purple and crimson. These are backed up by some finely grown seedling *Amaryllis*es, *Azalea*s, *Pelargonium*s, and *Primula*s.

Salvia splendens.—An improved variety of this brilliant Sage has been flowering freely in Mr. Cannell's nursery at Swanley. Its leaves are wholly different from those of the type, being much larger, round, and deeply serrated on the edges, whilst the flowers, which are produced in large trusses, are treble the size of those of the common kind.

Grapes at Oxenford Castle, Dalkeith.—Just now Mr. Anderson has a magnificent display of Grapes in his stove shelves in bottles. They consist of not less than 200 bunches of Lady Downes, Alicante, Pearson's Golden Queen, Gros Colman, and Muscat of Alexandria. It is somewhat difficult to keep good Muscats so late, but nevertheless the bunches look well among their associates, and scarcely anything else is eaten so long as they last. Golden Queen looked plump and fresh, and was as good in flavor as any yellow Grape, with the exception of the Muscat. The conserving room is new, and at present unheated, but Mr. Anderson kept two paraffin lamps going night and day during the severe winter though which we have passed, and which did the work effectually. Grapes look tempting at any time, but in artificial light, suspended from so many Moselle bottles, the effect was indeed charming.—JAMES ANDERSON, Meadowbank Nurseries, Uddingstone, N.B.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

MARCH 11.

THE most striking features on this occasion were the grand banks of *Cyclamen*s supplied by some of the best growers of that flower, and attractive groups of plants from some of the principal London nurseries. The conservatory, too, in which the show was held, was in itself very attractive, many of the plants which it contained being finely in flower.

First-class Certificates.—These were awarded as follows:—

***Ipsaea speciosa* (Philbrick).**—A terrestrial Orchid, with beautiful, waxy, lemon-coloured flowers, delicately scented.

***Amaryllis Virgil* (Veitch & Sons).**—A white, crimson-striped kind with very broad, well shaped, recurved petals, evidently the forerunner of a fine breed of *Amaryllis*es.

***Azalea Empress of India* (Van Geert).**—A dwarf, free-flowering kind valuable for decorative purposes, the flowers being large, semi-double, and bright pink in colour, blotched with purple.

***Cymbidium Lowianum* (Low & Co.).**—A kind resembling *C. giganteum*, having long, graceful flower-spikes, and large, greenish-yellow, wax-like flowers, having a rich velvety crimson lip.

***Cyclamen persicum picturatum* (H. B. Smith).**—A variety with mottled leaves, and very large flowers with white, rose-edged petals purple at the base.

***Cyclamen Crimson King* (H. B. Smith).**—A sort dwarf in habit, bearing fine broad-petalled flowers of a deep crimson colour.

***Davallia Mariasi* (Veitch & Sons).**—A dwarf species, with finely cut leaf-like pinnae, and well adapted for pan or basket culture.

Medals were awarded as follows:

To Sir Trevor Lawrence for a group of Orchids, small Banksian. To Mr. Bull for a collection of new and rare plants, silver-gilt Banksian. To Mr. B. S. Williams and Messrs. Osborn & Sons for miscellaneous groups of plants, silver Banksian. To Mr. H. B. Smith, Ealing, for a group of *Cyclamen*s, large gold Banksian. To Mr. Edmonds for *Cyclamen*s, silver-gilt Banksian. To Mr. Clarke, Twickenham, for *Cyclamen*s, silver Banksian; and to Mr. Ford, for Apples, silver Knightian medal.

Groups of Plants.—From Messrs. Veitch & Sons, Chelsea, came an attractive group of plants, consisting of finely-berried standard and bush Aucubas, new and rare *Amaryllis*es, *Cyclamen*s, and *Primulas*, backed up by Palms, and other fine-foliated plants. In this group was also a hybrid Cattleya (*C. Vitchii*), the result of a cross between *C. labiata* and *C. crispata*; it has a delicate violet-coloured flower, having a rich claret-coloured lip. *Camellia reticulata* fl. pl. from the same firm, was noticeable on account of its distinct character, its flowers being stiff and waxy, and of a deep rosy-carmine colour. Mr. Bull exhibited a miscellaneous group of new and rare plants, amongst which were well-grown graceful specimens of the arching-leaved, finely-striped *Carulago recurvata variegata*, the twining-stemmed *Philodendron gloriosum*, no less *Cycas* and Palms, *Dracenas*, and Orchids. Mr. B. S. Williams contributed an effective group of plants, consisting of finely-berried Aucubas, several new *Amaryllis*es and *Primulas*, including pansful of *P. denticulata*,

associated with which were finely-flowered examples of *Dendrobium Wardianum*, *Odontoglossum Alexandra*, and *Lady's-sippers*. Messrs. Osborn & Sons, Fulham, exhibited an attractive group of plants, amongst which were well-flowered *Rhododendrons*, *Amaryllis*es, *Deutzias*, *Spiraeas*, *Abutilons*, and *Azaleas*, the whole being relieved by Palms, Ferns, and other fine-leaved plants.

One of the finest collections of Orchids ever exhibited at these meetings was one shown on this occasion by Mr. Spyers, gardener to Sir Trevor Lawrence. They were both unusually well grown and profusely bloomed. Among them were fine varieties of *Dendrobium Wardianum* and *D. crassinode*, having hundreds of large, finely-formed blossoms; *D. nobile*, masses of blossom, and the pretty primrose-coloured *D. luteolum*, grown on a wooden raft, profusely laden with flowers. With these came a well-grown specimen of *Cymbidium eburneum*, bearing eight ivory-like flowers and four buds; *Lady's Sippers*, of various sorts; finely-flowered specimens of *Odontoglossum Alexandra*, bearing graceful spikes of large blossom beautifully spotted; *D. nebulosum pardinum*, a kind generally admired on account of its large, waxy, brown-spotted flowers; and the brilliant orange-coloured *Lælia harpyllia*, and some fine examples of *Phalaenopsis*. Mr. Benham, gardener to Earl of Stradbroke, Henham Hall, exhibited four finely-flowered plants of *Phalaenopsis Schilleriana*, bearing collectively between two and three hundred blossoms. Mr. Cannell, of Swanley, again sent a magnificent stand of blossoms of *Zonal Pelargoniums*, the colours being of unusual brilliancy and the flowers of superior form. The best kinds were Kleon, dark scarlet; Mrs. Leaver's, rose; Henry Jacoby, crimson; Lizzie Brooks, lively scarlet, very large; and White Vesuvius. A grand bank of *Cyclamen*s, made up of finely grown plants, was contributed by Mr. G. B. Smith, of Ealing, Mr. Edmonds, of Hillingdon, and Mr. Clarke, of Twickenham. Mr. Smith's collection was remarkable for the excellence of the white-flowered kinds; Mr. Edmond's had very large flowers; and Mr. Clarke, blooms possessing colours seldom seen in *Cyclamen*s.

Miscellaneous Subjects.—Messrs. William Paul and Sons, Waltham Cross, exhibited an extensive collection of cut blooms of *Camellias*, consisting of nearly fifty of the best known kinds, including finely developed blossoms of *Fimbriata*, *Imbricata*, the fine, red, wax-like *Mathotiana*, and the pretty pink white striped *Madame de Sreklaff*; also *Beauty of Hornsey*, *La Reine*, and others. A few Japanese *Primulas* having flowers with distinct colours, came from the Society's Gardens at Chiswick; also well-flowered plants of *Imantophyllum miniatum*. New *Primulas* of the denticulata type were also shown by Mr. Ware, of Tottenham. Messrs. Veitch and Sons contributed a basketful of plants of a new *Dracena*, from the South Sea Islands, named *D. Princess Marguerite*. It is compact in habit, and its leaves are of a glistering cream colour, and sometimes striped with green and rose. Mr. James, Isleworth, showed blossoms of *Cinerarias* of great excellence; and Mr. Bland, Cranbourne Court, sent a basketful of finely-flowered *Neapolitan Violets*. Mr. Ball showed *Neptunia ensifolia*, *Adiantum bellum*, and *Pteris umbrosa cristata*. Mr. Paul furnished a bushy, glossy-leaved, white-flowered *Camellia*, named *Niña Egeria*, which was much admired; and Messrs. Osborn exhibited a good yellow-flowered *Abutilon*, named *Yellow Prince*. Mr. Cannell sent cut sprays of *Fuchsia splendens*, in good condition; also plants of *Ageratum*, Cannell's dwarf. Mr. Buchan, Wilton House, Southampton, sent a flowering plant of *Maxillaria Harrisonia Buchaniana*; also fine varieties of *Odontoglossum Andersonianum*, and *O. Alexandra*. The last named Orchid also came from Mr. Green, gardener to Sir J. Macleay, who likewise showed a bloom of *Vanda Cathartica*, which had been cut from the plant three weeks, and which was still in good condition.

Fruit and Vegetables.—One of the finest collections of Apples perhaps ever shown at this season of the year was exhibited at this meeting by Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., Leonard's Lee, Horsham. It consisted of fifty dishes of plump, sound, highly-coloured fruit. Among the best may be mentioned *Wadhurst Pippin*, *Poor Man's Profit*, *Alfriston*, *Northern Greening*, *Norfolk Beefing*, *Blenheim Orange*, *Ribston Pippin*, *Golden Reinette*, *Pronger's Seedling*, and *Sheep's Nose*. Mr. Divers, Maidstone, also sent several good dishes of Apples, and Mr. L. Killick, of Lingley, showed a collection of Potatoes of fine quality. Messrs. Sutton & Sons contributed several kinds of Rhubarb.

***Erica propendens tubiflora*.**—This ranks amongst the prettiest of soft-wooded Heaths, and is one which deserves a place in every collection. It flowers profusely, in habit it is compact, and the whole appearance of the plant when in bloom is most satisfactory. Were I limited to three kinds of soft-wooded Heaths, I would choose *Erica byrnalis*, *gracilis*, and the variety under notice. Heaths are and have for some years past been as it were under a cloud, their decorative value not being so fully appreciated as formerly. Although not quite so easily and quickly grown as the majority of those plants which are relied upon for conservatory and window decoration, they are by no means difficult to grow. If cut back and potted early in good fibrous peat, placed in cold frames, and from thence set out in the full sun, they will form useful bushy little specimens, and the soft neutral tints which many of them display, render them valuable for associating with shades of colour of a more glaring and pronounced character.—J. C. Byfleet.

KEW GARDENS.

On Thursday night, the 6th inst., Sir Trevor Lawrence directed the attention of the House of Commons to the existing regulations for opening these gardens to the public. He said, the outlay of public money on these gardens was very large. Last year it was, in round numbers, £20,000, and this year it was somewhat over £18,000. This constituted one-sixth of the whole amount voted by Parliament for the parks and pleasure-grounds of the United Kingdom. The number of visitors to Kew was constantly increasing. In 1877 it was 678,972, being considerably larger than the number of visitors to the British Museum, exclusive of the reading room. On the occasion of two Bank Holidays last year close upon 60,000 visitors entered the gardens in one day. One proof that good had been done by the movement for extending the hours during which the gardens were open to the public was afforded by the fact that on Bank Holidays the gardens were now open at 10 o'clock instead of 1 o'clock, as was formerly the case. That the change was appreciated was shown by the circumstance that on Easter Monday 4,000 people, and on Whit Monday 5,000 people, entered the gardens before 1 o'clock. While agreeing with the directors that in all matters connected with Kew botanical science had a paramount claim, he showed, by quotations from the reports of Dr. Lindley and Sir W. Hooker, that the gardens ought to become an efficient instrument for refining the taste and for increasing the knowledge and rational pleasure of the middle and lower classes. At present the gardens were opened daily at 1 o'clock and closed at sunset. At Dublin, however, the Botanical Gardens were open from 10 to 6. At Edinburgh the Botanical Gardens were generally open daily, except on Sundays, from 6 to 6; from daylight to dark in winter, and from 6 a.m. to 8 p.m. in June, July, and August. The Jardin des Plantes was open daily from 8 o'clock till dark. The Botanical Gardens of Berlin were open for nine hours every day, except Saturday and Sunday; but although they were entirely closed on two days of the week, they were in the course of each year open for a longer period than Kew Gardens. At Hamburg the Botanical Gardens were open from sunrise to sunset, and at Geneva they were open every day during daylight. The Botanical Gardens at Rouen, Caen, and other places in France were also open daily during daylight. Sir Daniel Cooper stated that at Sydney the Botanical Gardens were open from 6 a.m. to 3 p.m. in summer, and while there was daylight in winter, adding that they were a general resort of residents of the city during all hours of the day. These gardens were open much more liberally to the public than those at Kew, and when it was said that it was impossible to do at Kew what was done elsewhere, he might fairly ask why it should be so? It was alleged that there was no real demand for opening the gardens, except a local demand; but the vestries and local bodies of the West of London and the suburbs, almost without exception, had memorialised the House in favour of an early opening. He concluded by moving—"That it is desirable that the Royal Gardens at Kew should be opened to the public at 10 a.m. on week days, with such reservations as may be found expedient."

Mr. T. CAVE seconded the motion.

Mr. GERARD NOEL said there were two strong reasons against the proposal. In the first place, it would very materially add to the annual expenditure; and, in the second place, it would alter the character of the gardens, looking to the purpose for which they were originally established. The gardeners went to work in the morning and remained till 12 o'clock, when they went to dinner; after that they appeared in the gardens as constables, and if the gardens were opened at 10 an increased staff would be necessary, at an expense of from £1,500 to £2,000 a year. He did not think there were any sufficient grounds for this additional outlay. On the Bank Holiday in August last year the gardens had been opened at 10, when the number of visitors was about 53,000. Of these not more than 4,000 entered before 2 o'clock. Between 10 and 11, only about 600 were admitted; between 11 and 12, 1,200; between 12 and 2, about 2,000. This, he thought, showed that the public had no particular desire to enter the gardens before 1 o'clock. The daily average number of persons waiting for admission at the five gates was in August, 1877, 43; in September, 32; in October, 12; in November, 4; in December, 3; in January, 1878, 3; in February, 3; and in March, 5. If the arboretum were opened at 10 o'clock an additional staff of 25 or 30 men would be required, and new regulations would have to be made. At all public institutions there were restrictions on the admission of the public. For instance, the British Museum was open to the general public four days a week; Windsor Castle, five days; the National Gallery, four days; Hampton Court, five days; South Kensington Museum, the most popular institution in London, three days; and the Tower of London, two days; while Kew Gardens were open every day of the week, Sunday included. They were open until dusk, which meant half-past 8 o'clock in summer, and they were closed

only on one holiday, namely, Christmas Day. There really was no ground of complaint, for there was no other institution from which the public derived so much advantage in the shape of unrestricted admission. Persons taking a special interest in botany and horticulture were admitted at 8 o'clock in the morning. He had received deputations on the subject, and also memorials signed by 500 of the most eminent botanists in the country, who, one and all, urged the Government not to assent to the proposal. No doubt the motion was brought forward with the best intentions, but it would be disastrous to the best interests of the gardens, and he therefore hoped the House would support him in opposing the motion.

Mr. M. HENRY was greatly disappointed with the answer of the Chief Commissioner, who had trifled with the real question, because for this purpose the gardens might be divided into two portions, and that which was purely botanical could be closed while the rest was open, and three or four policemen would afford complete protection to the arboretum in the early part of the day. Some prejudice was introduced by speaking of this as a local agitation; he had no local interest in it, and he felt that it was no argument at all to say that local residents, who did nothing wrong by living at Kew, should be denied a privilege because it would improve the value of their property. He hoped the right hon. gentleman would review his decision.

Mr. A. M'ARTHUR supported the motion. Other gardens of a similar nature were thrown open to the public, and the same might very well be done at Kew.

Mr. ASHLEY also supported the motion. London, he said, was the only great town in Europe that did not give its gardens the whole day to the public.

Mr. FAWCETT said the subject was one of general, and not of merely local, interest. No evidence whatever had been adduced to show that scientific research would in any way be interfered with. They were told that a memorial against the proposal had been signed by 500 scientific men. He had some experience of scientific memorials, and he knew that when one or two eminent signatories were obtained it was very easy to get a number of others to follow. The First Commissioner of Works had spoken of the great expense that would be incurred by the proposed change, but in almost the same breath he had emphasised the fact that the early visitors would probably be very few; so that from the right hon. gentleman's own point of view the argument from expense was inadmissible.

Mr. A. MILLS pointed out that it was evident, from the experiment that had been already tried on a Bank holiday, that a very small proportion of the class which it was sought to benefit were likely to avail themselves of the opportunity afforded. Of 53,000 Bank holiday visitors on a recent occasion, no fewer than 54,000 entered the gardens after two o'clock. It was, therefore, a delusion to suppose that to open the gardens early would be to confer a boon on any considerable number of persons. After all, the question was, as a matter of fact, a conflict between botanical science and the owners of villas at Kew and the neighbourhood, and the House would have to decide whether the gardens were to be kept up in such a way as to reflect credit on the directors and on the nation.

Dr. PLAYFAIR said that as it was admitted on all hands that the early visitors to the gardens would not be very numerous, the question narrowed itself to this—whether the convenience of the inhabitants of Kew outweighed the disadvantage of the proposed change. He would remind the House how high was the character of Kew Gardens, and how deserved was the great reputation of the scientific staff there employed. The hon. gentlemen who had brought forward the motion had mentioned the Irish and Scotch gardens; no doubt the hours for opening them were earlier, but Edinburgh was not so vast a city as London, and those who frequented its gardens early in the morning were exclusively students. The supporters of the motion had dealt somewhat unfairly with what had fallen from the First Commissioner of Works with regard to expense; for the point of the right hon. gentleman's argument was that after the admission of the public the gardeners ceased to be gardeners and became watchmen, thus necessitating an increase of the permanent staff. They were hardly justified in making the change for the convenience of a few of the Kew residents.

Mr. CURTIS suggested that the gardens should be opened early on Mondays during the summer season, and argued that so small a concession would not interfere with the work of the scientific staff.

SIR H. FRER said if his right hon. friend the Chancellor of the Exchequer would assent to the opening of the gardens on Mondays, he would, to a great extent, meet the wishes of those who were in favour of the motion.

The House divided. The numbers were:—

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

CAMELLIA HOUSES.

IN most gardens of considerable size there are glass houses for special purposes; as, for instance, the Rose house, the Heath house, Orangery; but seldom in private places does one meet with a house devoted to Camellias, and yet those who have seen Camellias in anything like perfection, must admit that no plants are more worthy of a structure specially devoted to them. Such houses, for example, as the Camellia house at Bicton, that at the nurseries of Messrs. Pince and Co., of Exeter; the front corridor of the Messrs. Veitch's nursery at Chelsea, or the Camellia house at the late Mr. Martin's place near Kingston, and many others, are sights to be seen, perhaps, but once, but to be remembered for a lifetime. Nor is it necessary to have a very large or lofty house for Camellias. Common lean-to greenhouses may be made to look well by furnishing their back walls, and planting them with a descending series of plants of shorter stature down to the front path. Common span-roofed houses look best with a bed of tall plants in the centre, and shorter ones in the side borders. Camellias, also, thrive admirably in large architectural houses, many of which are so heavy and semi-opaque, as to prove the graves of numbers of valuable plants of other kinds. The Camellia does admirably with less light than almost any other plants, and one of the greatest improvements that could be effected in not a few gardens, would be the clearing out of mixed collections of plants from architectural conservatories, and the furnishing of such wholly with Camellias. As evergreens they rank amongst the handsomest, while not even the Rose can excel them in richness of colour or in perfection of form. Individual plants in pots or single blossoms are extremely rich and beautiful, but housefuls of Camellias reaching to the stature of trees and spreading out to the circumference of Portugal Laurels, are magnificent beyond all other plants with the exception of Rhododendrons. And, fortunately, Camellias are much easier grown successfully out of pots than in them. With thorough drainage, and almost any proportionate mixture of peat and loam, or a bed of good peat or good loam, Camellias planted out are almost sure to succeed. The roots in pots get cramped and starved, or sodden; but, planted out, they have a free root run, increase and multiply faster, and continue in more robust health in consequence. In fact, no plants are more easily kept in health and in free-flowering condition than Camellias planted out under glass.

After flowering is the best time to prune them, if they need it; and no plants pay better for skilful treatment than these. The late Mr. James Barnes used to cut in the fine plants at Bicton rather severely every year; this kept them at home, as it is called, and caused them to break well back, so that almost every plant was a perfect specimen, clothed with foliage, branches, and flowers from base to summit. After pruning is also the most convenient time to dress with some fresh soil, if the plants seem to require it. This will not generally be oftener than once in three years, and the surface dressing should be put firmly on the old soil so as to encourage the roots up into it. Loose dressings prove injurious by concealing the state of the borders, and the roots also refuse to strike freely into them.

It is almost impossible to overwater Camellias during their growing period, provided the borders or beds are thoroughly drained, which is essential to success. Manure water may also be freely used at this stage if the plants be at all weakly; the tops should also be freely syringed at least twice a day, and, unless the house has a northern or eastern aspect, the roof should be shaded from, say, 11 till 2 o'clock during the growing period, should the weather prove bright and hot. As the growth gets nearly finished and the buds begin to show, cooler and drier treatment should be adopted until the houses are either unroofed for a month or two in July, August, or September, or

the ventilators and door must be all left open night and day. The transition from the open state to the closer one of flowering in the autumn must be made skilfully, a step, as it were, at a time; otherwise, the buds are apt to drop. The best time to plant out Camellias is in February or March, just as the plants go out of flower and are starting into fresh growth. As much of the old soil should be removed from the old balls, and as many of the roots should be unravelled, as possible. It is seldom, however, that many of the latter can be undone without wounding or breaking them; if only a few can be directed out from the ball, this will generally be all that is practicable. The soil must be placed up firmly against these, and the old balls. This is a work of some delicacy and difficulty, for unless the new soil be brought up tightly against the old balls, the water passes by, not through, the latter, and the plants may die of thirst, while the new soil is saturated with water close to the dry ball. On the other hand, the projecting roots are apt to be bruised and broken in the necessary consolidation of the soil. After planting, it is good practice to give the plants a good watering; this effects a closer union between the old roots and balls and the rich compost than any amount of mere mechanical consolidation can accomplish, and enables the roots to strike away at once into their own root runs. As there must necessarily be considerable reduction and disturbance of the roots through planting out, it is well to reduce the tops at the same time by the removal of any unshapely or unhealthy branches. By maintaining a semi-saturated atmosphere for a time, and also shading overhead, should the weather prove bright, the plants will speedily start into vigorous growth and thoroughly establish themselves in their new quarters, frequently making more growth the first season of their being planted out than they have done several years previously.

D. T. FISH.

Hardwicke House, Bury St. Edmunds.

CAMELLIAS PLANTED OUT.

WHERE there is convenience for planting out Camellias, there can be no question that they not only grow more freely than when grown in pots or tubs, but they also produce a greater quantity of flowers; yet it is not well, even where a suitable house exists for planting them out, to treat in that way more than part of the stock, for the reason that there is no means of controlling the time of flowering, either by hastening or retarding the bloom of any portion in a way that can so easily be done with plants that are movable from one structure to another; but in most gardens where there are more than a very few glass houses, space may be found to turn out some of the plants. In the case of any that have been for a considerable time in pots, it becomes necessary to some extent to disturb the ball, with a view to a partial loosening of the roots in planting. Twice in the year can this operation be performed with less interference with the growth and flowering capabilities of the plant than at other times—that is, now, before much growth has commenced, and after the season's shoot extension is completed and the buds about forming. If the disturbance of the roots, already alluded to, take place later in spring, when the principal portion of the plants are just about commencing to grow, it will check them severely; and if left until the autumn, when the buds have attained any size, it is almost certain to cause their falling off; consequently, if planting out is to take place before growth is made, there should now be no delay. The bed to be occupied by the roots ought to be of sufficient depth to admit of 6 in. of drainage material, which may consist of broken bricks, or anything of a like character, reduced to pieces 1 in. or 2 in. in diameter, over which it will be well to lay a thin turf to keep the fine particles of soil from settling down amongst the drainage, similar to the usual course followed in making a Vine border. Above this there should be depth enough to have 2 in. or 3 in. of new soil beneath the roots, and to allow the balls to be sunk 2 in. or 3 in. below the surrounding soil of the surface of the bed when rammed quite solid round the plants so turned out; this is necessary to prevent the roots getting dry, by the water, when applied, percolating through the new material in a way that would leave the ball dry; to further

prevent this, it will be well to perforate the undisturbed part of the ball with an iron skewer. It is requisite to impress the necessity of these precautions on those who may not have had experience in the planting out of Camellias, from the liability there is of the soil occupied by the roots that have not been disturbed, getting dry; when this occurs, and whilst it remains in that state, the plants can never make satisfactory growth. Turning out of the pots in this manner may, with advantage, be practised upon specimens, the branches of which have got into a thin straggling condition, as, when the roots that have thus unobstructed room to spread have attained strength, the plants will generally be found to push out quantities of young shoots from the old wood. I should, however, by no means recommend the branches being cut in, however loose and thin they are, until a season has elapsed after they have thus broken freely; for, where the unavoidable disturbance of the roots takes place, and there is a reduction of the leaf surface by pruning as well, the simultaneous check becomes so severe that plants in not over vigorous condition take a long time to recover. For back walls in lean-to or hip-roofed houses, or where there happens to be an end wall to a span-roofed house, there are few more desirable plants than Camellias, if there is root room available for planting them out. Their handsome ever-green foliage affords an agreeable covering for the walls, in addition to the flowers they produce, and the free growth that is usually made, consequent upon their extended root development, enables them to cover a considerable space in little time.

T. B.

Soil for Camellias.—It is frequently urged that Camellias require peat and other ingredients almost out of the reach of ordinary cultivators. That they will grow in peat we all know, but its quality varies so much that the majority of growers would do better when making a bed or border for them to form it as they would a Vine border, simply omitting all noxious rank manures and relying on a top spit of an old pasture to supply nourishment. This would maintain healthy growth longer than any kind of compost ever put together. A little dry cow or sheep manure or sand if the soil be deficient in that respect, might be added with advantage. If at any time the plants need stimulating, liquid manure or a rich top-dressing keeps all going on satisfactorily. This is the best season for planting Camellias, and I would recommend any one having plants in an unsatisfactory condition to plant a portion of them out-of-doors, not under the shade or drip of trees, but where they would be subjected to moderate exposure, *i.e.*, where the force of cutting winds would be moderated by trees or shrubs or buildings. Our most flourishing beds of them are on Grass in openings in the Pinetum and pleasure grounds, where dense specimen Conifers grow in luxuriance without shading them. Camellias out-of-doors, though perfectly hardy, will never supply the place of those under glass, as spring frosts are so liable to damage their flowers. Under glass they are the very best winter flowering plants which we have. Their season of flowering too may be lengthened by having plants that mature their growth early and that begin to expand their blooms before winter sets in. This a continuous succession may be maintained all through the dull months until Roses are abundant.—J. Groom.

Is it Necessary to thin Camellia Buds?—This is an important question, inasmuch as it just determines whether the grower shall have two blooms, or even more, in place of one. Thinning the buds out, when there are more than one or two, at the points of the shoots, to one only, is generally recommended and practised, on the plea that, if all were left, it would exhaust the tree, and impede the perfect development of the flowers generally. The entire wisdom of the practice I have, however, often doubted; and, when I have followed it in any instance, I must confess it has been with reluctance, and not with a conviction that I was doing much good. Consequently, I have not been very particular in lessening our supply of Camellias by robbing the plants of their buds. A fine plant of the old double white has these two years been allowed to carry as many double buds as it produced, and it shows no signs whatever of distress; and the same applies to other sorts that have been similarly treated for a considerably longer period. The old double white mentioned had hundreds of buds upon it; but if I had thinned them out to the best and largest, the most of them would have been over by this time, as they began to expand at the beginning of December. As it is, there are some hundreds of later buds to come on yet; for it is very rarely that two blooms of the double white expand at the same time on the same shoot. As soon as one is out, the next most advanced comes more quickly, and so on with the third. I doubt

if the mere act of flowering exhausts a plant in the least, though I am aware it is a theory with Chrysanthemum growers that thinning the buds of their plants makes those left grow larger. Probably however, it is the extra freedom and room which permits their full development. One never sees Vines distressed by flowering, nor yet by the swelling of the berries up to the stoning period; and then comes a sensible pause in the production of wood growth, which is less vigorous. Of course, it is well known that the energies of all plants are most taxed when they begin to form and mature their seeds. In the case of the Vine, I have never had reason to think that the plant felt the strain before the berries began to stone. Up to that point the green berries seemed to act the part of leaves, and to be agents of elaboration. And it appears to be much the same with the Camellia; if it be not permitted to produce seed, it is not very material how many flowers it is allowed to produce.—C.

Camellia Sports.—I send you two Camellias gathered from the same plant. The original plant is the *alba plena*, or double white; it has been in my possession six or eight years, and is about 4 ft. high. There has been nothing particular in the buds or flowers until last year, when I observed on one branch a flower slightly tinged with pink. This year the branch is producing blossoms of a beautiful rosy-pink, with a pale stripe in the middle of each petal. I send you a bloom, and also a white flower from the opposite side of the tree. Can you suggest any means by which I can secure a reproduction of these pink blooms? Can it be done by inarching on another tree? or would you advise cuttings being struck? I cannot decide whether this pink variety is a true sport, or whether the original stock on which the *alba plena* may have been grafted has influenced this particular branch.—W. N., Newark. [It seems to be a sport, and a very pretty one both as regards form and colour. You may secure it by inarching now on a healthy young Camellia, or you may graft it or strike cuttings of it in the autumn.—M.]

ON CROSSING THE AURICULA.

ONE most favourable evidence of the strength and intensity of the Auricula revival, is found in the activity shown by some of our cultivators in the way of producing new varieties of this glorious spring flower. Mr. G. Turner, Slough; the Rev. F. D. Horner, Kirby Malsard; Mr. B. Simonte, Sheffield; Mr. E. Pohlman, Halifax; Mr. J. Douglas, Loxford Hall; Mr. John Read, Market Rasen, and others, are working patiently and systematically in this direction, and with cheering results. In a communication received from Mr. Read the other day he gave me an interesting account of his method of crossing the Auricula, which is worthy of publication as a contribution to floricultural science. In all his crosses Mr. Read almost invariably selects two varieties of the same class, as green-edged, white-edged, grey-edged, or selfs, taking care that the flowers are at the same stage of maturity in the pip as possible, choosing the seed-bearing parent for form, and the pollen parent for colour. As soon as the pips to be operated on had partially expanded, so as to enable Mr. Read to see into the tube and notice that the anthers had not burst, he takes a pair of small-pointed scissors, and with these cuts away the pips just below the anthers, being careful not to injure the stigma with the scissors; there is then no danger either of self-fertilisation or of being crossed by insects, as they will not approach a mutilated flower. When the flowers of the pollen-bearing plant expand and the anthers are in that powdered condition suggestive of being in a state of fitness for the operation, advantage is taken of a fine sunny morning to examine the stigma of the prepared pip, which will most probably be in a fit state to receive the pollen, and will present quite a viscid appearance on the summit; a camel's-hair pencil is employed, and being first drawn to a point by placing it in the operator's mouth, it is then used to collect a portion of pollen from an anther of the flower to be used in this way, and it is then inserted in the mutilated tube, scattering the pollen on the stigma in the act, to which it will adhere, repeating the operation to make the work doubly sure; and if the day chosen for the purpose be fine and warm, the operator will soon perceive the effect produced on the stigma. If several different crosses are to be made, it will be necessary to wash off any remaining pollen from the brush after each attempt; and, remarks Mr. Read, "I merely draw the brush through my mouth for the purpose; this is my invariable practice, and it was also the practice of my late floral friend, John Cunningham, and

the raiser of John Waterson, grey edge; Mrs. Campbell, white edge; Peter Campbell, Tam O'Shanter and Souther Johnnie, green edges." When setting down the foregoing notes, Mr. Read also remarked, "I have now fine pods of seed on Headly's George Lightbody crossed with Lancashire Hero; True Briton and Earl Grosvenor crossed with my seedling Regularity; Lancashire Hero crossed with Colonel Taylor; and Pizarro crossed with Lord Lorne. From these crosses I fully expect something worth looking at." Mr. Read has very kindly sent me a few of his seedling Auriculas to flower, and also a few of his seedling gold-laced Polyanthus; of the latter he has been a grower for many years, but has parted with his named flowers, leaving himself only some seedlings from good crosses. Let us hope they will emulate in quality and usefulness some of his new Auriculas.

R. D.

FUCHSIA SPLENDENS.

This is one of the most beautiful of Fuchsias for winter flowering. It strikes readily from cuttings at all times of the year, and, in addition to its being useful for pot culture, it forms one of the best of plants for growing in baskets. It is well man-

Fuchsia splendens.

aged in Mr. Cannell's nursery at Swanley, where it is now finely in flower, and from whence sprays were furnished from which our illustration was prepared.

C. S.

FUCHSIAS IN SMALL POTS.

How seldom do we see Fuchsias grown well in private gardens in small pots, and yet they are plants well adapted for growing in that way. The pots generally selected for market Fuchsias are 5 in. ones, and the result is surprising to those who have not experienced what can be done with them under such conditions. I feel sure that if lovers of flowers generally knew how effective Fuchsias are for all decorative purposes, and how easily they may be had in bloom almost the whole year round, much more attention would be paid to their culture in small pots than is now given them. Briefly, then, I will endeavour to describe the treatment which I have found

from considerable practice to produce the best results. Let us suppose that the first batch of plants are required to bloom in perfection in March, at which time they form most beautiful objects to mix with spring flowers in the conservatory or for table decoration. The kinds which I have found best adapted for early flowering are Mrs. Marshall and War Eagle. The cuttings for this purpose should be struck in the preceding August. Their mode of propagation is so simple and well known as to need no description here. They will succeed in any close shady frame or hand-light. When sufficiently rooted, which should be in a very short time, pot them off singly into thumb pots, in a mixture of loam and leaf soil, with plenty of silver sand, replace them in a frame, and shade for a few days. After this they will bear full exposure to light and air, but be sure that they never in any way suffer from want of water, as the object in view is to secure bushy plants, with green foliage to the rim of the pot.

As soon as they have grown to the height of about 3 in. pinch off their points, which will induce them to break freely. Keep them well syringed and free from all insect pests. Washing with Tobacco water is best for the destruction of green fly, as fumigation, if ever so carefully done, is apt to cause the loss of the foliage. As soon as they are well rooted, shift again to 3 in. pots; and if a cold pit be available, with coal ashes to place them on, then this is the place of all others in which to grow them well. The lights can be moved off altogether at night in favourable weather, as they greatly enjoy the dew. When the shoots have broken well, and grown an inch or two, stop them again, so as to induce them to form compact little bushes. By the end of September they will be ready for their final shift into 5 in. pots, using, in place of leaf soil, about one-third part of decayed manure. Drain the pots well with small pieces of potsherds, and press the soil moderately firm; replace the plants in the pit, and continue the syringe on all fine warm days, with strict attention to watering, stopping, and cleanliness. About the middle of October they should be removed to their winter quarters. The best form of structure for them is a span-roofed house, with a path down the centre, and side beds with, if possible, a covering of small ballast or Cocoa-nut fibre on which to place the pots. They greatly enjoy the cool moisture arising from these and similar materials; and it also avoids too frequent a use of the watering pot. The temperature of the house should range from 50° at night to about 60° in the day, according to external circumstances. This will be a safe guide for the winter months, the object being to keep the plants growing slowly the whole time; if they once get stunted in small pots they lose their foliage, and become comparatively worthless. They should receive their final stopping at the end of December; the points of the shoots thus taken off make excellent cuttings; they strike freely in a Vinery or any house in which there is heat, and will follow the earliest plants up well, requiring treatment in all respects similar; only, as they will have the advantage of increasing daylight to grow in, they may be kept warmer; and, indeed, the quicker they are grown the finer will be both flowers and foliage.

It is well at this season to have a few old plants of the best summer-flowering varieties to put into heat, from which to obtain a supply of cuttings. After this the latter can always be obtained from the stoppings of young plants. I would also recommend a batch of cuttings to be put in, according to requirements, every month until September; by so doing a good supply of fresh blooming plants can be had from March to December. But to return to the early plants; these we will suppose are finally pinched in, and are, as they should be, bushes about 6 in. or 8 in. high from the pot. Increase the temperature with the lengthening days, and maintain a free, moist atmosphere; now a little weak manure water may be given with advantage. There is nothing whatever better for this purpose than clear, weak soot water. Be careful in ventilating to avoid all cold draughts of air; this is a fertile source of mischief to the foliage, which, if taken proper care of, is of so much beauty and importance. By the first week in February the plants will require tying into shape; this can best be done by placing one strong stick in the centre of the pot and tying the shoots to it, so as to form little pyramids. They will require frequent attention to this matter: As the bloom buds make

their appearance, manure water may be given more frequently, and they should be well washed with Tobacco water before opening their flowers, taking care to syringe well with clean, soft, warm water, next day, so that no stains may be left on the plants. On bright days shading for a few hours will be useful.

Let us suppose that we are now in March; our plants, if all has gone well, will be compact little specimens 18 in. to 2 ft. in height, and about 1 ft. through, and loaded with fine large flowers and deep green shining leaves, than which nothing can be more ornamental. All the attention which they now require is abundance of water until they fade and the younger plants take their place, when the old ones can be thrown away, or, if desired, a few can be kept to form large specimens. With the culture of these last-named, however, I do not intend to deal; my object is simply to direct attention to the merits of the plant as a quickly-grown object of great beauty in small pots, and withal so easy to manage as to be within the means of everybody. I do not give a list of varieties, as almost all the really good kinds are amenable to one system of treatment. I may, however, add that kinds having the stiff, branching habit of *Lady Heytesbury* do best without stopping, as they form naturally a well-furnished plant, of course with the support of one stake. The two early kinds which I have named are the best for late autumn as well as spring work. In conclusion, I will say that I feel sure, if the few simple rules which I have given for the growth of small specimens of this charming plant be carried out, the result cannot fail to give much gratification to the grower.

H. BAILEY.

GROWING PLANTS IN FRUIT HOUSES.

ALLOW me to state, in compliance with "M. F.'s" request (p. 190), how I manage to have *Linum trigynum*, *Sericographis Ghiesbreghtiana*, and *Schizanthus papilionaceus* in full flower during the winter. We start with a few of the *Linum* in the spring by shortening all the shoots back as soon as the plants have done blooming, after which they are placed in any forcing house or pit where they can get a little moist heat to give them a start, with a view to supplying us with a sufficiency of cuttings. These are taken off with a heel, that is, with a portion of the old bark at the base, when they are about 3 in. long, and are then inserted in sandy soil and placed either under a bell glass or in a propagating box where there is plenty of atmospheric moisture till they strike root. This they do in the course of a fortnight or three weeks, when they are ready for potting, which is done in soil consisting principally of loose fibry peat or leaf mould, *Linums* being plants that like vegetable matter in which they can ramify freely. When potted off they are replaced in a similar situation to that which they had before the cuttings are taken till they push again, which brings them to the end of May or the beginning of June, and after that they go into any cold frame or pit that happens to be at liberty, to be kept therein and grown on during the summer. To keep them clean and healthy during that season I always make a point of having some kind of plunging material such as half-decomposed leaves or tan that I can put the pots in, thus keeping an equable degree of moisture about the roots. The heavy syringings they receive keep the air moist, the object being to keep them free from red spider, their great enemy—a difficult task to manage when treated in any other way. Isolated as we have them, and under so much control, it is very rare that the above-named pest puts in an appearance, but should it do so at any time we at once resort to sulphur, which we first mix as a paste and then stir it up in some water kept agitated while syringing it on. To be effectual, however, the under and upper sides of the leaves must both be thoroughly wetted, and the frame shut up early every afternoon, so as to raise the temperature to nearly 90°; before doing which the walls and other surfaces should be wetted, that the air may be saturated with moisture. This treatment continued for a week or so generally has the desired effect, and the sulphur is then washed off by giving a good drenching, either by means of the garden engine or syringe, and after this is done, the latter instrument is used freely every day both morning and evening, before opening or shutting them up.

This regular and continuous wetting of the foliage is the main secret of success in growing fine healthy *Linums*, for do what one will, without it it is impossible to have them in the condition they should be. In the majority of cases, under different treatment, they become partly defoliated, showing gaunt, bare stems, and what few leaves they have towards the tops of the shoots are invariably discoloured, giving the whole plant a wretched, woe-begone appearance. Besides being such moisture-loving subjects, both at the roots and top when growing freely, with the heat they get by shutting them up early during the summer, they also require shade during the heat of the day, which should be afforded by drawing a piece of tiffany, canvas, or any thin, light material of that kind over the frame, removing the same at the time of closing, or whenever the sun goes in, so as to keep the foliage as stout in texture as possible. The greater part of our plants are in 6-in. and 8-in. pots, a size quite large enough to grow fine specimens with the help of a little weak manure water given towards the autumn, and afterwards when carrying their bloom. If we wish for a few large bushes, we obtain them by keeping some of the best and most shapely of those cut back, which are potted on and treated in the same way as the others. The habit of *Linums* is naturally shrubby, but, in order to make them more shapely, it is sometimes necessary to stop the leading shoots, which causes them to break again and keep well furnished below. In potting, we give free drainage, and use soil composed of either refuse, peat, or leaf-mould and fibry loam in the proportion of about two parts of the first named to one part of the latter, with just a sufficiency of sand to keep the whole open and porous. By the end of September or early in October they are removed to a house, and, during winter, kept in a temperature never lower than about 45°, in which they unfold their flowers in the greatest profusion.

As regards the *Schizanthus papilionaceus*, the seed for winter blooming is sown in August, and the plants pricked off and grown on, three in a 6-in. pot, in any cold frame till late in the autumn, when they are placed on any light, airy shelf near the glass till they begin to show blossom. This prevents them from becoming drawn up, to which, in the absence of sun they have a strong tendency. Like all, or most annuals, they are fond of rich soil, and succeed best in that which is light, if potted somewhat firmly, and with good drainage bear liquid manure and plenty of water, after they become fully established. To have plants to come in at this season or a little earlier, it is necessary to sow again at the end of September, and grow the same on in slight heat till forward enough for the greenhouse, in which they stand well in a temperature anywhere about 50°. There is another annual I can specially recommend, that is most valuable for cutting to work up in choice bouquets or embellish vases, as it is not only lasting but is very choice and suitable in size and colour, the individual blooms having much the shape and appearance of those of the *Forget-me-not*, and having a deeper blue shade that is very telling when associated with those of a paler hue. The name of the plant just referred to is *Browallia elata*, and there is a larger variety, *B. Roezli*, that is even more desirable, both of which require the same treatment as that recommended for the *Schizanthus*, when, if so favoured, they will be found to keep up quite a display for several months in succession.

In propagating the *Sericographis Ghiesbreghtiana* we always make choice of the tips of the shoots taken from the old plants before cutting them down, as, being shorter-jointed than others that form afterwards, they make the closest and best specimens. At this time of year the tender young points are very liable to green fly, and therefore, previous to putting the cuttings in, they should be examined, and if found to be infested with these parasites, dipped in Tobacco water, otherwise the leaves get criddled just as they begin to unfold. Any hotbed or close place where a *Verbena* will strike suits the *Sericographis*, as it is remarkably free rooting, and when potted off does well for a time on the shelves of a Vinery or Peach house till the weather becomes warm enough for growing it on in cold frames. This is generally the case early in June, after which, if plunged in a bed of leaves and tan, and kept duly watered and syringed before closing, their growth is rapid and the shoots of that firm character that always produces a great

quantity of bloom. Except on sunny days, and during just the height of summer plants of *Sericographis* do not require shade, unless after being repotted or disturbed at the roots, when, if they show symptoms of flagging, it will be advisable to screen them for an hour or two till they again get a fair start. Although they grow in almost anything, sandy peat suits them best, but failing this, leaf-soil and loam answer very well, used in about the proportion of two-thirds of the former to one of the latter, in which they require to be potted somewhat firmly. The best place in which to winter the plants till they come into flower is an intermediate house, where they can be placed so as to have plenty of light, and the full benefit of all the sun we then get, which helps to colour the bloom, and adds to its texture and substance. When removed to the lower temperature of the greenhouse, it is important that the plants be kept as dry at the roots as they will stand without suffering, for, although they will bear a good deal of hardship, cold and wet are very trying, and apt to cause the flowers to fall. In case of mealy bug assailing them, we lay the pots on their sides, and syringe the shoots and leaves with paraffin and water, using a wine-glass of the former in a four-gallon pot. This remedy is much easier and far more effectual than hand-washing, for however carefully that may be done, it is never thorough in its cleansing, being sure to leave some for stock. S. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Pink Lady Blanche.—This is a free-blooming Pink, and one very valuable for forcing; it is easily grown and useful in the conservatory, as well as for cutting for bouquets, white flowers being always in request. The blooms, too, do not burst like those of other varieties. My mode of culture is as follows: About the end of the present month, or as soon as there are plenty of cuttings, which there will be if the plants have been forced on in a little heat, I insert them in the same way as I do those of *Verbenas*; I plunge the pots in a gentle bottom heat under a hand-light, or place a square of glass over the pot, shading them when the sun is very powerful; when well rooted, I gradually harden them off. About the end of April I plant them out about 10 in. apart in good soil, and if it contains 2 in. or 3 in. of loam, all the better; during the summer they will take care of themselves. About the middle of October they will require to be potted in 5 in. pots, and kept in a cold frame through the winter, or till they are required for forcing.—W. G.

Oak-leaf and other Pelargoniums.—I have the Fair Helen, Oak-leaved glutinous sort, Lemon and Citron (I think it is) scented, also another scented like camphor or something of that character.—M. GILLUM, *Red House, East Moulsey.*

Ivy-leaved Pelargoniums.—There is now such a diversity in the colours and character of the Ivy-leaved Pelargoniums that cultivators of all classes will increase the attractiveness of their conservatories by giving them more attention. For filling baskets and trailing over the edges of vases, rustic and otherwise, they possess merits of a high order, and these merits are generally recognised; but their value for specimen culture, and for decorative purposes in semi-specimen form, does not appear to be sufficiently known. Specimens of the Ivy-leaved varieties are exceedingly attractive, and their production is very simple, as you have only to put them in 8 in. pots, three thrifty examples in each, and then train the shoots to a neat trellis of wire, or neat stakes. Well draining the pots, by placing about 2 in. of potsherds in the bottom, may be regarded as a matter of course, and the plants must be placed at regular distances apart, with just sufficient soil underneath to raise the surface of the ball to within about 1 in. of the rim. The next step will be to fill the space between the balls with the prepared compost, and to be careful to press it somewhat firmly. The trellises should be securely fixed in their places when the potting is completed, so that the training may be done immediately afterwards. Balloon or barrel-shaped trellises are perhaps the best, and they ought not to be too large, as it is most important they should be well covered. Those 2 ft. high and 18 in. in diameter, or thereabouts, will be the most suitable. For decorative purposes they should be grown in 6 in. pots, one plant in each, and trained to a single stake. When loosely trained in this way, with the lateral growth hanging down in a natural manner, they are surprisingly beautiful. The stakes, it may be added, should be about 18 in. in height. All the varieties are more or less suitable for culture as here recommended, but those who do not want a large number will not wisely if they select *Lucie Lemoine*, *La Fiancée*, *König Albert*, *Progress*, *Argus*, and *Bridal Wreath*.—"Gardeners Magazine."

TREES, SHRUBS & WOODLANDS.

A FEW GOOD WEEPING TREES.

GREAT attention is paid to the propagation and training of trees of a weeping character in the United States of America and also in Canada, and more particularly in the province of Ontario. One of the most extensively cultivated is the Weeping Birch, sometimes called the Lady Birch. This tree has a very light-coloured bark, and graceful branches, which are swayed to and fro by the slightest breeze. It was introduced into the province by Messrs. Ellwanger and Barry, in the year 1851. Its home appears to have been in Germany, for a correspondent of the "*Horticulturist*," writing from thence in 1845, speaks as follows concerning a specimen which he had seen in Booth's nursery at Holstein:—"It had descending shoots 32 ft. long. The branches hung as perpendicularly as those of the Weeping Sophora, or the common Weeping Willow, and they are quite as delicate and pensive as the latter." Once introduced, this tree was eagerly sought after, and in a very short time from 5,000 to 15,000 stocks were budded with it annually. The original tree was cut down only last November, to make room for improvements. The projectors of the fine park at Chicago, have planted one of their finest avenues with this tree. The Out-leaved Birch is in Ontario planted in the most prominent and conspicuous positions upon lawns. It is a rapid grower, and attains a very considerable size. For avenue planting it is preferred to all other trees, and it has been extensively used for this purpose in western New York. Young's Weeping Birch was raised at Godalming. To the graceful elegance of the Birch family, it adds the erratic habit of the Weeping Beech. Its long, slender branchlets fall from the main branches in thread-like spray.

The Kilmarnock Weeping Willow was introduced into Ontario in 1857. It was first discovered growing wild in a sequestered corner of Monkwood Estate, near Ayr, in the west of Scotland. This Willow is well adapted for small lawns, and for such it is often grafted on stocks from 6 ft. to 8 ft. high. Though comparatively little cultivated in its native country it is highly esteemed in America.

The Weeping Beech is one of the most remarkable of drooping trees, as its branches first shoot upwards then outwards, twist and turn in a variety of shapes, and finally droop and trail on the ground. It is one of the largest of lawn trees, and in Ontario some specimens cover an area of 100 ft. in diameter. One of the first specimens known grew in the garden of the Baron de Man, at Brussels, and a noble specimen was to be seen in the nurseries of Mr. Anthony Waterer, at Woking.

The White-leaved Weeping Linden is a handsome drooping variety with large round leaves of a greyish-green colour above and a silvery-grey beneath. When worked upon stocks of standard height the branches first shoot out horizontally, and then bend gracefully towards the ground. Its distinct silvery foliage makes a fine contrast with the deep green of surrounding trees.

Of Weeping Elms the country possesses many varieties. Prominent among these is the American Elm, a noble and stately tree. The Camperdown is a very picturesque and elegant variety; its growth is strong and its branches often assume a zigzag form outwards and downwards; the leaves are large, dark green, and glossy, and cover the tree with a luxuriant mass of verdure. The Scotch Weeping Elm is also extensively cultivated, but it does not equal the last-named.

The Weeping Mountain Ash has probably received as much attention as any weeping tree, on account of its distinct and curious habit when worked 2 ft. or 3 ft. from the ground and allowed to grow wild. In the autumn when it is laden with large clusters of bright red fruit it produces a brilliant effect.

The Weeping Poplar is not so elegant as some of the drooping trees noticed above, but its character is decidedly pendulous, and its branches spread and droop gracefully. As it is a rapid grower, it is well calculated to produce immediate effects in situations where such trees are desirable.

The appropriate position for these trees is always upon the open lawn, single, never in groups or masses, nor mixed up with other trees in belts or borders. In the hands of a skilful planter they are capable of producing the most charming

results, and are more effective in giving character and expression to a landscape than any other trees. A. J. BURROWS.

SHRUBS FOR SMALL GARDENS.

Now that frost may soon be expected to relax its hold and better weather set in to dry and improve the condition of the ground, it is high time to be looking round to see what mischief the severe winter has wrought among evergreens and ornamental plants with the view of taking the first opportunity to set about repairing the damage. Where Hollies have to be planted, in trenching or digging holes for them or other shrubs of a like character, some thoroughly decomposed manure worked in with the soil will be found a great help, not only in expediting their growth, but in inducing finer leaves in the case of the variegated kinds. Next to Hollies come the Aucubas, which, since the male variety has been introduced, have been greatly improved. To get them to bear berries freely, it is only necessary to plant a male plant near, in order that the bees or other insects may carry the pollen from one to the other when searching for the rich nectar which the flowers contain. Except the Eucunymus, I know of no shrub that will bear smoke and dust better than the Aucuba, and this makes it of great value for planting in the vicinity of towns. The same may be said of the Eucunymus, the habit of which is close and bushy, and the plant altogether well suited for a limited space. Palms are everybody's favourites, and were it only known how hardy *Chamærops humilis* is, I am sure it would be in great request for the embellishment of forecourt gardens and planting on lawns, as, when it attains a little size and age, it is a noble-looking object, and a great ornament in any place. As to its power of withstanding intense frost and cold, the severe time through which we have just passed has tested its capabilities in this respect, and, although quite unprotected and fully exposed, I cannot see that the one which we have here has sustained the least harm, nor do I hear of any others elsewhere having suffered. Another fine-leafed plant is *Berberis nepalensis*, which has magnificent Palm-like leaves of great size and of a deep, glossy green colour. In form it greatly resembles the old and well-known *B. Aquifolium*, but it is considerably larger and more upright in growth, and when in flower or bearing fruit in such clusters as it usually does, it is one of the most effective evergreens that can be had.

For affording variety and breaking up uniformity, nothing comes in better than the Bamboos, the hardest of which is *Bambusa Metake*, a variety introduced many years ago from Japan. This, during the present winter, has retained its foliage and is quite unharmed, but *Arundinaria fastata*, the most elegant of all, is leafless, although the stems appear as if they would become refurnished in the spring. To group or associate with these, *Arundo conspicua*, *A. Donax*, and the Pampas Grass, are the most suitable, any, or all of which brought into juxtaposition, produce a striking effect. The whole of these like a loose, open soil, with plenty of water during the summer and autumn, when growth is active, or the *Arundo* and Pampas are about throwing up their fine plume-like flowers. *Aralia Sieboldii* is, likewise, found to be sufficiently hardy to withstand ordinary winters, and is a plant of noble aspect and one that should not be lost sight of, as it is thoroughly deserving a place wherever room is available. The leaves of this fine *Aralia* are much larger than those of the Fig, and are deeply cut or divided, and being so bright and polished looking, are exceedingly ornamental. After a few years' growth, and when fully established, it sends up huge panicles of flowers greatly resembling those of the Ivy, as do also the berries that it bears afterwards, from which young plants may be readily raised. *Garrya elliptica*, when clothed with its long, drooping inflorescence, is an object of great beauty. The flowers are borne at the ends of the young shoots formed during the previous year, and have much the appearance of the catkins of the Hazel, but are considerably longer and more ornamental. Then again, there are *Rhododendrons*, the most beautiful and hardy of all flowering shrubs, that only require to be planted in peat or sharp, gritty soil, and supplied with plenty of water to succeed perfectly. *Berberis Darwini* and *B. stenophylla* are remarkably handsome when laden with their rich gold and bronze-coloured bloom, and both are plants specially adapted for small gardens, as they may be pruned and kept to any size required. Among deciduous kinds, *Cydonia japonica*, *Deutzia crenata*, fl.-pl., *Philadelphus grandiflorus*, and the double Almonds and Cherries, are the most striking, to which should be added the lovely variegated *Acer fraxinifolium*, that shows up so well against dark evergreens. If space admits of planting a few upright-growing trees, *Cupressus Lawsoniana* will be found to be one of the most suitable, as it is of moderate stature and of a graceful, drooping habit which improves with age. Of smaller size, but fit associates for this come the *Retinosporas*, which equal in beauty some of the finest Ferns. All these are particularly suitable for nearly

dressed grounds where really choice plants are required, as are also the Gold and Silver Yews, which, when making their young growth, are particularly bright and cheerful looking, and at a distance appear as if covered with bloom.

If instead of the heterogeneous mass of things one generally sees crowded into small gardens and pleasure grounds, such choice plants as the above were selected, how much better would be the effect produced, as then each might be so placed as to have proper room in which to develop itself, and show off its natural beauty to advantage. There is no time more favourable for a general overhauling and re-arranging of evergreens than the end of March and beginning of April, as then if carefully lifted with good balls and plenty of root they are sure to grow, whereas those interfered with in the autumn have the winter and cold cutting winds to contend against, under which they frequently succumb. The only drawback to spring planting is, that it has to be done quickly, as at that season the buds soon burst, and it does not do to have the plants long out of the ground after the young shoots begin to show themselves. Caught just before this, the top and bottom start away together, and with a little mulching and a few good waterings, shrubs of whatever kind become quickly established. S. D.

A FEW CALIFORNIAN WILLOWS.

SOME years ago Prof. Asa Gray, the veteran botanist of the United States, gathered up all the Willows of his Herbarium at Harvard University, and sent them to Mr. S. Bobb, of Illinois, who had a Willow garden—a "*Salicetum*," as he scientifically called it. Mr. Bobb was making a study of the Salices, and had plants from many parts of the world. American botanists began to rejoice that at last a competent man would do a good service to botany, and make himself a well-deserved reputation in a difficult field. I was applied to for Californian species; that was more than six years ago. I made a pretty careful study of the Willows of Santa Cruz, and will give the readers of "The Horticulturist" the result of our work, so far as this locality is concerned. I fear Mr. Bobb has become discouraged. The task of arranging American species in a satisfactory manner is as yet unaccomplished. The Willows are the "black sheep" of the botanist, and to be successful they must be studied at all seasons of growth. Herbarium specimens will not do, unless selected as but few collectors ever select them. It is necessary to have the flowers, staminate and pistillate, in their different stages of growth. These are borne on different trees, giving the trees quite a different aspect during the flowering and fruiting season. Then the leaves should show different stages of growth, and the different ages of the plant make quite a change in the appearance of the leaf, so that leaves from young trees and old trees of the same species must be compared. Then, after the botanist has all these, still he may be confused unless he has the growing plants before his eyes. Mr. Bobb's plan of a Willow garden was therefore a good one. I tried to encourage the starting of one at our university, and sent about fifty species for trial. Nearly all have perished between squirrels, drought, and want of proper care and place to rear them. But the Willow is a beautiful tree, and many species are quite ornamental; their uses are numerous and valuable; they are easy of cultivation, and yet we know less about them than almost any other tree. There is no garden in America, except Mr. Bobb's, where they can be studied and compared. Kew Herbarium is the only place where American types of the Willow can be found. In California we have some very handsome indigenous Willows. Growing in the vicinity of Santa Cruz we have five species, as follows:

1. *Salix Bigelowii* (Torr.).—Bigelow's Willow, the commonest species in California, grows from 10 ft. to 50 ft. high, generally along streams and river bottoms. Leaves spatulate, glossy green on top, pale glaucous underneath, sparingly toothed on the edges, with the margin wavy. The young branches make good baskets. It flowers from January to June. It does not correspond well with Bigelow's Willow, but for the present must bear that name.

2. *S. lasiandra* (Benth.).—This, in thrifty trees, has long, tapering leaves, nearly the same shade of green on both sides, evenly and sharply serrate. It is found in the same localities with No. 1. In somewhat impoverished trees it has long, slender branches and drooping, somewhat like the Weeping Willow. It has several names—*S. lucida*, *S. pentanota*, and a number of varieties. Corresponds with the Shining Willow of the Atlantic States.

3. *S. laevigata* (Bebb).—This seems to be a new species, and a beautiful Willow too. The leaves are smooth and shining, finely serrated with sharp point, not tapering, glaucous underneath, beautifully veined. The tree grows from 10 ft. to 50 ft. high, with a pyramidal aspect when young. It resembles a cherry tree somewhat. The flowers (catkins) are pale yellow, long and slender; it blooms in

June, and the flowers remain on the tree for two or three months. Found with Nos. 1 and 2.

4. *S. sitchensis* (Bongard).—This is the Sitka Willow, found sparingly at Santa Cruz, perhaps its southern limit. It is beautifully lined with white velvet on the under sides of the leaves—the upper sides are dark green, evenly veined, with scarcely a trace of velvet except on the midrib. The tree, from 5 ft. to 15 ft. high, has a reclining aspect, and grows in wet places near the edge of and bending over streams. Over the bay at Monterey is found *S. Coulteri* which resembles the Sitka willow in the velvet appearance of its leaves, but it is a different species, and very pretty.

5. *S. brachystachys* (Benth.).—A very interesting little tree on our brushy hill and mountain side, seldom coming down to the bottom lands. In February the male flowers light up the hill sides with their short woolly catkins, in a glow of white splendour; but the female flowers, larger and coarser, do not appear until late in May. The leaves are in shape like those of *S. Bigelowi*, but are lined underneath with a thin coat of fine hairs which turn rusty brown as they become old.

When the second volume of our Californian Botany is published we hope, through the perseverance of Mr. Bebb and others, to see the Willows of our State brought into a more satisfactory system, so that our local botanists and horticulturists may understand each other better when talking of this useful and beautiful genus of plants. —DR. ANDERSON, in "Californian Horticulturist."

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Polygonum virginianum.—This is one of our most beautiful summer flowering shrubs, if I may so call it, for it is cut down to the ground like a *Phlox* in winter, but it grows quickly into the form of a shrub in summer, and produces shoots from 6 ft. to 10 ft. long, which are completely covered the whole of that length with little pendant clusters of cream-coloured Spiræa-like flowers. It is a useful show plant, and one which should be planted in all shrubberies.—CAMBRIAN.

Seedling Cork Trees.—Although the Cork tree "does not, as a rule produce many good Acorms, yet, in favourable seasons, we get a few for planting, and some of the young plants are now attaining considerable dimensions. In their young state they require attention in the way of stopping strong side shoots that are rivaling the leader, for, if left to their own habit of growth they appear more inclined to form a spreading many-headed bush than a fine single trunk. The beauty of many a specimen is marred through lack of a little judicious pruning during the early stage of growth.—J. GROOM.

The Royal Forests.—There has been a good deal said lately about the way in which Dulwich College, Wellington College, and the Royal Patriotic Fund are managed, but the strongest charges brought against the administrators of these funds fade into insignificance by the side of the returns given in the "Financial Reform Almanack" with regard to the "Royal Forests and Woodlands," which show that, extensive and valuable as these properties are, they are anything but profitable to the public:—Dean Forest: Receipts, £8,814; expenditure, £6,720; cost per cent. for management, 276. New Forest: Receipts, £11,909; expenditure, £9,986; cost per cent. for management, £83. Windsor Park and Woods: Receipts, £5,977; expenditure, £26,968; cost per cent. for management, about four-and-a-half times more than the receipts.—"Truth."

The Climbing Hydrangea (*Schizophragma hydrangeoides*).—Considerable expectations have arisen concerning this new climber. Possibly, also, these expectations have been exaggerated by incorrect reference to the charms of *Hydrangea paniculata grandiflora*, charms that have dimmed by comparison the beauties of other *Hydrangeas*. The conception of a Climbing *Hydrangea*, with great white or pink flower trusses 18 in. long enveloping the front of a building, rather startles the imagination. But the correct statement that the plant in question has a poorer truss, with sterile flowers less showy than those of *H. paniculata grandiflora*, should moderate any excessive expectations. After all, we know of no one who has flowered the Climbing *Hydrangea* in America, and certainly, in other respects, our knowledge of its behaviour is small. Seed has been imported within a few years, for the first time from Japan, and a few plants exist. We have some small plants ourselves, and Messrs. W. S. Clark, C. S. Sargeant, and P. Henderson have others. It seems to us premature, therefore, to decide as yet on its merits. The foliage is attractive, and, judging from descriptions of eye-witnesses of its beauty in Japan when in bloom, its value must be considerable. With us it grows slowly at first, like the *Wistaria*, until it obtains

well-established strong roots, when its development is rapid. Its propagation from seeds or cuttings is easy, and it seems, after the trial of several years, to be perfectly hardy. Mr. Peter Henderson has a variety that differs somewhat from ours in habit and growth of leaf, but it is doubtless the same thing, showing merely the ordinary tendency to vary. Although it is too soon to give an opinion concerning the value of this climber, I feel confident that it will yet prove a fine ornamental flowering vine for America. Our need, moreover, for more good hardy flowering climbers has been frequently felt and expressed.—"Rural New Yorker."

THE FRUIT GARDEN.

FRUIT CULTURE FOR MARKET.

ALLOW me to inform Mr. Burbidge (p. 215), that hardy fruit culture, even here in Kent, is not that "El Dorado" of wealth for the growers that consumers might imagine, and it is no stretch of imagination to suppose that vast quantities of fruit are spoiled in this neighbourhood in plentiful seasons, simply because it cannot be got with profit from the growers to the consumers. In order to illustrate my meaning more fully, I may state that last summer Apples of the poorest description were selling for more per peck in Suffolk, than Kentish growers were getting per bushel from the London market; really first-class Keswick Codlings fetched only 2s. per bushel, and of this 1s. was paid for carriage and other market expenses. It will therefore be seen that no great margin is left for labour, rent, and profit. If the consumer benefited by such low prices there would be less to regret, but the general public only get a fractional advantage, as they pay nearly as much in plentiful fruit seasons as in those in which there is a scarcity. I may remark, that it is not from a lack of knowledge of their business that growers fail to make fortunes from fruit growing, as no class of men so closely study the fluctuations of the market. But the Plum crop is a precarious one, and any soft kind that keeps only a few days after it is ripe, is almost sure to glut the market, and in this respect Damsons pay about the best of any Plum crop. I may remark that some of the freest bearing Apples, as Lord Suffield and Cellini, although so well suited for private gardens are not good for market, as, being too soft and light, they bruise easily, and being retained by weight do not suit the hawkers.

Linton Park, Maidstone.

J. GROOM.

I WILL confine my answer to Mr. Burbidge (p. 215) chiefly to his own writings on this subject. I stated that "in a plentiful year hundreds of bushels of good Plums, Apples, and similar fruits are allowed to rot because the market is so well supplied from abroad that they would not pay for the gathering." This statement Mr. Burbidge confirms in his writings on "Fruit Culture for Market," where he says "the market salesmen also foster the introduction of foreign fruit, because it enables them to be, to a great extent, independent of the fruit grower here at home, and hence he is obliged to take low prices for all but the very best of his produce. Many of the market gardeners near London left tons of Plums to fall and rot on the ground in 1875, because the market was glutted with foreign fruit, and the prices offered would not pay for picking and carriage, and since it has been the case with Strawberries." I did not infer that early Plums were a failure generally, but that they often are is indisputable. Neither did I infer that late Plums are not now grown to some extent, but the produce of the few growers mentioned by Mr. Burbidge is like a drop in the ocean, and as late Plums, according to Mr. Burbidge's saying, pay so well, that it is so much in favour of my statement, viz., that "if late Plums, to come in after the bulk of the foreign produce was over, were grown, there would be a good chance of profit arising from their culture." Albeit, I may add that in some years "even the finest fruits have failed to realise 6s. per sieve," a very low rate indeed. There is always a ready sale for fruit at a price, and there are hundreds of tons more fruit consumed now than formerly, on account of the produce supplied by the foreigner, who sends shiploads at a time to our markets, which is sold by auction for what it will fetch, greatly to the disadvantage of the home grower, should he send his produce to market at the same time. We have no proof that the foreign grower always exports his fruit at a profit; but, that he can grow it cheaper is certain; on this point your correspondent remarks:—"The American fruit grower, who obtains 400 bushels of fruit every other year for twenty years from his rich cheap soil, without manure, and with a minimum of labour and cost, can easily compete with the English grower who pays an annual rent equal to the whole purchase money of his competitor's land, and has to spend fully as much more in manure and labour; but, if the Western grower should, by fertilising his land, double its yield, the extra 400 would not be grown at a profit." This clearly shows that when a glut

of foreign fruit comes in the home grower stands no chance of profit whatever; and, if Mr. Burbidge claims great superiority for English-grown fruit, I would refer him to a statement made by himself, viz., "the American fruits that cross the Atlantic, and that have perhaps travelled hundreds of miles to or from port, look nearly as free from blemish as those of home growth." Then, as regards meat *versus* fruit culture, I still say that the calculation referred to by Mr. Burbidge fails to fairly represent the case, for whilst I am well aware that considerably more than \$100 worth of fruit and vegetables could be obtained from two acres of land in three years, even under ordinary management, I consider that the difference in the capital and labour required to cultivate two acres of land for three years and that of utilising the same space for meat culture is so great that the only way to arrive at anything like a satisfactory statement would be to invest a stated capital in the culture of the two, and judge by the profits at the end of the term.

C. W. S.

THATCHING VINE BORDERS EARLY IN AUTUMN.

COVERING Vine borders with a deep layer of dry leaves and thatching all over thickly with Wheat straw has been recommended by those who object to fermenting materials as a plan by which we may "retain the accumulated heat of summer" in a Vine border, provided the border be covered early in the autumn. One eminent Grape grower, who shares these views, has produced authorities to show that a border, covered with 18 in. of dry Wheat straw early in autumn will retain the accumulated summer heat in the border well through the winter. Now it follows that if a border covered by non-conducting materials at the end of the summer retains the heat throughout the winter, the temperature of the roots of the Vines during September, October, and November may be very much in advance of that to which the tops are subjected, 20°, we should say, at least, and, as all know who have to do with early forcing, it is the practice to keep Vines that have to be started in November or December as cool as possible during the autumn months, in order to keep the buds from pushing before their time. I have myself no objection to the thatching plan, except that I think it is an unwise practice to keep the tops cool and the roots warm at a season when it is of the utmost importance that both should have complete rest. One danger to be apprehended with Vines that have been forced early for a few years is the premature breaking of the permanent buds, which frequently occurs, and is only too much facilitated by keeping the roots warmer than they ought to be. It is obvious at all events, I think, that covering the borders early in autumn to retain the solar heat is a practice totally inconsistent with the theory that the roots should not be subjected to a temperature in advance of the tops. Has this aspect of the question presented itself to those who hold this theory on the one hand and advocate the early covering of Vine borders on the other.

Wortley.

J. SIMPSON.

POT VINES.

"A. D." (p. 216) says that injury from exposure in the case of pot Vines depends upon the way in which they have been grown. This is far from the fact. Grow Vines in pots as well as the best of treatment can produce them, and allow the pots to stand upright out-of-doors through a wet autumn and the early part of winter, and the roots will be pretty certain to be found rotten even if frost has not reached them. "A. D." confuses the preparatory growth of pot Vines with their forcing. Cultivators understand forcing to mean the treatment to which they are submitted on the season in which they produce fruit, let this be with canes from eyes or from cut backs. "A. D." speaks of some nurseries in which pot Vines are not subjected to more heat than is necessary to start the eyes. This will do for such as are required for permanent planting, but what about the quantities grown to sell for forcing? Treated in this way they would scarcely have shed their leaves in the autumn before the new ones were required to be on them. As to the assertion that pot Vines should never be exposed to the open air, if "A. D." will visit in August or September Messrs. Osborn's nursery at Fulham, he will see standing out-of-doors in rows on the sunny side of, and resting against moderately low, closely-clipped hedges, such quantities of short-jointed canes, as thick as a man's thumb, already brown and as hard as whalebone, yet still carrying their leaves green and healthy, as will show the mistake under which he labours respecting pot Vines. That immense numbers of Vines of this description are injured by being out-of-doors with their roots in a position to suffer from the wet and cold, most people are aware, and, for this reason, whenever I have had occasion to purchase Vines, if there was any probability of their having been injured, I have always examined the state of their roots. Even for planting, whether this is done whilst they are dormant or after growth

has commenced, it is well known how Vines that have all their roots alive and healthy make headway over others that have been damaged.

T. BAINES.

TWO EARLY APPLES.

AMONGST the many early dessert Apples, there are, perhaps, none better known, and few more relished or of higher merit, than the Oslin. More especially is this so in Scotland, which seems to be its adopted home, for there its qualities are superior even to what we find them in the south, where, however, it is also much prized. The Oslin is a very old Apple, and one of a very distinct character, which can scarcely be confounded with any other. There is no very authentic record of its origin, but it is supposed to have been introduced by the monks of Arbroath from France; and this is very likely to have been the case; still, it is strange that no trace of this name or of this Apple can be found in any French list of fruits. Like most good fruits, the Oslin enjoys many synonyms; amongst others, it is often called Arbroath Oslin, Arbroath Pippin, Scotch Oslin, Summer Oslin, Mother's Apple, Burr-knot, Orgion, Orgeline, &c. The fruit may be described as of medium size, flatish or roundish-oblate in shape, very evenly and regularly formed; eye large, open, prominent; stalk short and inserted in a slight cavity; skin rather thick, pale yellow, and strewn with brown dots; flesh yellowish, firm, very rich and sprightly in flavour. In warm seasons it is apt to be somewhat dry, and at other times it is liable to crack, often to a great degree. In use during September. The tree is of free growth, of erect habit, with large, broad leaves, somewhat liable to canker as it grows old, and the branches are frequently covered with knobs or burrs, from which roots are readily formed, on their being placed in the ground.

Early Julien.—This is a very excellent early Apple, generally relegated to the kitchen; but it is really a very good dessert fruit. It is not quite so captivating in appearance as many others, but in quality it is unique. The peculiar brisk aromatic flavour of the flesh, and its crisp freshness, render it extremely pleasant on a warm day in August, when juicy fruits are scarce. In the "Fruit Manual" it is compared to the Hawthornden for all its good qualities, and indeed it might be called a summer form of that variety. The fruit is of medium size, roundish and somewhat angular. Skin smooth, pale yellow, having frequently a tinge of orange on the side next the sun, and strewn with whitish dots. Eye large, the segments broad, closed, set in an irregular basin. Stalk short, set in a deep cavity. Flesh yellowish-white, crisp, juicy, brisk, and pleasant. It comes into use early in August, and is much esteemed for cooking. The tree is a free grower, and succeeds well on the Paradise stock as a dwarf. —"Florist."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Damsons, being in most seasons remunerative, are being now largely planted in Kent and elsewhere. Every year most of the orchard hedgerows near Maidstone are planted with them, and in some cases two or three rows of them are planted as wind screens for tenderer fruits. The Crittendale Damson raised in this neighbourhood is held in high estimation. Plums, when good, glut the market, and prices go so low as not to pay for the gathering; but Damsons coming in when other soft perishable fruit is over always sell well, and in some seasons realise a good profit.—J. G., *Linton*.

Old v. New Melon Seeds.—At a meeting of the Botanical Society of France, M. Duchartre called attention to a statement of M. Cazzuola in the bulletin of the Tescan Horticultural Society in 1877, to the effect that Melons raised from fresh seed bear a large proportion of male flowers and very few female flowers, while, on the other hand, seedlings raised from old seed bear many more female flowers than male. The statement was confirmed by M. Millet, a French grower, and, we may add, by the experience of Melon growers in this country.

Crab Apples.—The value of Crabs was thoroughly discussed at a recent meeting of the Maine Pomological Society, and they were generally denounced in emphatic terms. When, some years ago, they were introduced, they were recommended not only for extreme hardness, but for the high prices at which the fruit would sell. It is found now that there is little market for them, and they will not sell for nearly the price paid for common Apples; while, the persistence with which they hang to the tree, with their small size, renders gathering slow and laborious. Dr. Reynolds, in a paper on the subject, stated that there were already more trees planted than will supply all the fruit needed, and that they could be regretted to advantage, as they make poor stocks. Mr. Smith said "Crab Apples

are not worth the picking." Mr. Wheeler thought a tree or two would be well for each fruit grower for culinary purposes. President Gilbert said there could be no reason for growing them except where the climate is such that common Apples entirely fail. A letter was read from Dr. Hoskins, of Newport, where the winters are intensely cold, and where some years ago much attention was given to raising the Crab in its many varieties, in which he says, in speaking of Crab stocks, "It has got so in Vermont that to say Crab stocks to a fruit grower would be almost at the risk of one's neck. They have had a full trial in Northern Vermont, for nearly twenty years, and the only result is utter failure. The trees begin to fail almost as soon as they come into bearing on Crab stocks." The Russian Apples, he adds, as Tetofsky and Oldenburgh, are the only sorts that endure that climate, and, although not of first quality, are profitable.—"Country Gentleman."

SCENT-YIELDING PLANTS.

By G. W. SEPTIMUS PIESSE, F.C.S.

Ilang-Ilang (*Cananga odorata*).

This plant grows abundantly in the Philippine Islands, and is especially cultivated in Manila by M. Julien, of Westembayan, to whom I am indebted for the illustrations from which the annexed woodcuts were prepared, and also for examples of the

Ilang-Ilang (*Cananga odorata*).

Champaca (*Michelia Champaca*), or false Ilang. The true Ilang-Ilang (Flower of Flowers) yields, by distillation of its blossoms, a minute quantity of an otto resembling the odour of the flower from which it is derived. The value of this otto, when pure, is from 18s. to 22s. per oz. in the European perfume market. Unfortunately, however, there grows in the same country the Champaca tree, which yields an otto, by distillation of its leaves,

somewhat resembling in fragrance that of the Ilang-Ilang, but of little more commercial value than the otto of Pimento, which realises 2s. per oz. With this the true Ilang-Ilang is frequently adulterated. The otto of Ilang-Ilang has not been introduced into Europe more than about sixteen years, but the

Flowers and Fruit of *Cananga odorata*.

price that it fetches, when pure, shows that it occupies a prominent place amongst perfumes.

Leaf Mould and Root Fungi.—In lifting a quantity of Roses lately that were in an unsatisfactory condition, I found that the lower roots were infested with fungus, evidently caused by planting in leaf mould, for all the roots that had run into the natural stiff soil were quite fresh and healthy. Leaf mould is doubtless most valuable when composed of leaves alone, but too often sticks and pieces of dead wood are largely mixed with it, and in that case it becomes a dangerous medium for fungi. As regards Roses, good farm-yard manure is generally better than leaf mould.—J. G., Linton.

Storing Ice.—If "C." (p. 227) will look at my remarks (p. 161) on ice storing again, he will find that I never recommended running up through an ice house "a chimney stuffed with straw and a central flue." I know nothing of "stacking ice in the form of a cone," I never saw one; I know, however, something of filling a vault, or well, or cellar with ice full up to the apex or top—filling up every inch with ice, but have no idea of such places being fitted with a cone. Why in a cone, which contains, geometrically, the least amount of matter for its height which any form can assume? I fully admit "C.'s" observations that ice can only melt by the action of heat on its outer surface, and certainly a cone is all outer surface; but where is the outer surface of a vault or cellar of ice wholly below the level of the ground? On the top, (certainly not the top or point of a cone), whereon the heat, the melting agent, strikes vertically, and on opening such places I have found the wasting ice with a dead flat or even concave form, containing water like a bowl; hence the advocacy of a column of straw as drainage down the centre, but not a "chimney stuffed with straw." Certainly a cone of ice needs no central chimney, seeing that a cone is little more than a chimney itself.—THOMAS WILLIAMS, Ormskirck.

PLATE CXXXII.

GLADIOLI AND THEIR CULTURE.

(WITH A COLOURED FIGURE OF MRS. BATES.)

Drawn by Mrs. DUFFIELD.

GLADIOLUS, MRS. BATES, was raised by Messrs. Kelway, of Langport, Somerset, in the year 1870, and was awarded a first-class certificate by the Plymouth Horticultural Society in 1874. It was named Mrs. Bates, in compliment to the wife of the president of that society, the senior M.P. for Plymouth. Its flower spikes, which are of the largest size, are thickly beset with blooms of the finest form, and very constant as regards colour and marking. Messrs. Kelway's name has long been associated with the Gladiolus, and few, if any, have done so much to improve it, or have been so fortunate in raising so many fine kinds, remarkable alike for their diversity in colour, and for their substance, breadth of petal, and general habit, points which Messrs. Kelway have persistently maintained were essential collectively to constitute a good Gladiolus. Their stock comprises upwards of 2,600 varieties under name, the greater part being their own seedlings. In choosing a position for Gladioli when spikes for exhibition are required, it is of the utmost importance that an open situation should be selected. There can be no doubt that a deep loamy soil, not too heavy in texture, is the most suitable for the production of spikes for exhibition, but by deep digging and liberal manuring, very satisfactory results may be obtained in soils of even an uncongenial character. Early in autumn the soil should be dressed liberally with manure from an old hotbed. After it is spread regularly over the surface, trench the soil up to a depth of 2 ft., and leave the surface as rough as possible, so as to expose a large body of it to the direct action of the frost and rains during the winter: this is of importance in the case of heavy soils, for it is very desirable that they should be thoroughly pulverised by the action of the weather. If this is done it will be in good condition for working in spring, and a pricking over with the fork will suffice to reduce it to a fine tilth, and even in wet seasons admit of the bulbs being planted without unnecessary delay. The planting of the bulbs should commence in March, and be continued at intervals of a fortnight until June. By this means a succession of bloom will be obtained from the earliest moment at which the show varieties may be had in flower until quite the end of the season. If planted in beds the rows should be 18 in. apart, and the beds must be 4 ft. in width. Beds of this size will admit of one row being planted down the centre, and a row on each side at a distance of 6 in. from the edge of the bed. As soon as the plants have made sufficient progress to require support stout stakes should be put to them. The top of the stake must not be higher than the first bloom, and the stem should have one tie only, and that a strong one of bast. After they are staked the surface of the bed should be covered to a uniform depth of 4 in. or 6 in. with partly-decayed manure. This dressing is of the greatest value, for it materially assists in keeping the soil cool and moist about the roots during hot weather. As soon as the plants show bloom liquid manure in some form is most beneficial in promoting a full development of the flowers. If for exhibition the spikes should be cut when about two-thirds of the bloom are expanded, as the lower flowers are generally of a finer quality than those towards the top.

In growing Gladioli for garden decoration it is simply necessary to select positions where they will present the most effective appearance, and there prepare the soil for them. They have a fine appearance planted in clumps between Dahlias, Hollyhocks, Phloxes, Roses, and other subjects of a somewhat similar character. They are also very effective planted in clumps alternately with Tritomads, and also associated with large masses of Cannas. They are likewise in every way suitable for intermixing with American plants, the dark foliage of which shows off the richly-coloured flowers to good advantage. The positions for them should be marked out in the course of the autumn or winter, and two or three spadefuls of manure should be dug into them. As a rule, the space for each clump of bulbs should be 18 in. in diameter, and the soil should be turned up to a depth of 18 in. or 24 in. March and April are the best

months in which to plant for garden decoration, as they are then at their best during August and the early part of September. Plant from three to six bulbs in each clump, and confine each group to a separate colour. They must be staked in much the same manner as those intended for exhibition, to prevent the wind from injuring them.

In selecting Gladioli for exhibition, Messrs. Kelway have found, after long experience, that, to insure a supply of a given number of spikes at any particular moment, a large number of sorts should be planted. That is to say, instead of planting from six to twelve bulbs of a sort, it is preferable to plant from one to three of each variety, and increase the number of sorts accordingly. For example, in purchasing a hundred bulbs, from fifty to seventy varieties should be selected. For decorative purposes it is also preferable to have a large number of sorts, because of the greater variety of colour which they afford. The improvement which has been made in this beautiful flower within the last ten years has proceeded at such a rapid rate that many of the sorts which, a few years ago, occupied a foremost position are now quite surpassed, and for exhibition purposes are comparatively worthless. We therefore select from Messrs. Kelway's collection a few of the very best kinds, remarkable alike for good form and texture, and unquestionably the best in commerce. The varieties possessing these qualities are:—

ADA, salmon-red, flaked with carmine; centre, rose, white line on each petal.

AGRIS, salmon-pink, flaked at the edges with vermillion, eye creamy-yellow; a flower of great substance.

ARIMUS, claret, flaked with purple, centre white.

BALL OF FIRE, scarlet-crimson, centre blue, maroon-spotted.

BEAUTY OF ENGLAND, white with yellow blotch, and violet stripe; a flower of great substance.

BELGICA, flesh, veined with lilac; a flower of great substance.

BRENNUS, crimson-maroon, centre white, tinged with blue, and possessing a violet stripe on the lower petals.

COLONEL PINNEY, white, slightly flaked with lilac.

DR. WOODMAN, salmon, flaked with pink and lake, and having a large blotch of carmine on the lower petal; a fine exhibition flower.

EGYPTIAN KING, maroon, with a violet stripe on the lower petal.

EUSEBIUS, scarlet, centre white.

FELIX, crimson, flaked with carmine.

LADY BRIDPORT, bluish, flaked and striped with carmine; for exhibition, one of the best in commerce.

MRS. SALWAY, crimson, spotted with white.

MR. DERRY, amaranth, flaked with purple, and lined with white; tall fine spikes.

MRS. KYMARTIN MAINWARY, dark red, flaked with maroon, spotted with white, and edged with blue on the lower petal.

OVERON, lilac, flaked with violet on lower divisions; carmine rose.

PHILIPS STUCKEY, rose with a white line, and blotched on the lower divisions.

SIR MASSEY LOPES, orange-rose, with a light centre, lower petals white, with a purple stripe; a fine flower.

VICTORY, flaked crimson, centre purple; a lovely variety.

It is necessary to observe that the bulbs should be taken up as soon as the leaves begin to turn yellow. Place them in a cool room where they can be dried gradually. When dry clean them and put them into paper bags, and store them in a dry room where they will be quite safe from frost.

Asparagus decumbens.—This plant, of which an illustration is given in THE GARDEN (p. 212), although introduced as far back as 1792, does not appear to have been cultivated in gardens until recently. It is a native of the Cape of Good Hope, and is a plant of very easy culture. In the spring—say March or April—the stems of the past year's growth die down, and if it be desirable to increase the stock, the tubers should be divided at once, taking care not to overpot them; they may then be placed in a cold frame, and will require but little attention for some time. They should be watered sparingly until the stems appear above the ground, when a more liberal supply will be necessary. Early in July they should be placed out-of-doors on a bed of coal ashes, and should remain there until the middle or end of September. By this time the stems will be from 1 ft. to 1½ ft. in length. A few plants might with advantage be placed in a temperature of from 50° to 60°, which will hasten the development of their leaves and flowers, the remainder being kept in an ordinary greenhouse temperature. The flowers, though small, are deliciously fragrant, one plant being sufficient to shed an agree-

able performe throughout a large conservatory. For dinner-table decoration it is invaluable, its pendulous, feathery spray rendering it particularly useful.—H. VERTEGANS, *Chad Valley Nurseries, Edgbaston, Birmingham.*

PREPARING PLANTS FOR TRANSPLANTING.

MUCH of the success in moving young plants propagated from seed or cuttings depends upon the way in which they have been prepared for it, especially in the case of bedding or border plants that are put out annually in order to create a display which depends upon a quick and good growth as soon afterwards as possible. The plants may be all that could be desired when transplanted, but if roots and tops are not in a condition to progress at once, weeks may be lost before they begin to grow and flower freely. It is a fact, pretty well known, that when a plant or tree is put into the ground with its roots in the form of a matted ball, it never gets proper hold of the soil, never thrives as it ought to do, and is usually short lived. The roots of such a plant never leave the surface of the ground very far, but retain the bundle form in which they were first planted, and are consequently deprived of free root action, while exposed to the vicissitudes of weather in a far greater degree than they would have been had they penetrated deeply into the ground and got a stable hold of the soil. Trees that have been planted in the condition above described, and which had made little growth, have been found at the end of ten years with their roots in almost the same warped and pot bound state that they were in when turned carelessly out of the flower pot into the ground. It is to avoid causing anything approaching this condition that the cultivator should strive in rearing plants that have to be shifted into pots or transplanted, no matter whether the plants be large or small. The exigencies of modern gardening have taught cultivators a good deal in relation to such matters, still it is only too evident, from what one sees, that we have room for improvement. One of the most notable advancements ever made was the getting quit of the "thumb pot." We have known places where bedding and other plants were raised by the hundred thousand, and yet all were shifted on from the thumb pot, entailing an enormous amount of needless work in potting, watering, moving of plants, &c., and with anything but satisfactory results as regards successful culture; nor are such practices extinct yet, though we believe there are not many who have either the time or the inclination now to shift such plants as *Lobelias*, *Verbenas*, *Calceolarias*, and such like, twice between the time of striking them as cuttings and planting them out in the beds. This brings us to the subject of

Transplanting and Boxing off Seedlings and Cuttings of such plants as herbaceous *Calceolarias*, *Cinerarias*, *Primulas*, *Cyclamens*, &c., and bedding and border plants, such as *Verbenas*, *Lobelias*, and most subjects of the tender herbaceous type in either class. The greenhouse species are sure to be healthier and freer from insect pests and disease the longer they are kept out of flower pots. From the seed or cutting pot they should be pricked out into boxes or pans; but boxes are preferable and as cheap, if not cheaper, in the end, as they are not likely to be broken. When boxes can be made for the purpose, of a handy size, 3 in. or 4 in. deep (not more), and painted, it is best, but a very serviceable article may be manufactured on wet days by a handy man from old packing cases, or from unplanned 3-in. dealers, or such other materials as may be procurable. Provision dealers have generally a good store of empty packing boxes of slim make that they are willing to dispose of, and which, when sawn up into sections about 3 in. deep and bottomed, make excellent temporary propagating boxes, that last for a couple of years or so; and such will be found useful. A few holes should be bored in the bottom of each box, or the bottom boards should be left a little open to permit drainage; but there is never much danger of the soil souring in boxes through insufficient drainage.

Pricking Out.—One of the greatest mistakes frequently made in pricking out seedlings and cuttings is the employment of a turfy or fibry compost, or the placing of such materials in the bottoms of the boxes above the drainage. Such a compost would be very suitable for a final shift, or for young plants potted off singly; but when the plants have to be shifted from the pans or boxes which they occupy with balls, such a compost renders it well nigh impossible to disentangle the roots without sacrificing the best portion of them. The roots get hold of the masses of fibre, and the plants hang together in an inextricable fashion, and can only be separated by drawing the knife through them, cutting away roots as well as soil, the result being a serious check to the plants. The compost should be well mixed and sifted through a 3-in. sieve, or even a smaller mesh for very tender-rooting subjects, and should be placed in the box without anything between it and the drainage. From such a compost it will be found that the plants will lift each with a little ball of soil attached to them, and without injury to the rootlets, unless

they have been allowed to remain too long in the box, when, of course, they will get root-bound, as in a pot, but which cannot happen if they are shifted off in a reasonable time. When young seedlings or cuttings are pricked off, they are usually entirely shaken out of the soil and dibbled into the boxes, and some prefer to make a deep, or rather perpendicular, hole, and drop the roots straight into it—a good plan in planting out permanently, but not in pricking off. A blunt dibble should be used, and a round, rather wide, and not very deep hole should be made, into which the roots should be dropped in a bunch, and the soil pressed gently over them. When the plants come to be lifted out of the box, the difference between those so treated and others which have had the points of their roots let down deeply will be apparent. The first will lift with a ball of roots clustering round the base of the plant, and ready to take possession of pot or soil, as the case may be; but the second will be found to have rambled considerably "from home" and difficult to lift with all the roots, the best of which will have spread along the bottom of the box. These remarks apply more particularly to plants that have to be afterwards transferred to pots. As to the general run of bedding plants, with the exception of *Pelargoniums*, and such subjects as are the better for a check, they should never be in a pot after they have been struck, but should be boxed off or planted out on sheltered borders, where they can be protected, or in cold frames, and from such quarters transferred to the flower beds. The idea that such subjects suffer less check by being transplanted from pots is a mistaken one. The plants may drop a little at planting if the weather be very dry and warm, but they get hold of the soil sooner, and make much greater progress than semi-started plants that have been previously coddled for six weeks or two months in small pots, and they have always the advantage of being larger and finer to begin with, for a plant in a box or bed always makes the most progress. In transplanting from the cutting or seed pot to the frame, the same rules should be observed, as regards compost and planting, as have been given above, and the plants should not be crowded; but no more room need be given them than will just allow of a moderate ball of soil being lifted with each plant. If the soil be light and finely sifted, and allowed to get slightly dry previous to transplanting, the plants will come up easily with all their roots by just grasping the plant and soil in the hand, and they should be dropped into their places in the flower bed in the same way, and with as little interference with the soil as possible. There are, however, some border plants, annuals particularly, that do not succeed with intermediate transplanting, but should be transferred from the seed bed to the border at once. *Stocks* and *Asters* are examples of this. With care they may be pricked off from the seed bed and afterwards transplanted, but the check, less or more, which they are likely to experience is sure to tell upon the quality of the flowers. The best plan with all such subjects is to sow very thinly in a fine soil laid upon a hard bottom, into which the roots cannot penetrate, and transplant from the seed bed. The seedlings will pull or lift up with the best portions of their roots intact, and, if the border has been suitably prepared for them, they may be let into the ground with a dibble or trowel, first making a deep hole, into which the tap-root should be dropped perpendicularly.

For Vegetables transplanting is often beneficial, inasmuch as it promotes early fertility in some things, such as Peas and French Beans; the latter stand the operation very well, either singly and shaken quite out of the soil, or in groups from the seed pot. Cauli-flowers are the greatest sufferers by transplanting, perhaps, of any vegetable. If pricked out in a finely divided soil, however, and lifted into good beds before they get too large, there is little danger of their "buttoning." We prefer, however, lifting the plants from the seed bed with the whole of their tap root, if possible, and planting them with a dibble, letting the roots down straight and deep into the ground. If the work be done carefully such plants always produce the finest heads. Of course, the seed should be sown thinly or the young plants should be thinned out well at an early stage. Few of the other tap-rooted vegetables, like the Carrot, Parsley, and Beet, transplant well, nor are they ever prepared for the purpose; but it is not unfrequently desirable to fill up gaps when it is too late to sow seed, and transplanting can then only be resorted to. We have transplanted all the above at times with success, when the work was carefully performed. The difficulty is not the getting the plants to grow so much as getting them to produce roots fit for use in the case of the Carrot and Beet. Everything depends on the weather at the time and getting the long tap roots up without injury and planting them safely. A good deep and straight hole should be made, the roots should be dropped into it as straight as they came up, and the soil pressed up against them, not too firmly. Watering will be necessary for a little while afterwards, especially in the case of Parsley, and if the latter can also be temporarily shaded with branches till it gets hold of the ground all the better.—"Field."

GARDENING FOR THE WEEK.

Stoves.

The sun now begins to influence the temperature of all plant structures in the middle of the day, and it often happens that during this month, more than any other in the year, the heat in the houses will rise high when the condition of the external air is such that opening the ventilators, except very slightly, would be most injurious, especially to the young, tender shoots of plants grown in stove heat; for this reason it is necessary for all who have the management of houses wherein are subjects to which continuous heat is applied to be constantly watchful of the weather at this time, particularly in the mornings, as, although it is desirable to raise the temperature without delay after it becomes light, still, if the working of the fires be not regulated by the appearance of what the weather gives promise to be during the day, the result frequently is that by ten or eleven o'clock, if it be clear and bright, the temperature of the house, from the combined effects of the sun and unchecked fires, is so high as to necessitate the admission of more air than should be given, which in addition to its chilling influence, dries up the atmosphere of the house in a way that causes the tender foliage to flag severely, and I have noticed with stout-leaved subjects like *Ixoras*, *Gardenias*, and *Medinillas*, that the young leaves which thus droop much are often permanently disfigured, and though the after progress made by plants so affected may be such as to lead to the supposition that little harm has been done, still there is no doubt from the sympathy which exists between the leaves and roots, that the latter suffer through any injury to the former, and the whole plant must be proportionately affected thereby. Thus the necessity there is for daily keeping a look-out as to the weather, and stopping the fires sufficiently with a view to avoid the temperature rising too high becomes obvious; but, should this occur, less mischief will result by letting the thermometer run up to 90° or 95°, with a little air on, than by reducing the temperature about 10° through the admission of too much air. Plenty of water thrown about on all evaporating surfaces helps to counteract the effects of heat rising higher than desirable. It is almost needless to say that sun heat is very much preferable to that derived from fire, and with this view continual watchfulness is requisite to utilise the sun heat, as far as possible, by not allowing the afternoon to get too far advanced, so that the sun has got off, or almost off the glass, before taking off what little air may have been given. In fact, with a good light stove, the plants well up to the glass, and a constant look-out for the weather, I have frequently been able to get through this month with the admission of very little external air, to the evident benefit of the plants.

Shading.—The shading of stoves, like that of all other structures, can only be looked upon as a necessary evil, never to be employed except when and where unavoidable. In the stove the more or less necessity of shading will be determinable by the description of the subjects grown and the position of the house. A house of any form facing the south, where the sun in the middle of the day comes directly upon the occupants needs shading for a time on the sun-exposed side for almost any kind of plants, whereas, in the case of structures placed in the opposite direction, the bars and rafters break the force of the sunshine, and this, coupled with its striking them obliquely, much reduces the necessity for shading, and, with houses so situated, I for some years ceased altogether to shade such plants as *Ixoras*, *Dipladenias*, *Gardenias*, *Rondeletias*, *Allamandas*, *Bougainvilleas*, *Gloxinias*, *Achimenes*, *Euphorbias*, or anything with stout foliage, excepting that when some of these were in bloom they were very thinly shaded, with a view to shield the flowers. The increased quantity of bloom produced and the general appearance of the plants proved non-shading to be an advantage. The large numbers of tender-leaved, fine-foliage subjects, such as *Cyanophyllums*, *Sphærogytnes*, *Caladiums*, *Alocasias*, and some *Palms* absolutely require shade when the sun is powerful, as otherwise, if the foliage be not positively burnt, it gets so brown as to make it unsightly. It is much the best plan to put those plants, both flowering and fine-leaved, that want shade, at one end of the house, using shade there only. It cannot be too often impressed upon beginners in the cultivation of stove subjects that the blinds in all cases should be movable, and that they should never be down before there is absolute necessity for it, nor to fail in rolling them up as soon in the afternoons as they can be dispensed with. The material used should also not be thicker than just to break the force of the sun's rays.

Achimenes and Caladiums.—*Achimenes* for late blooming that have not been started, should at once be put into heat. Those first started in pans will shortly be ready for placing in the pots or hanging baskets in which they are to be grown. For large houses

there is nothing more effective than these plants in good-sized wire baskets suspended from the roof. For general purposes pots of small or medium size will be found the most useful. Their rapid growth necessitates a liberal supply of water through the growing season, for which reason see that the drainage is efficient. Any *Caladiums* not yet started should immediately be shaken out and repotted. These will be serviceable, retaining as they do their leaves fresh and in good condition through the autumn. If there be a deficiency of any kind when the young crowns have got 6 in. or 8 in. in length, they may be cut out from the tubers, placed singly in small pots, and treated as is usual in the case of cuttings, in which way they will shortly get established.

General Propagation.—Cuttings of most stove plants root freely in a much shorter time than those of the generality of greenhouse subjects. Many of the hardwooded plants that were recommended to be headed down some time back, will soon have made shoots that will furnish the best kind of cuttings, as, when they get a few inches long, if severed at the junction with the old stem, they are in the best possible condition for making good plants in a short time, as these shoots have always a less disposition to flag when not so closely confined under bell-glasses or in a propagating frame, and are comparatively less liable to damp off than cuttings made from growth further developed. For general decoration, small and moderate-sized examples are of more use than large specimens, and, in the case of quick-growing plants, it is well to err on the right side by having enough of *Gardenias*, *Clorodendrons*—both shrubby and climbing—*Allamandas*, *Dipladenias*, *Rondeletias*, *Vincas*, *Tavernerianthus*, *Stephanotis*, *Rogieras*, *Medinillas*, *Lononias*, *Lasiandras*, *Hibiscus*, *Hoyas*, *Aristolochias*, *Bougainvilleas*, *Apelalandras*, *Æschynanthus*, and *Abutilons*; of these sufficient cuttings for whatever may be required should at once be put in. Young plants of the majority of soft-wooded stove subjects, being of quick growth, are better than old ones. Cuttings of *Impatiens*, *Meyenias*, *Pentas* [earnea], *Torenia*, and *Eranthemums*, should likewise be put in in all cases, seeing that they are clear of insects.

Propagation of Fine-leaved Subjects.—Cuttings of *Cyanophyllums*, *Aralias*, *Crotons*, *Dracenas*, *Ficuses*, *Hippomane spinosa*, *Rhopalas*, and *Sphærogytnes*, should be taken off as soon as they are large enough for the purpose. In the case of most of them the young shoots that are formed after heading back root much more readily than the points of the strong branches, especially when obtained with a heel, as they can be got at this stage of their growth. All the larger-leaved species of this description require sufficient room in the cutting pots, or they are liable to damp off, and every effort should be made to retain in perfect condition the whole of the leaves which they possess, as upon being clothed with perfect foliage down to the base depends their appearance afterwards. Plants that require to be increased by division of the crowns are easiest managed about the time when they commence growth. Some of the species of *Pandanus*, *Musas*, *Hedychiums*, *Cyperus*, *Anthurium*, &c., may therefore now be divided as wanted, potting the pieces separated singly and keeping them close until they have become established.

Ardisia crenulata.—Both the red and white fruited varieties of this plant, when well managed, are amongst the most useful berry-bearing subjects which we have. Where young shoots are obtainable they should now be propagated, putting them separately in small pots, or, if in larger numbers together, taking care that they are so treated that whatever leaves they possess may sustain no injury. For table or room decoration they are deservedly great favourites, lasting as they do with care in good condition for months. They are equally suitable for standing about on the side stages of stoves, intermediate houses, and warm conservatories, where, if slightly elevated above their associates, they are very effective; but if considerable numbers are wanted, it takes some time to get up a stock from cuttings, and beautiful plants may be raised from seed, which if sown now in pots or pans, drained and filled with open sandy soil tolerably compressed, the seeds slightly covered and placed in a brisk growing temperature, after some time the seedlings will make their appearance, but they are slower in all stages than many other plants.

Bouvardias.—A sufficiency of outtings should at once be got in; they will succeed either made from the roots or shoots; where enough of the latter are not at hand, a good-sized plant or two will provide a number of the former, using the stronger pieces in bits from $\frac{1}{2}$ in. to 1 in. long, putting them in pots or pans partially filled with sandy soil, the upper portion being set alone, and inserting them about level with the surface of the material. If kept moist and warm, they will soon commence to grow, and they should be placed singly in small pots as soon as large enough to handle.

Greenhouse.

Azaleas.—Those that were forced early, and their flowering now over, should at once be placed in heat to encourage a continuance of the growth, which would be more or less excited by the warmth to which they were subjected, in order to bring them into bloom. Sometimes these early forced plants, after flowering, are for a time submitted to cool treatment, with a view to their being placed in a growing temperature along with those that bloom later. There are two reasons that point to this treatment being wrong; first, it necessarily has a stunting influence upon the shoot growth; secondly, the opportunity is lost of getting their growth made early and the bloom buds formed, by which means there will be little difficulty in getting them into flower at a correspondingly early period next winter with comparatively less heat, a matter of considerable importance, whether the plants are required for ordinary decoration or the flowers for cutting. Previous to putting them into warmth they should be closely looked over to see that they are free from thrips; should any trace of these be found the plants ought to be either fumigated, dipped in Tobacco water, or syringed with that liquid. Any that require larger pots it will be better to defer moving till some further progress is made in the growth of the young shoots as, until this takes place, the roots of Azaleas do not begin to move.

Heaths.—Directions were recently given as to the potting of hard-wooded plants generally, but Heaths need to be treated exceptionally in this matter. Although the roots of most of the species and varieties are extremely fine and impatient of excesses of any kind, still the majority of the garden hybrids naturally form such quantities of fibres, that to keep the plants in the vigorous condition necessary to their being clothed with healthy foliage and abundance of bloom, they require larger pots than any other plants of such comparatively slow shoot growth, and wherever they are allowed to remain with their roots too much confined, they invariably get into a stunted state, from which they rarely if ever recover. This does not apply alone to the harder-wooded section, but also to the softer, winter-blooming kinds, which, to keep them in a healthy condition beyond the size of the ordinary trade-flowering plants, must have a sufficient amount of pot room. I have seen the winter-blooming *Erica hyemalis* when planted out in a prepared bed on the floor of a light greenhouse, attain a height of 5 ft. and as much through, flowering so profusely every season as to permit of the branches when in bloom being cut in pieces 1 ft. or 15 in. in length. I mention this to give some idea of the vigour that plenty of root room gives to plants for which it is often supposed very limited root space is sufficient. The majority of Heaths like peat of a closer and heavier character than most other hard-wooded stock. Early autumn for the potting, especially of large Heaths, is preferable to spring, but where the stock, large or small, is likely to suffer from want of additional root room before the summer's growth is completed, it is much better to pot now, in all cases paying particular attention to the efficiency of the drainage, and see that the soil contains sufficient sand to keep it sweet and permit the water to pass through it when rammed tightly into the pots in the way necessary in potting Heaths so as to grow them well. To still further insure porosity, a moderate sprinkling of clean pot-shreds, broken about the size of horse Beans, incorporated with the soil, will be an advantage. After potting restrict admission of air and prevent the atmosphere of the house in which they are placed getting too dry.—T. BAINES.

Flower Garden.

Auriculas.—These, when in flower, suffer more readily from the effects of sunshine than almost any other flower; it is, therefore, necessary to remove those that have any pips open to a place by themselves, to avoid shading plants that are in flower. Old-fashioned growers objected to placing sticks in the trusses; they were anxious to show that the flower stalks were so stout and elastic as not to require any such extraneous aid. Some kinds, however, require a little support, and I do not scruple to give it. I use for the purpose small Willow twigs cut into suitable lengths. If the work be properly done the sticks will scarcely be visible. When the plants are being moved, or subjected to any kind of manipulation, one must be careful not to rub any of the white powder or farina from the leaves or flower stalks.

Carnations and Picotees.—The Tree or perpetual flowering varieties of Carnation require attention at this time; they produce plenty of blooms when raised by a warm greenhouse temperature; the stems should be tied to sticks, else the weight of the flowers bends them down, and they snap at the joints. Some of the large, full flowers are very beautiful, but nearly all of them burst the calyx, unless it be tied round before the flowers open with a strip of matting. See that a goodly number of cuttings of all the varieties are put in for flowering from January to June next year. The very smallest offsets, if inserted in sandy soil, will soon form roots on a gentle hotbed.

Hollyhocks.—Instructions as to planting out choice-named varieties have already been given in THE GARDEN (p. 208); see, therefore, that this operation is carried out as soon as the plants have been inured to the open air. Later-propagated plants should be placed in cold frames when they have become well established, and they must also be speedily hardened off. For ordinary decorative purposes seedlings make the best display, and if the seeds be saved from the finest double flowers there will be comparatively few inferior varieties amongst them. If the seeds be saved from varieties of decided colours, without crossing, the seedlings will vary but little from their parents, and half of them will be as good.

Pansies.—A few pots may be removed from frames to the greenhouse, where their agreeable perfume and rich colours will be appreciated. They ought not to be placed there until they are in flower, as, if at a distance from the glass, the growths soon become drawn up weakly. Cuttings may now be put in to produce late flowers of a better quality than can be obtained from old plants. The flowers of show Pansies very speedily deteriorate in quality unless all of them are picked off at frequent intervals in order to allow the plants to have a short rest. The growths ought to be thinned out, and the surface of the soil dressed with rich compost, when the young shoots may be pegged down over it.

Primula cortusoides, and also all hardy Primroses, give the greatest satisfaction when grown under glass; they can be attended to at the same time as Auriculas, and much in the same way. The great advantage of growing such plants in pots under glass is, that the flowers can be inspected in all sorts of weather, and they occupy such a very small space, that they may find a place in the smallest gardens. We had a small bed of *Primula cortusoides*, which stood out without any attention for several winters, but the plants were ultimately lost. We are now planting out a bed of the white, lilac, and red forms of *P. aemona*; planted at this time, they will flower as strongly as the plants in pots.

Delphiniums, Phloxes, and Pyrethrums in beds, if they have not been replanted, should now be attended to without delay, as some of them have made considerable growth. Delphinium seeds, if sown now in heat and well attended to, will produce flowers in succession to the old established plants. *D. formosum* and *D. Madame Henri Jacotot* are two of the very best; these seeds should be sown in spring. The one has bluish purple flowers, the other blossoms of a beautiful clear light blue.

Tulips.—With us the florist section of Tulips in beds are making exceedingly strong growth, although late in comparison with that of the last few years. On the first favourable opportunity we will surface dress the beds with rotten manure; this acts in two ways—it prevents evaporation, and keeps an equable temperature round the roots.—J. DOUGLAS.

Hardy Fruit.

If pruning of all kinds, staking, tying, and nailing be finished, as by this time they should be, attention must now be directed towards devising ways and means for protecting the trees when in blossom. Here the first Apricot flower opened on the 10th; it was full and as well developed as if we had had no hard and protracted winter, a fact worth recording, as previously we had certain misgivings in the matter, having found a few Pear and Cherry buds blackened right through. A recurrence to sunless days, and bleak "north-easters" has, however, had the effect of retarding any further expansion of fruit buds, and though it will now be late ere Peas, Peaches, Cherries, &c., open, still the necessary protection should be ready if required. Though the trees are backward, any grafting that has to be done had better receive attention at once, for the double reason that there is now more leisure for doing it, and that it is very probable that when a change does take place growth will be very rapid, and, consequently, a good grafting time be very limited. Any trees that are languishing through poverty of soil, or over-fruiffulness, may be rendered vigorous by now removing the surface soil right down to the roots and replacing the same with good maiden loam, and a liberal admixture of well-decayed manure. Well press the soil about the roots and finish off by a thick coating of manure on the surface as far as the roots of the tree extend. The surface-dressing and manuring of Raspberries should no longer be delayed. No hardy fruit crop so soon shows the good results of manurial dressings, or gives better returns than these, and this fact should be an incentive to the accomplishment of the operation. Thin out straggling branches or boughs, and eradicate the suckers from round about the stems of Nuts. The value of the suckers thus removed for various purposes will pay for the labour, not to mention the benefit accruing to the trees, as root suckers are little better than parasites, for they live on the vitality which would otherwise aid in the production of more or better fruit.—W. W.

Kitchen Garden.

Here, in the south-west of England, the past fortnight has been a glorious seed time, and all our kitchen garden crops which require to be got in early have been sown. Onions, Parsnips, Early Horn Carrots, Peas, Broad Beans, Radishes, and Lettuces, have all received attention in that way; Shallots, Garlic, and a good batch of early Potatoes have been planted. All of these, where not yet sown or planted, should have immediate attention, and every endeavour should be made to bring up arrears of work, the result of the long winter, from which we have hardly yet escaped. Preparation should be made for planting the principal plot of Potatoes, deep tith, moderately enriched soil, thorough drainage, head-room for the haulm by planting the tubers a good distance apart, and medium-sized seed tubers with but two sprouts, constitute all that is required in order to ensure success. Peas and Broad Beans should be sown successively, according to the demand. As a rule, as soon as one lot emerges above the soil, another should be sown. Earth up and stake Peas, and on the cold or windward side screen them with Laurel or other evergreen boughs. Sparrows and chaffinches at this early season have an insatiable taste for the tender tops, and when once they commence their attack, nothing short of annihilation will deter them. Radish, Turnip, Broccoli, and Cabbage seeds are equally dainty morsels to these pests, and, unless netted over as soon as sown, woe betide them as soon as the first chaffinch finds them out. Cauliflower plants wintered in hand-lights should now be finally thinned out, about three of the best being left to mature on the ground; the remainder should be carefully removed with balls of earth, and planted in the warmest available position. A deep drill helps to ward off cutting winds, and as soon as the plants get sturdy it can be filled in level, and no other earthing up is required. Prick out Cauliflowers sown in heat a few weeks ago; a south border and a little evergreen branch protection are all that is required. Such plants will make a good succession to those now being planted. Brussels Sprouts and early Cabbages should be treated in a similar manner. As to other seeds to be sown, planting to be done, and other routine work, consult *THE GARDEN* (p. 167 and 208). The heavy work now requiring attention will be the digging out of Celery trenches, clearing off stems of Broccoli, Brussels Sprouts, and other winter greens, and preparing the ground for Potatoes, Spinach, Peas, Runner Beans, and the like. Let all the walks and edgings be put in good order, and maintain neatness at all times by arranging that wheeling over the walks or all other heavy traffic be done, either on frosty mornings or during the prevalence of drying winds.—W. W.

Extracts from my Diary, March 24 to 29.

FRUIT.—Top-dressing pot Vines. Tying and stopping Muscats first time. Shifting Strawberries. Grafting Gros Colman Grape on Pearson's Golden Queen, and Harewood Muscat on the Trebbiano. Looking over Apples in fruit room. Disbudding Peaches in second house. Sowing batch of Melons. Planting Pines in frame. Disbudding Nectarine at end of late Vinery. Shifting ripe Strawberries into cold house. Thinning Grapes in pot Vinery. Emptying Pine pit and mixing manure and leaves for hotbed. Potting Vicomtesse Héricart de Thury Strawberries for fruiting at Christmas. Watering cold Peach houses. Tying Muscat Vines. Getting in fresh batch of Strawberries into Vinery. Hybridising Cherries in cold houses. First Hamburgh Vines in flower. Peaches in cold house set; also Early Amber Cherries. **FLOWERS.**—Propagating Lobelias, Petunias, and Ageratum. Sowing Phlox seed. Putting in cuttings of Euphorbia jacinthiflora, and sowing seeds of Poinsettias. Shifting Alternantheras, Mesembryanthemum, and Petunias out of cutting pots into 3-in. ones. Sowing Primulas and Cinerarias. Nailing Camellias on Peach house walls. Putting Primulas into cold frame. Pricking out Pyrethrums into boxes. Boxing Iresines and Lobelias. Breaking up old stools of Begonia Weltoniensis, and potting them; also potting Caladiums and fancy Pelargoniums. Tying Roses and freeing them from snokers. Potting Miles' hybrid Mignonette. **VEGETABLES.**—Sowing Sweet Basil and French Beans; also main crop of Onions and a little Lettuce. Planting Potatoes for exhibition; also batch of French Beans. Sowing Leeks. Preparing ground for planting show Potatoes by giving it a dressing of ashes and sawdust. Planting McKinlay's Pride Potatoes.

Potatoes and Frost.—"A. D." (p. 206) is right so far as the frost question goes. But I cannot admit that Myatt's Kidney and Gloucestershire Kidney are identical with the old Ashtop. I have every respect for dear old Chiawick, and also for the authority of the fruit and vegetable committee—still, I only take their opinions for what they are worth.—R. GILBERT, *Burghley*.

THE LIBRARY.

POTATOES—HOW TO GROW AND SHOW THEM*.

As a skilful cultivator and a most successful exhibitor of Potatoes, Mr. Pink is entitled to give full and free expression to his views concerning them, and out of his experience, aided by helps from other sources, he has produced a book that promises to be most useful. It is, perhaps, unfortunate that the title should so imperfectly foreshadow its contents, for, besides directions for growing and showing the Potato, there are chapters upon the history of its introduction to this country, its botanical character, the cause of the disease, suggested remedies, the Potato as an article of food, and other matters of much interest. Thus the book is more comprehensive than its title indicates, whilst on the other hand, it falls somewhat short of what a book upon the Potato should be. This, however, is a defect that time may remedy, as it is a singular fact in relation to this valuable esculent, that information respecting it is certainly on the increase, and with new sorts and fresh experience, the phases of its culture are continually changing. On the special topics of the book—growing and showing—Mr. Pink treats fully, devoting chapters specially to the preparation of the soil and to manures and manuring. As regards manures, he enters into some elaborate chemical details, and appears to favour the application of special manures rather than our farmyard composts. In one respect there is a seeming inconsistency in his statements, as in one place he says, "Poor soils never produce good crops, nor are the Potatoes from them of first-class quality;" and later on we have, "The quality of the tuber is never so good when stimulating manures have been applied to the growing plant." If Potatoes grown on poor soils are devoid of quality, in an inverse ratio those grown on rich land ought to be specially good; but such is not the case, and the wisest grower is he who avoids all rich manures, and yet has his land in fairly good condition, fertile in phosphates and other Potato constituents. The chapter devoted to planting and after cultivation, is the most exhaustive and practical in the book, because it consists largely of the author's own experience, and details the various methods of planting, as applicable to different soils and positions. The ridge system of planting is recommended for stiff, heavy lands, and the flat system for ordinary soils. It may not, however, be understood, that when strong growing kinds are planted on the flat system the same distance apart as when planted on the ridge, the result is about the same, as each plant develops into a ridge in the end, if the rows be properly earthed.

Growers for show are often greatly troubled with the wireworm, which will pierce the tubers and greatly injure them. Mr. Pink recommends the placing of pieces of rape cake in the rows at intervals, as the worms will attach themselves to these baits, and may be removed in considerable numbers with the pieces of cake about the time when the plants are through the soil. This is no doubt a much more practical plan than merely rolling the soil, as no amount of pressure thus applied, short of absolute crushing, would destroy this troublesome pest.

Earthing-up is recommended to be done gradually, and not all at once, as the gradual gathering of soil about the roots tends to the formation of tubers from the stems. Of course it is evident that if Potatoes are being grown for exhibition much more care and attention must be given to the plants than would be necessary under ordinary culture.

The concluding chapter is entirely devoted to exhibiting, selecting tubers for that purpose, packing, and staging them, subjects also treated of in a small pamphlet just issued by another famous exhibitor, Mr. Porter, of Old Meldrum. Mr. Porter's exhibits have always been remarkable for natural polish, and this he chiefly attributes to the presence of a good dressing of pounded charcoal sown with the seed tubers. Mr. Pink's book is illustrated with engravings of some well-known Potatoes; it is neatly got up, and contains a large amount of useful information concerning the subjects on which it treats. A. D.

* "Potatoes—How to Grow and Show them." By James Pink. London Crosby Lockwood & Co.

GARDEN DESTROYERS.

THE BROWN-TAILED MOTH.

(PORTHESIA AURIFLUA.)

THE caterpillars of this moth are very similar in their habits to those of two species which we have already described, viz., the small ermine moth and the lackey moth, though it does not belong to the same family as either, but to the family Arctiidae. Fortunately, this insect is seldom so commonly found as the other species, but occasionally they appear in great numbers, when the mischief they commit is proportionately great. They feed on a great number of different trees; their favourite food appears to be the leaves of the Oak, Elm, White Thorn, Black Thorn, and most fruit trees. Like many insects, in some years they are much more abundant than in others, and having been particularly abundant one year, are perhaps hardly to be seen for several years afterwards. This species was so abundant particularly near London in 1872, that, according to Mr. W. Curtis, the greatest alarm was occasioned, not only for the trees and hedges, but also for the corn and Grass crops; one shilling per bushel was paid for the webs of these caterpillars, which were burned in the presence of the churchwardens or other parochial authorities. Prayers were offered up in some churches that the country might be delivered from

Caterpillar of *Porthesia auriflua*.

this plague. In such numbers were these pests, that eighty-one bushels were collected in one day in the neighbourhood of Clapham. Though of late years nothing of this kind has been experienced, still great injury has been done, particularly to fruit trees, at various times by this insect. Unfortunately, there is not much that can be done to lessen its numbers, except by waging war against it on all possible occasions. The moths, on account of their size and colour (pure white) are easily seen, and as they are very sluggish during the day, may easily be shaken from the trees and destroyed; wet and cold weather kills great numbers of them. Many of the eggs are destroyed by a minute, four-winged fly, hardly visible to the naked eye, which lays an egg in each of those of the brown-tailed moth, which are soon destroyed when the little grubs are hatched. As the eggs are laid in clusters on the under side of the leaves, they can easily be detected, if carefully looked for. The caterpillars may be found at the points of the branches sheltered in their webs formed among a few leaves. During the winter these bundles of leaves should always be cut off and destroyed. In the spring the trees should be well looked over, so that any injuries which are being committed may be detected, and at once checked. The caterpillars are, unfortunately, so hairy that birds seldom touch them; they should always be carefully handled, as their hairs come off very easily and stick into the skin, causing a considerable amount of irri-

tation. They suffer much, however, from the attacks of several species of Ichneumons, which assist very much in keeping down the numbers of this insect. The balls of leaves containing the chrysalides should be carefully destroyed. The moths are first seen towards the end of June, the females soon afterwards begin to lay their eggs. The care they take in this proceeding is very remarkable and interesting. Having selected a suitable position, generally on the underside of some leaf, she deposits her eggs, about 200 or 300 in number, and yellowish in colour in a heap, which she carefully covers with the tawny-coloured hairs with which the end of her body is provided. These hairs she is said to pull from herself by means of a small pincer-like organ which the extremity of her body is provided with. The caterpillars are generally hatched in August, and, at first, only feed on the softer parts of the

Moth of *Porthesia auriflua*.

leaves, which they somewhat curl up by spinning threads from one side to the other, under the shelter of which they live secure from the attacks of foes, and protected from the weather. When this leaf is reduced to a skeleton, the caterpillars remove to another, and as they increase in size, they begin to form a regular nest by fastening several leaves together, and covering them with a thick web; they attach the nest very securely to the branch, so that when the leaves die over which it is made, they cannot fall and carry it with them. The caterpillars now seek their food from the nearest leaves on the branch, and only return to the nest for shelter; they change their skins for the first time in August, and leave off feeding in September or October, and soon become torpid, in which condition they pass the winter within their nests. From experiments which have been made on them, they seem to be able to withstand almost any amount of frost without injury. The same influences which cause the buds to open in the spring seem to reanimate the caterpillars, and they at once begin feeding on the opening buds. It is at this season that they do the most injury to the fruit trees. At the end of May they change their skins for the third time, and then spread themselves over the trees, no longer keeping together in any way or returning to the nest. In June they roll up several leaves with a brownish web, within which they undergo their change to the chrysalis state; sometimes several chrysalides may be found within one web. The moths measure about $1\frac{1}{2}$ in. across the wings, and are pure white in colour, with the exception of the last three or four joints of the body, which are brownish. The antennae are very deeply toothed in the males; the thorax and body are densely covered with long hairs, which, at the extreme end of the latter, form a kind of tuft. The caterpillars, when fully grown, are about $1\frac{1}{2}$ in. in length and of a brownish-black colour, with tufts of dark grey hairs; on the back of each joint, with the exception of the first, are two pure white spots, forming two longitudinal rows down the back of the caterpillar; between these rows is a double bright red line, and on each side of every joint is a reddish-brown tubercle, those on the same side being connected together by a red line. On the back of the fourth and fifth joints there is a fleshy hump; on these, and on the middle of the back of the other joints, as well as on the side tubercles, there are tufts of long grey hairs. The first three joints, the sixth, seventh, eighth, ninth, and last joints bear legs. The chrysalides are dark brown surrounded by a coarse brownish web. S. G. S.

Myosotis dissitiflora Injured by the Weather.—If "A. D." (p. 202) will winter this Forget-me-not under a north wall, he will find it much less liable to be injured by frost. I have a quantity of the true variety, all struck from cuttings put in last June, looking fresh and quite green, but not yet in flower.—R. GILBERT, *Burghley*.

Glass Labels.—Owing to upright wooden labels looking so very ugly in an Alpine garden, I procured from a glass manufactory the refuse of green bottle glass in large lumps. These were beaten to pieces about 1 in. square of irregular form, and the names of the plants were written on the flat side with a diamond. These labels are of course very durable, look well, and are not disagreeably conspicuous.—O. F. AUGSBURY, *Bavaria*.

NOTES FROM KEW.

Hardy Plants.—A charming companion to the many coloured forms of the ordinary Hepatica is the large Hepatica (*Hepatica angulosa*). It is of tufted habit, growing nearly a foot high and as much through. It has coarsely-toothed, heart-shaped leaves, and produces an abundance of blossoms over 1 in. across, and of a beautiful sky-blue colour. It is admirably adapted for partially shaded borders or even fully exposed if it be planted in stiff soil. It is a native of Transylvania, and, though an old introduction, is still far from being common. Another beautiful Windflower is *Anemone Paleatilla*, commonly called the Pasque Flower. It is one of our most ornamental indigenous plants, though now somewhat rare. The whole plant is covered with soft, silky hairs; the leaves are deeply cut into numerous narrow divisions, and the blossoms, which are 3 in. across, are of a pale purple, with a bright yellow centre. It inhabits dry chalky hills and similar exposed places throughout Europe and Siberia. Among the Hellebores are some really desirable kinds, such as the Hungarian *H. atrorubens*, which grows about 1 ft. high, and bears fine dark purple flowers. Much resembling it is the Abchasian Hellebore, which apparently differs in being taller, the flowers smaller and more cup-shaped, and the flower stalks being more leafy. The Olympian Hellebore (*H. olympicus*) sometimes called Kamtschatkensis, is a handsome kind with blossoms almost white. There are also some labelled Berlin seedlings, one of which is especially noteworthy; its flowers are purple and very copiously spotted with dark red; the sepals moreover differ from those of the others, inasmuch as they are decidedly pointed. Most probably this variety is the result of a cross between *H. abchasicus* and the Spotted Hellebore (*H. guttatus*). The many forms of the Green Hellebore (*H. viridis*) are also well represented, but as they are not interesting generally, further comment in reference to them is unnecessary. Turning to the Crocus beds we have, in addition to those enumerated last week, several other little gems, comprising *C. veluchensis*, or as it is called in some collections, the White-beaked Spring Crocus (*C. vernus leucostylus*), a name very aptly applied, as the tips of the petals are of the purest white, appearing more conspicuous on account of the deep, purple, Y-shaped mark immediately below it similar to that in *C. bantianus*; the lower part of the flower is of a lighter hue. As yet it is very rare in cultivation. It is a native of Greece and Transylvania. It may not be out of place to add that the figure bearing this name in the "Botanical Magazine" (tab. 6197) does not represent the plant in question, but the plate by Dean Herbert in the "Botanical Register," 1817 (tab. 4) is an excellent portrait of it. *C. Olivieri* (syn. *C. Aucheri*) a pretty yellow-flowered kind is distinct on account of its globose flowers and broad foliage. Some complain of its being a shy bloomer, but in a stiff loam and fully exposed it is remarkably the reverse. It is found in Greece and Asia Minor. The elegant little *C. stellaris* is supposed to be a hybrid between *C. latens* and *C. susianus*, and, judging from the colour, this origin is very apparent, as it has the dark marking of the latter disposed in fine lines on the outside. *C. Siebe* and *C. reticulatus*, from its curiously-netted bulb coats, are old but very desirable kinds; the former particularly so, as it comes in so early and keeps up a continuous show. The Juniper-leaved Saxifrage (*S. juniperifolia*) is an exquisite Alpine Gem, forming dense, cushion-like tufts of sharp-pointed Juniper-like leaves, and throwing up about 2 in. high, little tassell-like heads of golden-yellow flowers. Such a distinct kind needs no pen to recommend it. The typical form of the netted Iris (*Xiphion reticulatum*) has now expanded its first flowers, and, as remarked last week, is much superior to the variety Krelagei, though later. This remarkably handsome bulbous plants should be accommodated in every garden, be it large or small. A sunny border, consisting of a good sandy loam evidently suits its requirements capitally. Those who possess it should keep a good look out for the ripe seed pods a few months hence, as the seed readily germinates if sown as soon as it is ripe. *Trillium nivale* is a rare little Alpine species, remarkably distinct from the other cultivated kinds on account of its small size, and also its flowers being borne quite erect. It is not more than 2 in. in height, and has a whorl of three small pale green leaves. The blossoms are large for the size of the plant, being 1 in. across, of a triangular outline, and of a pure white colour. It inhabits shady Pine woods in the Eastern States of North America.

Orchids.—One of the most singular as well as rare of the numerous family of Dendrobiums is the tongue-leaved kind (*D. linguaeforme*) found in the vicinity of Moreton Bay. It has oval, tongue-like leaves, 1 in. long, and thick in proportion, and produces erect racemes of pure white blossoms with attenuated petals, so characteristic of the majority of the North Australian Dendrobies. It apparently succeeds well when merely fastened to a block of cork or wood. *D. primum* is a very showy kind, having a pendulous habit and flowers over 1 in. across with a rounded, crisped lip, and uniformly of a deep rose colour; the form giganteum is desirable on account of its

superior sized blossoms; both are natives of the East Indies. *Odontoglossum triumphans* is one of the finest of its section. It has flowers quite as large as those of *O. luteo-purpureum*, but the markings are far brighter. It was discovered about a dozen years ago by M. Linden at high elevations in New Granada. The rather shy-flowering Alos-leaved *Cymbidium* (*C. aloifolium*) is very conspicuous with its drooping spikes of dark chocolate and white blossoms developed from the base of the narrow, leathery leaves. It is a native of the East Indies and is also known as *Acerdis* Borassi. A sweet-scented *Odontoglossum* (*O. odoratum*) at once reminds one of *O. gloriosum*, but its smaller and sweetly-scented blossoms render it very distinct. It is found at lofty elevations in Merida, and, as yet, appears to be somewhat rare in collections.

Stove Plants.—*Dalechampia Roeziana* is a very ornamental stove plant belonging to the Spurgewort family. It has a dwarf, shrubby habit with leaves of the size and form of the leaflets of the common Horse Chestnut. The point of beauty consists in the two heart-shaped floral leaves, as in the Bougainvillea, which are, in the type, of a pale pink colour enclosing a tuft of bright yellow flowers. These have the consistence and veining of true leaves, therefore last a very considerable time in beauty. The variety rosea is a decided improvement, as the bracts are larger and of a deeper shade; the white form, too, is desirable for the sake of variety. The showy *Pancratium* (*P. speciosum*) a native of the West Indies, is one of the finest of the genus, being of bold habit with spreading, ample foliage, and producing several stout flower stems terminated by an umbel-like cluster of about a dozen blossoms having narrow segments 6 in. across and a funnel-shaped corona, the whole of snowy whiteness save the golden-tipped stamens; it moreover emits a delicious perfume. In the Cactus house the very handsome *Cereus Mallisonii* is flowering profusely. It is apparently of pendulous habit, and is grafted on the magnificent night-flowering *Cereus* (*C. MacDonaldii*). The flowers are large, of a deep scarlet colour, and though they are rather fugitive they are borne in continuous succession.—W.

NOTES OF THE WEEK.

New Himalayan Primrose.—There is in Mr. Ware's nursery, just coming into flower, a charming new Primrose, a Himalayan species under the name of *Primula rosea*. It is quite new to cultivation, but known long ago, as it is figured in "Royle's Illustrations of Himalayan Botany." It originated from seeds distributed from Kew in 1877. The colour is a pleasing shade of rose without the suffusion of a purplish tinge so often seen, and the pipes are each the size of a sixpence. The foliage is of a bright emerald green and appears along with the flowers. It is, we consider, one of the most charming additions to hardy plants that we have had for some years, and, being of a tolerably robust constitution, it will soon become common.—W.

Daphne Mezereum.—Bushes of this now form very pretty objects on the Grass or in shrubby borders, being, as usual, loaded with purple flowers that are delightfully fragrant. The evergreen Spurge Laurels are, I find, most useful for furnishing beds under trees, as they flourish in positions where little else will grow, and although not conspicuous as flowering shrubs, their fragrance, especially in the evening, is very agreeable. One need not see them to be made aware of their presence.—J. G. Linton.

Platycerium grande.—There are some plants which, although by no means difficult to grow when fairly well treated, yet nevertheless never become very plentiful; to that class belongs this Stag's Horn Fern. We recently saw several fine examples of it in Messrs. Jackson's nursery at Kingston, where, growing on pieces of wood to which there was a sufficient quantity of material for the roots to extend in, and be kept moist, plants of it thrive well, and measure from 3½ ft. to 4 ft. across. They are in an Orchid house, kept moderately warm.—F. G.

Rhododendrons and Camellias at Glasnevin.—The Rhododendron and Camellia house at Glasnevin is just now unusually gay and interesting, while most plants out of doors still have a wintry look. On R. arboreum and its varieties there are hundreds of flower heads, and standing very conspicuously amongst them is a fine plant of R. Falconeri, a mass of bloom. R. Dalhousie is just opening its first buds, and in a few days it will be a sight worth going miles to see.—E.

Gesnera macrantha.—This is one of the brightest and most desirable medium-sized, winter-flowering stove plants grown. We noticed it the other day in the Kingston Nurseries beautifully in bloom; it seems to be a stronger grower than the old but still handsome G. Cooperi. It has larger foliage, stout short stems about 1 ft.

in length, and it bears on the top of each from twelve to twenty of vivid red, large, tube-shaped flowers. It associates well with other plants, and is very conspicuous at this season. A few examples of this *Geniera*, along with winter blooming *Begonias*, would make any stove look gay.—P. G.

Green Haricot.—We have received from M. Godefroy-Lebœuf specimens of a very curious variety of Haricot obtained by M. Chevrier. It is small, and has the rare merit of always remaining perfectly green. It is a heavy cropper, and, when cooked, found to be excellent.

Large-leaved Saxifrage.—These, which are more generally known under the name of *Megasea*, are highly decorative spring-flowering plants, particularly when they are treated as a speciality, as is the case at the Exotic Nursery, Tooting. Here are very fine examples of the many forms of *S. ligulata* in full beauty; one kind named *pulcherrima* more especially arrested attention, being very floriferous and of a delicate bluish tint. The hairy-leaved kind (*S. ciliata*) and its white-flowered variety are also in fine condition, and later on they will be succeeded by such rarities as *S. purpurascens* and *S. Stracheyi*, both very scarce Himalayan plants.—W.

Seedlings of Iris Kämpferi.—Mr. Barr has added to his collection of Irises the whole of Messrs. Von Siebold & Co.'s stock of seedlings, consisting of selections from the best types of double, semi-double, and single varieties of *Iris Kämpferi*, and as it is his intention to distribute these plants at once, a good opportunity is offered of securing some fine varieties which may reasonably be expected to exist amongst them. Mr. Hovey, whose arrival in this country we announced the other day, states that some of the varieties which he has recently grown are truly magnificent, both as regards colour and size of flower.

Orchids at Garibaldi Villa, Tottenham.—The following have been, and still are, beautifully in flower, viz.:—*Cattleya Trianae*, C. Mendelli, C. Mossiae, and C. amethystoglossa; *Cymbidium Mastersi* and C. eburneum; *Cologyne cristata* and C. speciosa; eighteen kinds of *Lady's-slippers* and as many *Dendrobies*; *Dendrochilum glumaceum*; *Epipedendrum aurantiacum*; *Vanda Cathcarti* and others; four kinds of *Lælia*; *Saccolabium premorsum*; *Renanthera matina*; various *Masdevallias*, *Phalænopsids*, and *Odontoglossums*; *Sophrontitis grandiflora* and many others. Of these the *Phalænopsids* are bearing scores of fine spikes; the *Odontoglossum* house is also very gay, and the *Cattleyas* will be at their best in about a fortnight. The plants altogether look well, and have maintained a fine display all through the winter.—H. C.

Crocuses at Tooting.—At Mr. Barr's grounds we were agreeably surprised to find a good clump of the new and rare *Etruscan Crocus* (*C. etruscus*) flowering freely amongst many other choice kinds. The flowers, which are purple with faint stripes and sweet-scented, associate well with such varieties as *C. banaticus*, a fine dark kind, the delicate *C. Weldenii*, and the various forms of *C. sulphureus*, the most conspicuous of which are striatus, feathered with dark stripes; concolor, of a uniform pale yellow; and lacteus, of nearly a cream colour. A variety somewhat resembling *C. stellaris* being of a pale yellow, heavily pencilled with black on the outside, and a bright golden-yellow within, is very attractive.

Flower Shows at the Crystal Palace.—We have received a copy of the schedule of prizes offered for competition at the summer exhibition to be held on May 21. There are thirty-two classes altogether, and only first and second prizes are offered. In conjunction with this is a list of the prizes offered by the National Rose Society for competition on June 28.

The Spotted Hellebore (*H. guttatus*).—Among the rich collection of Hellebores at Mr. Barr's grounds at Tooting, we observed a remarkably fine form of the above. The flowers are as large as those of *H. niger*, spreading, nearly white, and each sepal very profusely spotted with dark purple. The sight of this handsome variety at once gives a clue to the origin of the copiously spotted hybrids that have lately emanated from the continental gardens, and with which, until lately, our acquaintance has been by means of illustrations only. Another very distinct kind is a bluish-tinted form of the Olympian Hellebore (*H. olympicus*), on which account it is decidedly superior to the original, which generally assumes a greenish shade.—W.

Orchids at Southampton.—Being at Southampton the other day and having a few hours to spare, I bethought myself of an invitation given me by Dr. Ward, more than twelvemonths ago, to call and see his Orchids should I be in the neighbourhood. It was a wretchedly cold day, snow was falling fast, and glad I was when I reached Dr. Ward's residence in Harland Place, facing the public park. Although cramped for space, Dr. Ward has sufficient glass structures to contain a very choice collection of Orchids—a perfect

multum in parvo. Here I found the choicest representatives from every country and their finest forms, from *Dendrobium Wardianum* to the best of the introductions of later years; such as *Odontoglossums*, *Roezlii*, *vestiarium*, &c., and all wonderfully luxuriant and healthy. Amongst plants in flower, I noticed some grand examples of *Lycaste Skinneri*, *Sophrontitis grandiflora*, *Lælia acuminata*, *Oncidium leucochilum*, *Calanthe vestita*, several forms of *Cypripediums*, *Odontoglossums*, *Zygopetalums*, and others, all showing abundance of flower spikes. Suffice it to say that I thoroughly enjoyed my short visit, and went away feeling thankful that it is possible to find here and there in one's travels an oasis, as it were, in the desert. Would that there were many such! Now that Orchids are so cheap, and cool house ones so easy to cultivate, is it not surprising that there are so few cultivators of them to be found. To the credit of Southampton, be it said, there are, I believe, several very excellent collections in its neighbourhood, whose acquaintance I had no time to make.—F. H.

Gardening (Illustrated).—This is a cheap new weekly paper, intended to meet the wants of small cultivators. All who enjoy the charms and the healthful and profitable advantages of gardening must wish these to be extended to every owner or occupier of even the smallest patch of land. Happily for most of us, the pleasures of a garden have little relation to its extent. In so far as they have, the advantages seem to be in favor of the smaller class of gardens. Many an amateur cultivating his own garden out of business hours is happier in it than he who is waited upon by a dozen gardeners. Good health and pleasure can be secured by the busy man in no way better than by gardening. Advanced as our horticulture is, much yet remains to be done: Markets and large cities to supply with the best hardy fruits; the land made to double its present produce; the worthless kinds of fruit with which the greater number of small gardens and orchards are stocked have to be removed and replaced by first-rate varieties, hardy enough to grow anywhere; the great variety of delicate vegetables now existing have to be made popular, so as to be a useful aid to our present food supplies; and there is room for vast improvement in all that concerns the embellishment of the outdoor garden throughout the year with plants hardy in our climate. The aim of *GARDENING (Illustrated)* will be to help forward progress, especially in the smaller class of gardens, and to so treat the various subjects dealt with in its pages that its words may be understood by all who read.

THE floral decorations at Windsor Castle on the occasion of the marriage of His Royal Highness the Duke of Connaught, were on a very extensive scale, and were most tastefully arranged by Mr. Jones, the head gardener at Frogmore. Messrs. Veitch and Sons had the honour of presenting the bridal bouquet, and Her Majesty and the Crown Princess of Germany also accepted bouquets from Messrs. Veitch.

THE KITCHEN GARDEN.

DALMAHOY POTATO.

I SHOULD not have thought so much misapprehension existed with regard to this Potato, as the letters of "A. D." and Mr. Baines seems to indicate; allow me, therefore, to supplement my brief note (p. 225) by a few more particulars regarding the Dalmahoy, as it is to be regretted that any uncertainty should exist regarding a Potato every way excellent, except, perhaps, that it is not one of the best disease-resisting kinds. It is an enormous and even cropper, equal, in my opinion, to any other sort in cultivation at present, and the same may be said of its cooking qualities. It forms our main second early crop here, usually coming in in July, and lasting throughout August and part of September. It was raised twenty years ago, or perhaps more, near Edinburgh, and was named, I believe, after the place where it originated. For very nearly the period just named, it has, to my knowledge, been a favourite main-crop garden variety in the Lothians, and its merits were many years ago pointed out by Mr. Thomson, of Drumlanrig, who cultivated it extensively when at Archerfield, in East Lothian, where it was generally grown as a second early, and it has been more than once described by Mr. Thomson and others as such. In all the trustworthy Scotch seed catalogues it is described as a second early sort, and one of the best and large quantities of it are distributed by the Scotch houses, while the York Regent is described as a "late" kind. In Carter's list, where the different varieties are entered in their order of earliness the Dalmahoy comes in after the Early Shaw, and the Regent as one of the latest on the list. Mr. Baines' description of the two sorts would be pretty near the mark if he would reverse their names. He has just transposed the two. The Dalmahoy has the shallowest

eyes, in which respect it can be distinguished from the Regent at a glance. What has been extensively grown for a long time in Yorkshire as the Regent, and sold by those who claim to have the true variety is unfit to lift or use when the Dalmahoy is completely ripe and cooks like a flour-ball. The Dalmahoy is much smoother than the Regent in outline, and has also very much the shallowest eyes. Messrs. Ireland & Thomson hold stock of what is regarded as the true Dalmahoy by those who have been longest and best acquainted with it. J. S. W.

Potatoes worth Growing.—On first reading "A. D.'s" comments (p. 206) upon the sorts of Potatoes which I recommended for planting, I did not notice his statement that the Regent was almost certain to show a crop more than half diseased. This is incorrect; even in the worst of seasons, if the seed be properly prepared and planted in good time (which the great majority of people who only grow such a quantity as is required for their own use can without difficulty do), the crop will be ready for taking up before the disease makes its appearance; and even if half the produce were rotten, still the grower would be a great deal better off with one-half sound and of good quality, than with the whole of most of the worthless sorts year by year recommended at a high price. If the Regents be not worth planting, may I ask "A. D." how it is that the numbers of individuals who each grow hundreds of acres in the great Potato-growing districts still have at least three-fourths of their land occupied with Regents? The character which this best of Potatoes receives from "A. D." meets with direct confutation in nineteen-twentieths of the gardens and fields where Potatoes are grown throughout the kingdom. Those who choose to grow sorts that cost high prices for mere novelty have a right to do as they please, but it is quite time that the immense number of people who only want the best should realise the fact that there are none amongst the new kinds which surpass the old ones, and very few that equal them, notwithstanding the efforts made to push them forward.—T. BAINES.

—As I have grown all the sorts of Potatoes alluded to (p. 206) over and over again, and have satisfied myself as to the exactness of what I previously said concerning them, I prefer to abide by the Chiswick decisions, which were made only after opportunities of comparison such as no private grower could possess. Seed obtained from one locality may yield a crop either earlier or later than seed of the same kind obtained from another place, and thus lead to the inference that they are distinct kinds. Moreover, true stocks are not always sent out. At Chiswick, the stocks of each sort grown were obtained from several houses or localities, and the truest possible stocks were secured in every case. Mr. Legge is more fortunate than most growers with his Regents. All through this part of the country, where that variety has been grown by the hundred acres for market, the loss resulting by it was very heavy, and, in consequence, Magnum Bonum and Market Champion are taking its place. Out of several hundreds of bushels of various sorts sold retail during the past winter, positively not more than one gallon of Regents has been asked for. Those growers are, undoubtedly, wise who prefer to stake their hopes of a winter supply of Potatoes on some kind that will not give them a crop half rotten, let its sound remainder be ever so good.—A. D.

Magnum Bonum Potato.—Last season, at seed time, a sackful of Magnum Bonum Potatoes was sent to me, and they were duly planted; one row, 35 ft. long, across one of our rich garden quarters, and six rows in the field along with Patterson's Victoria, Regent, and Compton's Surprise. I lifted the single row on the 29th of August, and it yielded twenty-six stones of the very best Potatoes I ever saw, but I cannot say that they were the handsomest. The six rows in the field turned out a grand crop, but, if anything, more ugly than in the garden. I find Magnum Bonum to be a success, but compared with Lapstone it sinks into insignificance.—R. GILBERT, *Burghley*.

Scarcity of Green Vegetables.—Green vegetables have not been so scarce for some years as they are now. A farmer here has just commenced cutting Turnip tops for the London market. Although they are of poor quality, and are out with a large portion of Turnip attached to them, they have realised very high prices. As is often the case scarcity appears to intensify the desire for fresh vegetables, and the cultivator above alluded to is beset by applications by those who might easily have secured themselves against this dearth. Fresh, juicy Cabbages may be had the whole winter through, and a day's work for one man would suffice to provide for the wants of a small household. Supposing a good piece of Coleworts to be grown, they should, at the commencement of the winter, be laid in closely in a sheltered place, and if protected by a few boards or some litter, tender Cabbage may be had the whole winter through, no matter how severe the weather may be. I have practised this system myself

and know its value. I would therefore recommend it to the notice of those of your readers who may now be suffering from a scarcity of green vegetables.—J. COHNHILL, *Byfleet*.

Early Peas in Boxes.—For the earliest crop out-of-doors we use long narrow boxes made in 8 ft. lengths. They are merely strips of wood fastened together at the ends by means of tapering pieces of wood, and there is an extra piece in the centre for increasing the strength. These boxes have no bottoms, but strips of turf are laid in them to retain the soil. The latter is about 2 in. deep, and the Peas are sown in it in January. By the time they are ready to transfer to the open border in the end of February or early in March, they will be found to have rooted through the turf. They are at once staked, and evergreen branches are placed at close intervals to break the current of harsh winds. I may add that the boxes are 4 in. wide at the bottom, 6 in. wide at the top, and 4 in. deep. In planting, a trench is taken out and the box is set in it. After such a winter as the past, I find that by this mode of treatment a good start is obtained over Peas sown out-of-doors in November. The latter, as a rule, are gappy and very much cut up.—J. G.

Veitch's Protecting and Grange's Cauliflower Broccoli.—The past winter has been very destructive to Broccoli crops generally, and kinds that usually come into use in autumn are only now becoming fit for table. We have lately been cutting good heads of Veitch's Protecting, a kind that in ordinary seasons would have been fit for use at Christmas; also Grange's Cauliflower Broccoli, a very good sort. It is rather singular how these escaped, while many of the late sorts on the same quarters are killed. Their heads were partially advanced before the frost set in, and they were frozen as hard as stone for weeks, yet the thick covering of foliage and gradual thawing under an entire absence of sunshine saved the remnant of the crop. It is somewhat singular that Cabbage plants, even in the seed beds and protected from the severest weather by a covering of snow, are more cut up than the Broccoli.—J. GROOM, *Maidstone*.

Spade Hoes.—The illustration (p. 205) pretty nearly represents a very useful garden implement in daily use in Kentish gardens; we call it a mattock hoe, as it answers the purpose of hoeing, grubbing up roots, and digging at the same time; in fact, as "I. O. U." remarks, although a rude and simple-looking implement, it is surprising the variety of uses to which it may be put. Here the land is stiff, and orchard and garden crops necessitating a good deal of traffic on the soil, light tools so useful on light sandy land are comparatively useless, therefore tools of great strength have to be provided, and the spade or mattock hoe is invaluable, as it cuts up the softest weeds or the stoutest snickers with equal facility. Another Kentish tool for breaking up or trenching land, or digging hot gardens or orchards, is the "spud," or three-tined fork, the size and weight of which would alarm those accustomed to use Park's light steel forks, but which the labourers here prefer to a spade.—J. GROOM, *Linton*.

ANSWERS TO CORRESPONDENTS.

Laurels Turning Yellow.—My Laurels are planted on a chalk bank, with a south aspect, in about 2 ft. of good soil; nevertheless, they turn yellow, a circumstance for which I cannot account, and I should be glad of information on the subject.—B. C. W. [The chalk subsoil is the cause of the change of colour, and there is no remedy except digging out the chalk to a much greater depth, and replacing it with soil free from calcareous matter. Why not substitute Box for Laurels? Box flourishes on the driest banks and in the most chalky soils.—W. W.]

Soil for Cucumbers.—I have a Cucumber house heated with hot water pipes. What soil suits the growth of Cucumbers best?—SUS. [A loam of medium texture that is neither heavy nor light suits Cucumbers best. It should not be broken up into pieces of less size than that of fowl's eggs, as then the fibre is more lasting. Add to every 9 bushels of loam one bushel of horse manure and half a bushel of charcoal pounded into bits the size of marbles. Thoroughly incorporate the whole together, and when making up the bed press the soil moderately firm.—W. H.]

Crocuses after Flowering.—What is best to be done with Crocuses and other bulbs when done flowering.—A. S. [Plant them out in mixed flower borders. Do not cut off the stems, but let them decay naturally, they may then be expected to flower fairly well in open borders next season. Bulbs are so cheap, and flowering them in pots a second season so unsatisfactory, that it is not worth the trial.—W. W.]

Flowerless Stephanotis.—In the autumn of 1877, I planted a strong plant of *Stephanotis floribunda* in a narrow border at one end of a lawn to plant stove, 25 ft. long. It made considerable growth last season, which was carefully trained to three wires on the back wall, near the top. These growths reached the other end of the house by the end of the season, but produced no bloom, with the exception of one solitary small truss. Growth has again commenced, and shoots as thick as a quill are already 3 ft. long, but there is no sign of bloom. Have I got what is called the flowerless variety? A word of advice from some of your Correspondents would be very acceptable.—H. H. [I have had numbers o

Stephanotis from different sources, but I never have met with one of the so-called flowerless varieties, although I have seen a good many fail to bloom through not receiving the treatment which they required. A back wall, such as that described, is a bad place for *Stephanotis*, which wants all the light possible and sunshine as well, so far as that can be admitted without scorching. If much or fixed shading has been used on the roof of the house, the plant will be all but certain to fail as regards flowering. Unless the extending shoots, which sometimes run to a considerable length before producing any bloom buds, show blossoms in a week or two, I should recommend the plant being cut back to half its present length, and, if possible, the head and the shoots that will be formed during the summer should be trained on wires close under the roof glass over the front path in the house, if such exists. Use as little and as thin moveable shading as is consistent with the non-scorching of the other occupants; the *Stephanotis* likes a drier atmosphere and more air than the generality of stove subjects. Where the conditions above pointed to are absent, it never gets sufficiently ripened to bloom more than sparingly. —T. BAINEs.]

Evergreen Hedge.—A. P. G.—If the soil be suitable, nothing will answer your purpose better than Holly.

Goat Moth.—“W. C. B.” (p. 226) may easily rear the goat moth by confining it in a large flower pot, or some other vessel, placing a little earth at the bottom, and giving it a small log of Oak to eat. The perfect insect comes out about the end of June; it does not remain long in the chrysalis state. It is useless to put it in a wooden box, as it can easily eat its way out. —Geo. WALL, *Lake, Sandown, Isle of Wight.*

Librarian Coffee Seeds (p. 227).—The germination of these depends entirely on the condition of the seed and good, they vegetate in about a month or six weeks, if sown in a temperature of from 70° to 85°. The plants should be grown in a similar temperature, and cultivated the same as any ordinary hothouse plant; there is nothing special in their cultivation. —B.

Pathways for Peach Houses.—“Welshman” (p. 132) will find lattice footpaths the most suitable. We have them here made with four Oak rails 3 in. wide and each 1½ in. thick, nailed on cross bars 1 in. apart, they make capital pathways. Stone paths in any fruit house are never good, as the soil cannot be watered underneath them. —CAMBRIAN.

Seeds for Binding Sand.—Will some one be kind enough to advise me as to what kind of seeds will germinate and grow best in pure sand banks along the sea shore? This is a question of much importance in many localities, as sand blowing on to the land becomes a heavy loss. Last year we sowed six bushels of Broom seed on the sands, and harrowed it in like Grain crops, but it failed to grow. —CAMBRIAN. [Seeds, we fear, will not vegetate. Roots of “Sea-hens” are best for covering sandy stretches and arresting drifting sand. —G. B.]

Dead Tops of Pampas Grass.—I have three large plants of Pampas Grass with tall killed by frost. Would it be safe to burn off the withered Grass as is done on the prairies of America? It would be difficult to cut them down as they are a mass of stems, and have not been cut for years. —O. W. D. [It would undoubtedly injure Pampas Grass plants to burn off their dead leaves. The dead Grass should be cut off with a knife. A good thick layer of well-rotted manure dug in, round, and over the roots of such plants would be very beneficial to them. —G. B.]

Pansies for Exhibition.—Kindly give the names of twelve of the best Pansies for this purpose. —F. P. [The following are a few of the best show kinds:—Captain Cowan, deep golden yellow, belted with bronze purple; Dr. Gibb, cream self; George Murray, pure yellow self; Undine, white, with a very light purple belting; Olio, deep yellow, with a light purple belting; Gaby, rich dark self; Mrs. Reid, white, with a very light purple belting; Alpha, pure white self, with a distinct dark blotch; W. Forbes, dark self; John Halliday, rich yellow, belted with maroon; Mrs. Russell, light yellow, belted with broazy purple; Favourite, white ground, violet purple margin; Mrs. Henderson, white, with a light purple margin.]

Roses and Gishurst Compound.—I have some very good free-growing Roses of various sorts, climbing over some rough wooden palings about 8 ft. high. Some of them were quite spoiled last year, and nearly so the year before, by red spider. I wish to try “Gishurst Compound” as a remedy, but fear that if I apply it by syringing freely and strongly enough to kill the red spider, I may so impregnate the soil with the “Compound,” as to kill my Roses and other plants. Will any of your readers tell me whether I need fear this, and if not when I had better syringe my Roses, and what strength to use the “Compound.” —TEGAFA. [Gishurst Compound will do very well as a winter dressing for Roses, and no fear of its injuring the roots need be apprehended if it be used according to the directions that will be found on the box containing it. Well syringe every crevice of the palings as well as the Roses. The best preventive of red spider is to manure the ground freely, and keep the Roses well watered; once let the border get dry and the foundation is laid for the attacks of this pest. Every evening in dry weather well syringe the plants with clear water. —W. W. H.]

Peach Trees and Galvanised Wire.—I should be greatly obliged if any of your experienced readers could explain the cause of my Peach trees becoming black and the bark going to decay at the exact part where they touch the galvanised wires? They have been planted two years, in a small house without artificial heat, and are now full of bloom buds, but since the sun begun to shine they show symptoms of suffering in all cases beyond the damaged part. I have also on a portion of the back wall, and trained to the same kind of wire, a Jossamine, which is

alike damaged. Is this usual? and can it be prevented without taking down the wires? If not, what should I do for the best? and should the alteration be made at once, or should the trees be left alone this season? —J. WOOD, *Woodville House, The Spring, Kirkstall.* [Though some cultivators denounce galvanised wire and believe it to be injurious in the manner indicated, you need not get alarmed or think that you must take down the wires. Simply the stalker, so as to allow sufficient space for the expansion of the wood. We have galvanised wire trellises in two of our Peach houses, yet a branch never dries, and full crops of fruit have been obtained regularly for many years. —H. W.]

Insects.—J. G. Henly Hall.—Of your four grubs two are the grubs of the beetle, *Otiorynchus sulcatus*, well known for the injury which they do to the roots of plants; the other two are pupæ of some hymenopterous insect. The four are much alike in size and colour, but are very different as the slightest examination shows. You should destroy as many of the grubs as you can to prevent them getting into the perfect state, and so prevent increase. —W. W. S.

Work on Castor-oil Plant.—R. P.—We know of no such work on the Castor-oil plant. We presume you mean its culture in the Tropics. In this country its culture is very simple, and is described in the “Sub-tropical Garden.”

Names of Plants.—J. R.—Apparently some seedling form of *Rhododendron Dalhousiae*. C. M. O.—*Primula denticulata*, or some slight variety of it; *Viburnum lucidum*, *Pteris longifolia*, and *Andromeda calyculata latifolia*. P. J. N.—Seems a small shoot of the Carob tree (*Ceratonia Siliqua*), but with such a specimen it is difficult to say with certainty. *Widia Lapageria*.—It is a much newer and rarer plant, and the stock in the country much less; therefore, it is more expensive. *South Wales*.—Seems to be part of a leaf of *Lardizabala biterata*. In South Wales it should form a fine wall climber.

ROSES.

WINTER AND SPRING FORCED ROSES.

The method of forcing Roses given in detail by M. Lachauxme (p. 204) differs materially from that practised in this country, especially by the best growers of these flowers for the London market. In France it appears that small plants are mostly grown one season in pots and then forced, the heat by which they are brought into flower in the case of such as are forced in frames being derived from fermenting materials alone. In France the plants seem to be grown in comparative darkness, but in England we are of opinion that plenty of light is conducive not only to the production of large flowers, but in the case of pinks, reds, and yellows better colour; and flowers produced by plants so treated keep longer fresh than when they have been grown with less light. Nor is this all. The Rose growers in this country find that by subjecting their plants to a maximum of light whilst being brought on into flower they grow on and increase in size and strength from year to year; whereas if forced in darker situations they improve but little, even if no absolute deterioration takes place. The advantages of the plants getting stronger and larger are manifest as the flowers borne by such are, in the aggregate, much larger than those from small plants, a circumstance which makes a material difference in the prices which they realise, as full-sized blooms fetch the double the money small ones do. Anything in the shape of fermenting matter in the houses in which the plants are forced is now excluded by those whose flowers are held in the highest estimation by the buyers, for, as might be supposed, everything of this character tends to the production of a soft, flabby, texture in the blooms, thus rendering them less durable and, consequently, less valuable.

The houses which have in recent years been erected, and which are still being largely added to, are made to admit as much light as any combination of glass and wood can possibly do. The glass in most cases is from 18 in. to 20 in. wide, and the bars which hold it are as thin as they can be, considering the weight they have to bear; they are, however, strengthened by a proportionately light bar, placed beneath them transversely midway between the eave and ridge, and which at short intervals is supported by light iron or wood uprights. Not only is the roof thus made so as to intercept no more light than can be avoided, but the sides and ends are often glass right down to within a few inches of the ground. Such are the Rose houses now being built by the market growers in the neighbourhood of London, and which in many cases have another peculiarity; viz., the extremely small provision made for the admission of air through the autumn, winter, and

spring; in fact, for nine months out of the twelve. To such extremes is this being carried, as to quite upset much that has been written in regard to ventilation in plant-houses of all kinds. But when we see such a course pursued by people who have been years engaged and are most successful in growing this particular flower, in a way that gives the best return for the outlay incurred, and when, in addition, we see the plants go on year after year improving in size and ability to produce larger quantities of the finest flowers, it becomes evident that all has not been learned which is possible on this important subject. It is, in fact, a confirmation of what I have long observed, and also urged, in the cultivation of by far the greater number of the plants that require, or are grown in, heat, viz., that the more light we can give them the less air they need. There is immeasurably more mischief done by the admission of too much external air than there is in the opposite direction, to say nothing of the waste in fuel when the internal air of the structures in which plants are grown is warmed so as to necessitate the ventilators being opened to let it out. The subject, however, is one which needs to be approached with caution. Those who attempt to grow plants in heat, and with a minimum admission of air in dark houses, or such as do not admit the full complement of light, are almost certain to fail. Insufficient light and little air will not do together. Where there is a minimum of the former, there must be a maximum of the latter in the case of plants cultivated in heat.

T. BAINES.

CENTAUREA RAGUSINA FROM SEED.

It will be years before we shall get a bedding plant likely to be capable of superseding this. It is so striking in appearance, so compact in growth, and so useful in various combinations that it is almost without a rival. Its glistening silvery foliage contrasts well with such plants as *Lobelia speciosa*, purple and violet *Petunias*, *Verbenas*, *Gazania splendens*, &c., and it remains good right up to the end of the summer. One good quality about *C. ragusina* is, that no amount of rain disfigures the plant in the least; the leaves retain their colour under all circumstances. Some find it difficult to propagate by means of cuttings. This is obviously the best method of keeping up a stock of a good, compact variety (for seedlings differ in type), and a good plan to secure such a stock is to introduce some old stools of last summer's growth into a good brisk heat in February, at the same time depriving them of a great part of their foliage, and in a few days there will be plenty of young suckers and side-shoots, which, taken off with a small portion of the stem attached, inserted in a 2½-in. pot, and plunged in a brisk bottom-heat, will, in a few days, be rooted sufficiently to be potted off, which operation needs to be performed tenderly, as the roots are very brittle, and soon break. When the cuttings are repotted, they should be returned to warm quarters to establish themselves a little; they can then be gradually hardened off.

A short time since I sowed 500 fine plump seeds, sowing them in pans in a good, light, sandy soil, and placing them on a gentle bottom heat. Over 400 of them grew quickly, and the others are gradually showing through the soil. As soon as large enough to handle they will be pricked off into shallow boxes. The next shift will be into small sixty pots, and, if there is time and house space, they will yet have another shift. This is a rapid way of getting up a stock, and I find as a general rule that seedling plants are pretty uniform in character. At any rate, the seedling plants that show a tendency to grow tall should be planted out with tall-growing plants, or go in the centre of large beds, keeping the dwarfier-growing types for dwarfier associates. I have tried *Centaurea ragusina compacta* for bedding purposes, and confess to being disappointed. It is too dwarf for many combinations, and to my mind it lacks the chastened silvery hue that belongs to the older type. Such is my experience. Others may be more fortunate with it, but I can only state what has happened in my own case. To many the foregoing information may appear the reverse of new. Let it be remembered that the ranks of gardeners, and of amateur gardeners in particular, are constantly being renewed, and that there is, in consequence, no lack of learners. D.

Tritomas and the Frost.—We grow *Tritoma Uvaria* and other varieties extensively, as when in bloom they look well backed up by evergreens. After the frost first broke up, in clearing away decayed leaves and frost-bitten subjects, some of the *Tritomas* were partially divested of their weather-beaten leaves, and I find that these have suffered severely from succeeding frosts, while those left with their

old leaves intact are already pushing up vigorously. To Ferns and many other plants, the decaying leaves also form a natural and efficient winter protection.—J. G. L.

PROPAGATING.

GRAFTING DAPHNE INDICA RUBRA.—This is best increased in this way. Get the stocks into the propagating house early in March—say a fortnight before they are required to be grafted, in order that the sap may be in motion. With a sharp knife cut the scion, as shown in fig. 1, then the stock, as seen in fig. 2; bind tightly together with thread or matting, and put a small piece of grafting wax on the top (cut-off part) of the stock; set them on a cool bottom in the grafting box in

Fig. 1.—Scion of *Daphne indica rubra*.

the propagating house, and keep them close for a few days then give a little air every morning for a couple of hours. Under proper treatment they generally unite in about six weeks, when they may be gradually inured to more air, and removed to the greenhouse.—H. H.

Fig. 2.—Stock for *Daphne*.

Useful Paths for Forcing Houses.—There are so many fancy articles now-a-days in the way of tiles and other ornamental flooring, that some of the more serviceable but less showy materials get overlooked. For forcing houses or pits where a good deal of work has necessarily to be done, and where a smooth, hard surface that can readily be cleaned is a desideratum more than ornamental effect, I find nothing better than good cement laid on a good thickness of concrete or broken bricks. If applied about 1 in. thick and allowed to get thoroughly set and hard before it is trodden on, any kind of wheeling or even carting may safely be carried on on it, and it is very durable. A grating just outside the door, with a cesspool to catch any sand or soil that may be washed out of the houses, so that the water may run away without choking the drains, will be found a useful addition to any kind of glass structure.—J. G. L.

Hardiness of *Selaginella Kraussiana* and *S. Brownii*.—These have proved hardy with me this winter planted in an unheated house. They are now quite healthy and growing.—J. L.

Fine *Dendrobium Wardianum*.—Mr. Charles Hart, of Lea, sends us flowers of a remarkably fine variety of *Dendrobium Wardianum*, measuring 5 in. in diameter, and very finely coloured. It is pronounced to be the finest variety yet seen of this plant.

No. 384.]

SATURDAY, MARCH 29, 1879.

Vol. XV.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

EARLY FLOWERING SAXIFRAGES.

IN spite of cutting easterly winds, and the bleak wintry storms that still prevail, the group of Alpine Saxifrages, of which *S. oppositifolia* may be regarded as the type, display their charms here in a manner that seems almost out of harmony with the rest of Nature. The original typical form of *S. oppositifolia*, so common (and, perhaps, exclusively known) forty years ago, is now very scarce with us. Its rosy purple flowers are nearly circular, and form a mass of bloom so dense that the blossoms often overlap each other, and entirely conceal the foliage. The variety known as *S. oppositifolia* var. *splendens*, has flowers of much greater brilliancy, though slightly smaller. In bud, especially, the colour is almost carmine, and exquisitely beautiful. In density of bloom it approaches the typical form, but rarely quite equals it. This variety we obtained many years ago on the mountains of Scotland. *S. oppositifolia* major has flowers twice the size of the type, with less of the purple tinge. It is of a clear Rose colour, inclining to Cherry. The petals are broad and well rounded, but when fully expanded they are less compact than those of the type. The origin of this showy variety is unknown to me. *S. oppositifolia* pyrenaica differs conspicuously in habit. Its shoots are ascending (*i. e.*, erect at the tips), and are twice as robust as those of any of the preceding. The flowers also are larger, but usually more sparse. Perhaps its finest form is *S. oppositifolia* pyrenaica maxima, which has enormous blossoms (as large as shillings), of a lovely light rose colour. The inflorescence of this is often very dense. *S. oppositifolia* alba has, as the name implies, white flowers, which form a pleasing contrast to the other varieties; but, unfortunately, though the colour is good, the form of the alba which we grow at York is anything but good. It is narrow-petalled, and not compact in bloom. Should any one possess a snow-white, well formed, compact flowering alba, I should be glad to have some information respecting it.

S. Rudolphiana (Koch) has a more spreading habit of growth, and the rosy purple flowers are borne sometimes singly, sometimes (though rarely) in pairs. Its alliance is with *S. biflora*, the habit of which is loose, with clustered ascending tips. The flowers are in clusters of from two to four, varying in tints from bright rose to deep blood colour; petals narrow, and wide apart. *S. Kochi* is similar in habit to the last, but it has rosy purple flowers, also borne in twos and fours together at the extremities of the shoots; it is good in form, the petals being broad and close. *S. retusa* has foliage very short, firm, dense, and compact. Its flowers are small, and in clusters at the extremity of erect stalks; the petals are narrow, pale rose, sometimes brighter. It blooms rather later than the varieties of *S. oppositifolia*. *S. Wulfeniana* is closely allied to the preceding, of which it is probably the Tyrolean form. *S. Burseriana*, with its charming white circular erect blossoms, and brownish-red—sometimes almost scarlet—calyxes, contrasts grandly with any or all of the foregoing, and blooms at the same time, or even earlier; *i. e.*, as soon as the winter's covering of snow or ice melts off. This species forms dense circular cushions of compact erect branchlets, and is an invaluable early spring flower.

S. oppositifolia and its varieties flourish in open, rich, loamy soil, either in the common garden border or in fissures of rockwork; but, in either case, the soil should be trenched or prepared fully 2 ft. deep, so that the roots may reach a level below that which is affected by summer drought. They are perhaps the finest when placed in a fissure or on a ledge of rockwork, where the roots can ramble backward or down to any depth, the soil being rich, light loam, mixed with fragments of limestone or grit (small fragments of any rock will do), and a little river sand. They should always be placed so as to get sunshine; they grow but will not flower freely in the

shade. The same treatment, with a little admixture of peat or vegetable mould, suits *S. retusa* and *S. Wulfeniana*. The Tyrolean species (*biflora*, *Rudolphiana*, and *Kochi*) are less easy to please. They grow wild on the moraines of glaciers, where light vegetable soil, sand, and *debris* of every kind blend with massive rocks, now coating the surface, now filling the interstices; water dripping or oozing around, and frequently flowing in volume within 2 ft. or 3 ft., so as to soak the bases of the rocks on which their rosy carpet is spread. They will condescend to grow in pots, nevertheless, but rarely with the freedom which characterises the varieties of *S. oppositifolia*.

York.

J. BACKHOUSE.

PRIMROSES AS WINDOW PLANTS.

THE Primrose, both single and double, is deservedly a favourite garden flower, but its value as a pot plant for window decoration is not perhaps so well known as it should be. There is not the slightest reason why our dwellings should not be made gay with this charming spring flower at an earlier period of the year than it comes naturally into bloom in the open air. Primroses are impatient of forcing, but they flower beautifully in the window of a cool room, and expand their pretty bright blossoms as well, and oftentimes better, than when in the open ground. Nor are they particular as to aspect; according to my experience they thrive quite as well in a north window as in one more fully exposed to the sun. It is this latter quality which renders Primroses especially valuable, as we really find but few plants which, during February and March, will grow and flower freely in a north aspect. Many apartments, which at this season of the year present a rather dreary appearance, might be effectively and inexpensively enlivened by filling their windows with Primroses, and the most satisfactory part of the matter is that Primroses not only live there, but the owner has the pleasure of seeing them grow, expand, and develop fresh beauty every day. It lays in the power of every one to render their homes bright and pleasant in early spring by means of these ever welcome flowers. By planting them out during summer in good soil in a sheltered situation and keeping them well watered they may be lifted with good crowns and roots, planted in 4-in. and 6-in. pots, and stored away in a frame or in some sheltered spot where they can be protected during severe weather, from thence to be introduced—about the middle of January—into the situations which they are intended to beautify.

J. CORNHILL.

Byfleet.

Muscari lingulatum.—The rare, pretty, and very distinct little *Muscari lingulatum* has been in bloom with me for the last two weeks. It is the dwarfiest of the genus as far as I am acquainted, and the most distinct. The flower spike, which is a pale sky blue, rises from two short, strap-shaped leaves, which remind one more of a Tulip or *Bellevallia* than *Muscari*. The bulbs were sent to me by Mrs. Darford who collected them in the Cilician Taurus at the same time that she discovered *Crocus parviflorus*. With the *Muscari* Mrs. Darford sent me three or four bulbs of a *Scilla* allied to, but distinct from, *S. sibirica*. It flowers about a week earlier than the latter species, has blooms of a much paler colour, and is much smaller in all its parts. It reminds me of *Scilla sibirica* minor which appeared in THE GARDEN a short time since. It may be the Russian *S. amurensis*, but I know nothing personally of these two varieties. Mrs. Darford's *Scilla* is earlier than *S. bifolia nivalis*; in fact, it is the first of the family to bloom.—H. HARPUR CREWE.

Lesson from Nature.—I have often been struck with the beautiful effects which Nature with simple materials produces in landscape scenery. Here is an example which I saw last summer. A river meandered through verdant meadows, the banks of which were studded with Willows, Alders, Ash, and Brambles. These were sometimes in the form of single specimens or small clumps, and at other times expanded into dense masses of foliage, either formed of a single species or composed of various kinds. The foreground was carpeted with Forget-me-nots, and these again were backed up by masses of the purple Loosestrife and the large Willow Herb which sprang out of the dense foliage of a species of Sedge. Higher up tufts of the bright yellow Tansy lighted up the whole mass, whilst noble specimens of the Waterdock flanked it, and the lovely flowering Rush issued here and there from the water itself. A few Willows and Alders in the background completed the picture. Effects such

as these are easily obtained, though not necessarily by means of the plants just named. There is, happily, a wide field for choice in this respect; there are many noble plants that are well adapted for, and which might be utilised for this purpose.—JOHN CORNHILL, *Byfleet*.

NORTH AMERICAN HARDY PLANTS.

We have received from Messrs. Woolson & Co., of Passaic, New Jersey, U.S.A., catalogues of North American plants, bulbs, &c., very interesting on account of what they enumerate, and very correct as regards nomenclature, &c. The list devoted specially to North American roots, bulbs, &c., is one in which will be found many beautiful plants of North America offered for sale for the first time. In this American catalogue occurs not a few plants very common in Europe, even in a wild state, but also many which have not as yet been introduced to cultivation here. There is a separate list of North American Ferns, not without value to those who wish to enrich their collection of hardy species, and also a list of North American Orchids. We have reason to believe that the nomenclature of the plants offered by this firm is correct. The following are a few of the plants enumerated:—

AMIANTHUM MUSCETOXICUM (Gray).—A smooth, bulbous plant 1 to 2 ft. high, with broadly, linear leaves, and a simple, dense raceme of handsome white flowers, which turn green with age. Flowers and foliage both showy. Does best in a rather moist, sandy soil. New Jersey and southward.

ANDROSCEPHALUM BREVIFLORUM [Watson].—Utah. Flowers violet, borne in umbels of four to seven, in early spring. A stouter plant than the next, and with smaller flowers. New and rare, and as yet but little cultivated.

ANDROSCEPHALUM VIOLACEUM (Torr.).—A rare and showy species from Texas, 6 to 8 in. high, with a small, coated bulb, which surmounts a depressed globose bulb or corm. Flowers violet, borne in umbels, slightly fragrant.

ARISEMA TRIPHYLLUM (Torr.).—An aroid, 12 to 18 in. high from a Turnip-shaped corm. Spathe green, or often variegated with dark purple and whitish stripes or spots, and much hooded at the summit. Commonly known as "Jack-in-the-Palpit." An interesting and showy plant for moist places.

BRODIAEA GRACILIS (Watson).—New species; California; 2 to 4 in. high; dwarf, with small yellow flowers, with brown mid veins.

BRODIAEA MULTIFLORA (Benth.).—Oregon; 1 to 2 ft. high; flowers blue; leaves 1 to 1½ ft.; fleshy; bulb 1 in. or more in diameter resembles *B. congesta*, but distinct.

CALOCHORTUS AUREUS (Watson).—Southern Utah; a dwarf species 4 to 6 in. high, with flowers 2 to 3 in. in diameter, of a deep, rich yellow; petals bearded and furnished with purple spots at the base; recently described and still rare.

CALOCHORTUS FLEXUOSUS (Watson).—Utah; branching, with greenish orange-spotted sepals and purplish petals, deep purple at the base, and a circle of orange or purple above; flowers 2 to 2½ in. across; new and rare, and but little known in cultivation.

CALOCHORTUS GREENI (Watson).—New species; Northern California, Oregon, &c.; 1 ft. or more high; flowers large lilac, barred with yellow and purple; new to cultivation.

CALOCHORTUS GUNNISONI (Watson).—Rocky Mountains, &c.; one of the finest and, at least with us, most hardy species. Stem 6 to 20 in. high, bearing one to four flowers, the petals of which are white above, yellowish-green below the middle, dark purple at the base, and strongly bearded.

CLATYONIA TRIPHYLLA (Watson).—Oregon, California, &c.; stems from deep-seated tubers; flowers in compound racemes, white or pale rose colour; not before offered.

COOPERIA DRUMMONDI (Herb.).—Texas; a bulb belonging to the *Amaryllis* family, with slender, linear leaves and a naked stem, which bears at the top a single, fragrant, white flower 1 in. or more across, with a slender tube 5 to 6 in. long; an excellent plant for forcing; this is hardy in our grounds.

COOPERIA PEDUNCULATA (Herb.).—Texas; flowers white, opening at night, and very fragrant; differs from the above in having a green tube and longer and broader leaves.

CRINUM AMERICANUM (American Crinum).—Florida; 1 to 2 ft.; a rare and showy bulb which may be planted in the open ground during summer; flowers large; 6 to 8 in. long, very fragrant; similar in habit to *pancratium*, but without the crown on the tube of the flower.

DELPHINIUM SIMPLEX (Dougl.).—Oregon and northward; 12 to 30 in., bearing dense racemes of flowers, which vary from blue to almost white or yellow. This species of *Delphinium* is tuberous.

*ooted, and drops its leaves soon after flowering; the tubers, after overwintering, may be kept in dry sand, like *Dahlia* roots.

DICENTRA UNIFLORA (Kellogg).—Sierras of California, southward stems 3 to 5 in. high, from a fasciculate fleshy root, surmounted by a bulb-like cluster of grain; flower-scape one-flowered; petals flesh-coloured; we believe this is new to cultivation.

ERYTHRONIUM ALBIDUM (Nutt.).—White Dog's Tooth Violet.—Iowa and other Western States; flowers purplish white, and leaves not generally spotted; a fine showy species.

ERYTHRONIUM PURPUREUM (Watson).—A new and recently described species from California; flower stems low, stout, and bearing four to eight flowers, which are light yellow, more or less tinged with purple, and deep orange at the base; very distinct from the last.

EUSTYLIS PURPUREA (Engelm. & Gray).—A beautiful plant belonging to the *Iris* family; flowers of a deep purple, borne on stems 1 ft. high; fine for forcing.

FITILLARIA ATROPURPUREA (Nutt.).—Sierra Nevada and northward; stem 4 to 24 in. high, and bearing one to nine flowers, which are dark brown, variegated with greenish white or yellow; both leaves and stems are generally tinged with brown or purple.

FITILLARIA PUDICA (Spreng.).—Oregon, Utah, &c.; a pretty dwarf species 3 to 8 in. high, and bearing one to six deep yellow, bell-shaped flowers in early spring; one of the easiest to grow.

FITILLARIA RECURVA (Benth.).—California; 1 ft. or more high, with flowers 1 in. long, blotched scarlet and yellow; very fine and showy.

HABRANTHUS ANDERSONI (Herb.) var. *TEXANUS*.—Texas; a beautiful dwarf *Amaryllid* with narrow leaves from small obovate bulbs; stem one-flowered; flowers 1 to 2 in. long, yellow or copper coloured, striped externally with reddish veins; fine, and not offered before, we believe.

HESPERALOE YUCCAFOLIA (Engelm.).—Texas; this, which has been styled the "Red-flowered Yucca," grows 4 to 5 ft. high, with numerous red, cylindrical, bell-shaped flowers, which look more like those of *Aloe* than *Yucca*; a very rare plant which has seldom been under cultivation.

HESPEROCHIRON PUMILUS (Porter).—Oregon, &c.; a dwarf, stemless plant 2 to 4 in. high, bearing in early spring single purple or purplish white flowers, which are densely bearded within; this is *Villarsia pumila* (Dougl.).

LEWISIA BRACHYCARPA (Edgelm.).—Utah, Sierras, &c.; a species new to cultivation so far as we are aware; the leaves are fleshy, spatulate or linear in rosettes; flowers white, 1 in. or more in diameter, with seven to nine petals, and very showy.

MERTENSIA OBLONGIFOLIA (Don).—Oregon, &c.; 6 to 8 in.; this is one of the most showy and desirable Alpines for earlly spring flowering that we have cultivated; the flowers are deep blue in close clusters; it has proved perfectly hardy with us for several years, having stood our cold winters without protection.

PANCRATIUM ROTATUM (Ker.).—Florida to North Carolina; 1 to 2 ft.; flowers large, white, fragrant, with beautiful fringed coronas.

STENANTHIUM OCCIDENTALE (Gray).—Oregon; a rare Liliaceous plant, which we believe we are the first to offer; stem 6 to 24 in. high, bearing greenish-purple flowers, which have recurved, yellowish tips, and are borne in a raceme or simple panicle; individual flowers ½ in. or more long; this has somewhat the habit of *Camassia esculenta*; grows naturally upon the Mossy banks of mountain streams, and, our collector writes us, is scarce.

THILLIUM PETIOLATUM (Pursh).—Oregon, &c.; the most remarkable of all the N.A. species; leaves large, cordate, with long petioles; flowers large, sessile, purple.

In a Somersetshire Garden.—The annexed engraving shows a portion of a rock garden at Orchardleigh Park, on which the hardy Palm is quite at home, grouped with *Yuccas* and *hardy Ferns*. Near the same spot, but not shown in our sketch, the *New Zealand Arundo* and the *Pampas Grass* attain unusual dimensions. These and such as are shown in the engraving are bold and varied types of exotic plants hardy in most districts, but particularly free and vigorous in this western county.

Balanitum Culcita.—This, one of the most useful of Ferns, has the large spreading fronds of a *Dicksonia*, without its stem. We have some large clumps of it growing on elevated rocks in our Fernery, and, in addition to its being one of the noblest looking of Ferns, it is eminently suited for cutting, the fronds being subdivided so that the sprays are available for many kinds of decoration, and of a most beautiful deep glossy green, a colour which they retain for a very long period. Any one having a cool Fernery, and desirous of having a rival to the well-known *Woodwardia radicans*, should try this noble Fern, which I feel sure will give satisfaction.—J. G., *Linton*.

PLANTING THE SIDES OF CARRIAGE DRIVES.

In addition to the Rhododendrons which "Beta" (p. 132) proposes planting along the sides of his carriage drive, groups of gold and silver Hollies would have a capital effect, but, in order to show these off to the best advantage, clumps of the common kind or some other dark evergreen should be planted between them. It is best, however, to use the same species, as then they associate well together, and a good way of arranging them is to plant alternately at wide intervals, when part of the space between may be filled with irregular beds of Rhododendrons, groups of *Arundo Donax* and conspicuous Bamboos, Pampas Grass, and such like, which will render the drive both ornamental and interesting at all seasons. Similar effects may be produced by using the common and variegated Yews, but, being so much slower growing than the Hollies, it would take many years to get them of large size. One of the brightest and best of the golden Hollies is Lord Harrington, which, in good rich soil, grows at a great rate, and soon forms a very handsome specimen. Before planting the best way is to break up the ground to a good depth by trenching it thoroughly over, and, when doing this, to work in plenty of rotten manure, together with the trimmings from the sides of roads and the scrapings of the same, a mixture that Hollies greatly delight in. These shrubs can only be transplanted with safety about the first week in April, or just as they are bursting their buds, a time when there is a reciprocal action below, thus enabling them to start off into growth at once before the bark becomes shrivelled and contracted, from which they seldom recover. A heavy mulching with a thorough soaking of water at the time of planting will help to prevent this, and be of great service in enabling them to become quickly established. Irregular-shaped clumps will be found to produce the best effect, as being less formal, the outline viewed from any particular spot is sure to be more pleasing and satisfactory. As the soil is of a sandy loam, it will suit all the plants enumerated above, Rhododendrons included, unless it happens to contain calcareous matter, which if it does, these shrubs will refuse to touch it, as they have a strong dislike to anything of that kind. Sharp grit they are very fond of, and, like the Hollies, greatly appreciate any trimmings from the roadside, which if mixed with refuse peat, or thoroughly decomposed leaf soil, answer famously for giving them a start. Assisted in this way, I have known of several instances where they succeed and flower better than when they get all peat, which is accounted for by the more rapid manner in which the latter decays, and the shallower level the roots ramify in when they have little else but vegetable matter to feed on. Although Rhododendrons object to much manure in the soil, it is of great benefit during hot, dry summers if laid on the surface, as then the juices are washed out and carried down, and the dense shade it affords keeps

the ground cool and intercepts evaporation, at a time when moisture is of the greatest importance in assisting them to form their young growth and stud it with flower buds. The margins of the Rhododendron clumps or the vacant spaces between the plants will come in admirably for planting different kinds of Lilies, the soil and situation there being specially adapted for their successful culture, as, to grow them well, it is essential that the bulbs should be in soil on which the sun does not shine hotly, although the tops will bear almost any amount. This they will get in abundance as they peep up amongst the

shrubs, the foliage of which is a great help in showing off the gorgeous beauties of the flowers to the greatest advantage. Most of the Lilies are supposed to do best in peat, but the finest *L. auratum* which I ever saw was growing in a mixture of leaf-mould and roadside trimmings in about equal proportions, the latter of which contained a good deal of sharp washed sand, that appeared to suit the bulbs remarkably well, as they increased in size at a great rate, and each year grew finer and stronger. The hardiest of the Bamboos is *Bambusa Metake*, the habit and general character of which render it just the thing for associating with the *Arundo* or the Pampas Grass, magnificent groups of which may be formed separately or mixed in large masses, the effect either way of the whole, seen in such striking contrast with the more round-headed shrubs, being such as to break up the uniformity and give a more natural appearance. The point in planting is to leave plenty of breadth of Grass between the several masses, as nothing adds so much in heightening and giving finish to the whole as a large expanse of turf, the tendency unfortunately of late years being to curtail this, and thus English gardens and grounds are robbed of much of their beauty. Very ornamental clumps may be made in the paddocks adjoining by planting the White Poplar, or Abele, and Copper-leaved Beech, the silvery leaf of one and the dark rich colour of the other being very telling from early spring to autumn, and, as they are both tolerably fast growing, there would not be long to wait before getting them to a fair size. Among the Pinuses, none, in my opinion, forms more picturesque groups than the Scotch Fir, the polished bark of which and the quaint heads the trees form as they attain age giving them quite a tropical appearance. Among deciduous trees *Liriodendron tulipifera* is one of the most ornamental, as is also the Plane; both have very large, finely-cut leaves that colour up well in the autumn.

S. D.

In a Somersetshire Garden.

Glossy-leaved *Laurustinus*.—This acquires here a very large size and generally blossoms profusely, though somewhat later than the common kind. This year, however, though both are covered with

flower buds, I fear the frost has injured the buds too much to allow of the n flowering well.—C. M. OWEN, *Gorey, Ireland.*

THE KITCHEN GARDEN.

VEGETABLES *v.* FRUIT.

IN the discussions which take place from time to time on the subject of growing fruit in this country with advantage to the consumer and profit to the cultivator, it seems to me that the question of providing a good and cheap vegetable diet is very much overlooked. When people can buy oranges for months in the year at two a penny, eatable foreign Grapes of much better appearance than those often sold in Covent Garden at high prices, for 4d. and 6d. per lb., Apples, Pears, Plums, &c., at prices which just leave the lowest margin of profit to the grower and retailer, or makes it worth his while to carry them to the market, I do not think they can complain so greatly, but in the matter of salads and green vegetables how do the masses of the people in the great centres of industry stand? Why, they have simply to do without them; firstly, because after supplying themselves with the other necessities of life they have little to spare on vegetables, and secondly and principally, because vegetables are too expensive and uneatable. The general arrangements in most of our large towns where vegetables are most needed, for the distribution of marketable garden produce, are, as a rule, simply execrable. The general public cannot conveniently procure what they want except through the middlemen or greengrocers, and it does not appear that the latter can sell remuneratively under a figure fifty or a hundred per cent. above what they pay for their goods in the market. This, to my knowledge, is exactly the state of things in some of the largest towns in England. Why, in some of these towns, you might count the respectable greengrocers' shops on the fingers of one hand, and these cater for the wealthy principally. Go into the market on any day and see if you can buy even a head of Curled Greens with more than a mouthful of wholesome or cookable leaves on it for less than 1d. or 2d. each; three small sticks of Rhubarb for less, when it is plentiful; a stick of Celery under 3d.; a Cucumber under 6d. or 9d. in season, or any other common produce at a reasonable price, and then say whether it be fruit or vegetables that are most out of the reach of people who can do without fruit to some extent, but who would consume vegetables in quantity if they could only procure them. From these and other causes it is a fact that a vast portion of the inhabitants of all our great towns and plenty of our small ones are absolutely without wholesome green food of any kind from one year's end to the other.

But the question is, Could vegetables be grown to come within the reach of the masses, and, at the same time, to pay the growers? No doubt they could, provided greater facilities were afforded in the way of markets, where people could go at convenient hours, and without travelling a mile or two, to buy what they wanted. It is not to be expected, of course, that it would pay farmers generally to turn their farms into market gardens, but it would pay some of them near large towns to do so, and simply devote their land to the culture of common vegetables. Fruit crops are not to be depended upon with any degree of regularity, but there are few or no parts of the country where good crops of common vegetables could not be secured any season with certainty, and there is as little doubt that they could be equally readily disposed of at remunerative prices.

Before, however, the question of growing and disposing of either fruit or vegetables on an extensive scale and for the benefit of the people can be settled, the question of market accommodation must be considered. In some large towns there are what are called fruit markets, but they are monopolised for other purposes. In Sheffield, for example, the dead meat and poultry market is a good one of its kind, and is devoted to the purpose for which it was built; but what is called the fruit market, a large, commodious, and well-lighted structure, every way adapted to the display of garden produce on small stalls, like the Halles Centrales in Paris, is almost exclusively devoted to the sale of everything except vegetables and

fruit, for which I have always understood it was originally intended.

Would the working classes add vegetables to their dietary if they could procure them good and cheap, is a question sometimes asked, and one which may be answered affirmatively at once. As things are at present they can only procure vegetables as a luxury, occasionally, perhaps, on a pay night, and travellers in local trains on Saturdays will often see the wives of working men returning from market with a few green vegetables in a basket along with their groceries and other goods, and which represent the week's supply. During prosperous years we have been told by the dealers that the poorer classes are amongst their best customers. The mere fact that the refuse of the greengrocers' stalls is often sold to hucksters, who sell it among the poorer and lower orders of the towns, is sufficient evidence of the desire to obtain green food when it can be had at a reasonable price. J. S.

REGENT AND DALMAHOY POTATOES.

"J. S. W.'s" communication (p. 247) in reference to these Potatoes confirms what I wrote on the subject, that under the name of Regent several sorts are grown, some earlier, others later; but the original Regent I maintain, despite what may be described in catalogues or elsewhere, is not either late in coming to maturity or can be correctly classed as a late Potato in any way. If the seed be fairly prepared and planted at the proper time, the tops, in most parts of the country, will be dead or dying by the end of August; it shows its intermediate season habit by sprouting earlier in the spring than the late-growing, late-keeping sorts, and also by its deterioration in eatable qualities sooner than the late ones. I write from memory, but I believe it is over twenty years since I became acquainted with the Dalmahoy, which then made its first appearance in the Potato-growing districts of Cheshire, where I was living at the time, and where it was soon generally known and largely grown, both as a field and garden crop. It was a rougher and deeper-eyed Potato than the Regent, as well as later in every way. The sort now sold by many as Dalmahoy is very different from the kind first known under that name, and I have often heard others make the same remark in reference to the forms exhibited of this as well as of the Regent and many others, and this notwithstanding the difference that soil and cultivation have upon them. We often hear late Regents and early ones spoken of, and immense quantities of a late deep-eyed but very good Potato are cultivated in Lincolnshire and other Potato-growing districts, but all the argument possible will never make such into the true Regent. In the case of any vegetable of which there are such numbers of varieties in cultivation as there now are of Potatoes, with their liability to get wrongly named, there is sure to be much confusion. The sort now known as Forty-fold is a totally different kind from the original, and I could point to numbers of similar instances. T. BAINES.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The Chiswick Trials of Vegetables.—I have no doubt that "A. D." is as familiar as most people with the different varieties of the Potato, judging from what he has written on the subject from time to time, and if he be determined to pin his faith on the Chiswick trials in all cases, no one need interfere, but there are numbers who do not, and the decision of the Chiswick authorities that a well known early Potato and an equally well known late one are identical, gives some colour to the belief that they are not infallible. Both them and "A. D." have simply been deceived beyond all manner of doubt. The Potato in question was sent out by its raiser as an early kind, and was subsequently proved to be an early one by those who grew it for twenty years afterwards or longer. How it turned out to be a York Regent at Chiswick, is for the Chiswick authorities to explain.—J. S. W.

Scarcity of Vegetables.—I had 120 plants of Snow's Winter White Broccoli planted on a sheltered spot on a south border, and out of that number all were killed except ten. The frost has also killed Cabbage stamps and Scotch Kale. Brussels Sprouts have stood best with us, and the more leaves they have on them the better they stand the frost, as the leaves protect the Sprouts. In autumn we had a quantity of Lettuce and Endive. The first sown early in July we took up and put in pits and cold Peach houses, thinning them as they were wanted. Of Endive we had a good plantation in the open border, which we protected with dry Fern. From this we lifted plants as we wanted them and put them in the Mushroom house to

blanch; this carried us on some time, and by having a good stock of Chicory, Mustard and Cress, and Celery, I shall be able to keep up a daily supply till the end of March, when I shall have to depend on Lettuces and Chicory, Mustard and Cress, and Celery till Radishes come in. Onions in a green state are by some much prized. Of those sown to stand through the winter in the open air not one in fifty is left, but I have plenty in pits sown in January, and by pricking them off into boxes I shall have enough. I only grow two sorts of Lettuces, and one kind of Endive for winter use. A winter like the past proves the advantage of having plenty of pits and frames in which to keep winter vegetables.—J. C. L.

Dwarf Peas for Small Gardens.—Inquiries as to what are the best sorts of Peas for small gardens, kinds that want no sticks, as so often addressed to me that I have no doubt there are others beside my correspondents to whom the information would be welcome. Maclean's Advancer is the best early dwarf Marrow, but, as an earlier dwarf semi-Marrow, First Crop may be sown to precede it. For a middle crop use Maclean's Wonderful, and for the latest Laxton's Omega. These are the dwarfest of their class. Another good selection, rather taller, but still classed as Dwarf Peas, are Prince's Royal, Premier, and Veitch's Perfection. All of these produce Peas of the very best quality.—A. D.

THE LIBRARY.

VAN HOUTTE'S FLORE DES SERRES ET JARDINS DE L'EUROPE.

THE fourth and concluding triple part of the twenty-second volume of this profusely and most beautifully illustrated, but, alas, most irregularly-published work has just reached us, and it, perhaps, hardly in any material degree superior it is, at least, fairly equal in interest and beauty to recent issues of the work, which, for the future, it is to be hoped will appear with greater regularity. This triple number contains, as usual, twenty-seven coloured plates or their equivalents, comprising portraits of the following plants:—A double plate representing the pitchers of three fine varieties of *Nepenthes*, named respectively *N. alba-marginata*, *N. Rafflesiana*, and *N. sanguinea*. A double plate representing six varieties of the fine double *Cinerarias* raised and sent out by Messrs. Haage & Schmidt, the well-known Erfurt house, which, from their perfect duplicature, more resemble miniature Dahlias or forms of the double *Groundsel* than *Cinerarias*; indeed, they were absolutely mistaken for double *Groundsel* when first sent to this country as cut blooms only to a leading London florist; but, unfortunately, they generally deteriorate when propagated by cuttings, which much detracts from their value, as they have constantly to be reproduced from seed, of which only a small proportion, of course, comes double. A double plate of *Amarantus atro-purpureus*, a fine, deep blood-red, tasselled form, said to be a native of Calcutta and to be well adapted for summer bedding if sown in the open air in May. A double plate of *Azalea indica* Souvenir du Louis Van Houtte, a most beautiful, semi-double, self variety of clear bright rose colour, with individual flowers of immense size and fine substance. A double plate of *Camellia Roi des Belges*, a fine rose-coloured variety, the blooms of which are sometimes flaked with white. A double plate of *Garcinia Mangostana*, the tropical fruit known as Mangosteen, a native of the Molucca Isles, and showing blossom as well as interior and exterior of the fruit. A double plate of Hybrid Rhododendron Comte Charles de Kerchove, raised at Ghent, with large, whitish blossoms, distinctly edged with pale pink and with distinct chocolate-coloured markings on the upper petals. A double plate of the beautiful fine foliaged plant, named Maranta Massangana, a native of Brazil. A double plate of the Grape Ingram's Prolific Muscat, which we consider altogether out of place in a work of this nature. And also single plates of:—Seven varieties of *Cyclamen* (named respectively—1, *Atkinsii*; 2, *persicum amarantium*; 3, *album punctatum*; 4, *persicum roseum*; 5, *Cornu*; 6, *Aleppicum candidissimum*; and 7, *persicum album*), all of them very pretty little flowers; *Masdevallia Poristeria*, a terrestrial Orchid, more curious than ornamental, with brown and greenish flowers; *Fremontia californica*, reproduced from the "Botanical Magazine"; *Cryptopodium punctatum*, likewise a reprint from the same work; *Allium oreophilum*, a pretty little rose-coloured Garlic, a native of the Caucasus, already figured in Rogel's "Gartenflora"; *Blumenbachia Chiquitensis*, a reprint from the "Botanical Magazine"; *Pityrospasma acerinum*, a pretty, white-bloomed, hardy herbaceous plant from Japan—also known under the name of *Actaea japonica*, and with rather handsome foliage; the inflorescence of the almost hardy Chinese Palm (*Chamserops Fortunei*), now frequently met with in our gardens; the fine specimen of *Araucaria imbricata* taken from

the frontispiece of Mr. A. Mongredien's work on "Trees and Shrubs in English Plantations," and which is a rather fanciful portrait of the Dropmore tree as it appeared some three or four years ago; this plate we consider but a makeshift, and altogether unworthy of insertion in such a work as that now under notice. W. E. G.

EFFECTS OF THE WINTER IN SOUTH DEVON.

THE various Citrus trees, for which this place has been famous for more than two centuries, though slightly damaged, are safe, with the exception of a fine Bergamot Lemon, which is in a doubtful condition. The same may be said of a Sweet Lime. These trees are on south and east walls, only protected by frames of wood or reed. *Dracenas* in a dry situation are unharmed, while smaller plants in a damper site are quite dead. Hardy *Falms* are wholly uninjured, as are also *Camellias*, which are laden with flower buds. Hybrid *Rhododendrons* are quite safe, especially some very fine white varieties from the Sikkim Aucklandi. One fine specimen of the true *R. arboreum*, several feet high, is unharmed, as is likewise the Ceylon *R. nobile*. A few of the Sikkim *Rhododendrons* have their foliage damaged. Large plants of *Myrtus apiculata* against a wall will lose a good deal of their foliage. The *Loquat* is uninjured, as are also *Berberis Fortunei*, *nepalensis*, and *Hookeri*, three species of *Escallonia*, and an American *Aloe*. A huge mass of New Zealand Flax, hitherto uninjured, is much damaged. A vast number of young and rare shrubs, planted in a new piece of the American garden, are killed, as might be expected after such an arctic winter. Shrubby *Veronicas* are much injured, if not quite dead, with the exception of *V. Traversii* and *V. pinguifolia*. *Clematis indivisa* is much damaged. Three *Embothriums* are unharmed, but one, the largest, a magnificent specimen approaching 30 ft. in height, in a low and damp situation, is damaged and will lose all its leaves. *Magnolia Campbelli*, growing near it, is also damaged. Five species of *Eucalyptus*, one, *E. amygdalifolia*, between 20 ft. and 30 ft. high, are quite dead, but seedlings of *E. coccifera*, though slightly injured, are alive, as is also a huge umbrageous tree, with a trunk 5 ft. or 6 ft. in circumference, incorrectly named *E. montana*, from the highlands of Tasmania. A beautiful specimen of *Cantua dependens* is quite dead, and a tall *Acacia* dead, both are much injured, but may recover. *Fortunia sinensis* is dead, and *Lavrus aromatica* is killed to the ground. Seedling *Bambusa arundinacea* are injured, but many Chinese species have done well. The Japanese *B. Metake* is wholly uninjured, and forms huge verdant masses. The following are quite safe, viz., *Olea ilicifolia*, *Ilex latifolia*, *Acacia Nenu*, *Morus hispanica*, *Oreodaphne californica*, *Choisya teretica*, *Desfontainia spinosa*, *Drynys Winteri*, *Pyrus Maulei*, and *Bigworbis chrysantha*. JOHN LUSCOMBE.

Combe Royal, Kingsbridge.

EFFECTS OF THE WINTER IN NORTH DURHAM.

AT last the snow is gone, and we may now somewhat safely predict that we are clear of the tyranny of the storm king, who has maintained his supremacy since the middle of November. The extraordinary weight of snow that fell at various times has been very destructive to the finer kinds of shrubs and specimen Conifers. As I mentioned in a former note, I had seen several *Beeches* broken at Lumley Castle; since then I have witnessed great destruction in the same direction. Splendid old *Cedars* of Lebanon have had their limbs split off by the bole, and some huge evergreen Oaks have not fared much better; in fact, all the larger trees have carried their heavy burden till at length it has disfigured them for ever. In spite of this heavy covering of snow, the frost, which was as remarkable for its severity as the snow was for its weight, has severely injured many of our finest shrubs. Every day sees the ground strewn with leaves of large green Hollies, while, singularly enough, the variegated sorts are apparently little hurt, and the *Laurestinus* has not suffered in the way one would have expected. A handsome *Araucaria imbricata*, something like 20 ft. high, has not a brown spine nor a broken branch on it. A large *Hydrangea*, which has been planted not many years, is showing signs of starting into growth, evidently not much the worse for the ordeal through which it has passed. Some of the *Rhododendrons*, of which we have a splendid collection, have had their flower buds killed, but there are still plenty left to make a good display. Roses have suffered as much, if not more, than anything else, the mischief showing itself in the form of a narrow brown collar, sometimes nearly at the bottom of the shoot, necessitating its entire removal. In an unheated house, where some zonal *Pelargoniums* had been left, they are completely killed, while, in the same house, *Selaginella denticulata* is growing as luxuriantly as if in a Fernery.

Passing to the kitchen garden matters are even worse; almost all the autumn planted Cabbages have perished. Some Broccoli may make small heads, but the greater portion of it has failed, and so have autumn sown Onions, while Globe Artichokes will scarcely recover. Owing to the early advent of winter, and the uninterrupted stretch of continued bad weather, kitchen garden work is a long way behind, and now when the severe weather is gone, bringing up work in arrears, and the usual extra push that needs to be made at this season, will occupy all hands. Land that has been dug during winter is now in capital working order, but that which has lain undug will be in a bad state, particularly in the case of strong soils; still it will, perhaps, be the best plan to dig and crop it as we go on, as the land will not be much benefited by the short exposure it must necessarily have before being wanted.

To predict the success or otherwise of our fruit crops may yet be premature, but to all appearance we shall have good crops. Peaches, Nectarines, Plums, Apricots, Pears, and Morello Cherries on walls, are thickly set with plump, healthy bloom buds. Standard and pyramid Apples and Pears have a fine healthy appearance. Small fruits also look well, and what is very odd, the birds have not taken to the buds this year as usual. With immunity from frost, we may thus fairly calculate upon having a good fruit year, but should late frosts occur, or easterly winds prevail when the trees are in bloom, we here, at least, within seven or eight miles of the German Ocean, may count upon the destruction of our crops. TYNEDALE.

THE INDOOR GARDEN.

CELOSIAS AND THEIR CULTURE.

THERE are many fine flowering annuals for both out and indoor decoration, but I know of none more ornamental or useful than the Celosias. They may be had in flower from June to autumn, and during all that time they may be used for room or conservatory embellishment with excellent effect. They have no scent worth mentioning, but the colours of the flowers are both interesting and varied. As with other annuals there are many strains of Celosias; some exhibit a good deal of the cockscomb style, others form long narrow inflorescence, but the best produce plumes more leathery than the finest heads of Pampas grass. It may be said these are the only kinds really worth growing, so very much superior are they to all others, but the worst of it is they are rather difficult to secure. The best way is to buy a mixed packet of seed, grow the whole well, and save seed only from the very best; we thus improve the strain, especially if seed be saved in this manner year after year. Celosias produce seed freely, but, as is often the case, the best are always the shiest in this respect. When the flowers show signs of decaying, the plants should be placed in some warm, dry, airy house, to prevent them from damping and to ripen the seed. This should be gathered a little before it is fully ripe or it may drop out. The best, or, in fact, the only mode of propagating the Celosia is from the seed. It may be sown from February to July, firstly to produce early plants for midsummer and autumn blooming, and lastly for plants to bloom late in autumn and midwinter. The seed may be sown either in pots or pans; we generally use 8-in. pots for the purpose. They are filled quarter full of crocks, over which is put some rough material, and the remainder is made up of a mixture of loam, leaf-soil, and sand in equal parts. This compost is made moderately firm, the seed is sprinkled thinly on the surface, and then covered over with a little of the same mixture; a gentle watering is then given, and the seed soon germinates in either an air heat of 60°, or a bottom heat of 70°. Under the latter treatment the young plants come up sooner, but healthy young seedlings may be secured both ways. As soon as the young plants are about 2 in. high they are carefully lifted and potted singly in 3 in. pots, using the same kind of mixture as that in which the seed was sown, and giving them the same temperature, &c., as before. From this time onwards there is only one pest that is to be guarded against, and that is the red spider; it is particularly fond of the Celosia, and very often spoils the plants when not checked. When young the leaves may be sponged if there be any sign of spider, and as the plants become large, frequent syringing will keep it in subjection.

As the young plants gain size it will be found that the pots soon become filled with roots, when a shift into larger pots

must be given, the size being determined by the amount of roots; previous to flowering, care must be taken that they never get pot-bound, for when that occurs they invariably start into bloom, thus affording a certain means of flowering them at any time and in any sized pot. From 3-in. pots they should be shifted into 5-in. or 6-in. ones. Fair-sized plants may be bloomed in the latter size, and when they are wanted for small vase decoration this size will be found very useful. After being taken from the 3-in. pots well-decayed cow manure should be substituted in the potting compost for the leaf soil, as Celosias are rather strong-feeding plants. When they have been potted a second time they may be again placed in a mild, close atmosphere, but after the beginning of June they succeed very well in an unheated frame, where, being near the glass, dwarf, sturdy plants are the result. They may be placed in the conservatory just as the flowers are forming, but they should not be taken into a room until they have nearly or quite expanded, and the time during which they remain in bloom will surprise people not acquainted with them. Three months is not an unusual time for them to retain all their good properties in this respect; owing to this, plants which come into bloom in July will be found in the same condition in the beginning of October, and plants just coming into bloom in October will remain so until after the new year. The latter stock of plants should be kept hardy, that is, not grown in a close, warm place, but in frames fully exposed to the sun. The younger and more vigorous the plants are during the short days the better do they bloom and withstand a low temperature. When in flower, especially in winter, they do not require much heat; a temperature anywhere between 35° and 60° suits them. What they want more than heat is a dry atmosphere, as damp soon rots the feathers. It is chiefly on this account that they succeed so well in rooms. I have also found them to last a very long time in church decoration, a point of importance in the case of those who (like ourselves) have to decorate the church nine months out of twelve. If any one imagines that Celosia culture is a difficult matter, let me assure them to the contrary; no plants are more easily grown, and none will yield a better return for attention paid to them, whether that be much or little. CAMBRIAN.

Forced Shrubs.—It may be well to tell the inexperienced that when hardy shrubs that have been forced are taken out of conservatories, &c., they should not be placed out-of-doors under shrubs, or in any out-of-the-way place; on the contrary, they should be put into some place to make their growth before being put out. Thus treated, they will force much more easily the next season. Some Rhododendrons thus managed for four years have done good service, and the same may be said of Ghent Azaleas.—J. CROOK.

Camellias, &c., at Kingston.—There are few, if any, cultivated plants that exhibit such a difference in the length of time during which they will keep on flowering when planted out as compared with being grown in pots or tubs as Camellias do. We lately saw (second week in March), in Messrs. Jackson's nursery at Kingston, a number of tall plants occupying a lean-to house facing the north, bearing a considerable quantity of flowers, although they had been in blossom ever since September last, and from that time until now had produced a continuous supply of finely-developed blooms for cutting. Amongst them was the fine old red kind called *eximia*, the beautiful pink-flowered *Fordi*, and the straw-coloured semi-double *ochroleuca*, a great favourite with those who object to formal shape in flowers. This establishment has been long noted for its fine collection of hard-wooded plants, and at no time have we seen them look better than they now do, especially the specimen hard-wooded *Heaths*. Amongst these we noticed grand examples of *Cavendishii*, *Fairreana*, *Candolleana*, *tricolor impressa*, *tricolor speciosa*, *Aitonii*, *Turnbullii*, *semula*, and an unusually beautiful plant of *depressa*, literally studded with flowers just beginning to open. Of less well-known varieties the collection contained *Lindleyana*, one of the very finest high-coloured sorts in cultivation, and *mundula*, a distinct kind, the flowers of which are star-shaped, opening flat like those of *E. delecta*. Amongst greenhouse plants we remarked the true variety of *Aphelaxis rosea*, 3½ ft. through, and examples of the dark-coloured *A. macrantha purpurea*; *Boronia serrulata*, was thickly set with flower-buds; numerous large plants of *Phenocomas*, *Pimeleas*, *Hedromas*, *Staticeas*, and some handsome *Azaleas*, retaining plenty of healthy foliage, which augurs well for their flowering satisfactorily. We likewise saw a number of *Vandas* in more than ordinary

strong condition, *Dendrobium Parishii*, and *D. Bensoniae*, little over a twelvemonth imported, have pseudo bulbs from 15 in. to 18 in. long; *Dendrobium barbatulum* has been in bloom five or six weeks; *Caelogyne cristata* is coming on with a number of flower-spikes, which appear as if they would not open before the middle of April, showing the length of time it may be had in flower, with a sufficient quantity of plants at command.—P. G.

LACHENALIA PENDULA AS A BASKET PLANT.

This is grown to perfection in baskets in Messrs. Veitch's nursery at Chelsea. The baskets, which are made of wire, are round, lined with Moss, and filled with good soil. The bulbs are planted at equal distances apart in the Moss all over the baskets, and when in flower they form large balls of brilliant blossoms and deep green leaves. The bulbs are taken out yearly; the baskets are refilled with fresh soil and planted again. Abundance of water is necessary after the plants commence to grow, and this can best be supplied by immersing the baskets wholly in a tank. Grown in the manner just described *Lachenalias* thrive amazingly, and are seen to better

Basket of *Lachenalia pendula*.

advantage than when grown in any other way, whilst for hanging either in windows, porches, or conservatories, they are both useful and attractive. S.

GARDENING FOR THE WEEK.

Flower Garden.

Ivy cut or clipped before new growth commences will present a very different aspect throughout the season from what it will do if deferred till new growth has commenced; therefore, let it be cut at once. Hedges, screens, lines, or belts of shrubs that have to be kept clipped in a formal manner should now be operated on. Many common Laurels, Bays, and Laurustinus have been terribly injured by the severe weather, hence the pruning of these had better be deferred for a few weeks longer, till it can be seen as to whether or not they should be cut right down and allowed to break from the bottom. Any that now seem dead had better be headed back at once. Climbing Roses, Clematises, Virginian Creepers, Wistarias, and other climbers will now require attention as to pruning, regulating, and nailing, and any that need additional stimulus to ward off parasites and promote more vigorous growth should be top dressed and mulched. Herbaceous plants may now be divided, regulated, and rearranged; many kinds that are just starting into growth, such as *Pyrethrums*, *Potentillas*, *Asters*, *Phloxes*, and *Delphiniums*, will bear division without the least apparent check, and retain their vigour longer than when left in the same position for years. When replanting, take pains to arrange the plants, both as to height of growth and colour of flowers, in order that the tall growers do not overshadow the dwarfier kinds, or, that there shall be several plants in juxtaposition of the same colour. When the arrangements are finished, any vacant spaces there may be will come in for the sowing, or planting out, of *Sweet Peas*, *Lupins*, *Mignonette*, *Stocks*, *Asters*,

Zinnias, and other annuals, fall of which add both to the beauty and interest of such borders. Hints as to other outside operations were given at pp. 184 and 223. The preparation of bedding plants, both from seeds and cuttings, is now the most important indoor operation. If the sub-tropical plants were sown, as recommended, a few weeks ago, they will now be ready to prick out or pot on, as the case may be. After that, till new growth has started, keep them close and shaded, and then grow them in as cool a temperature as is compatible with health and sturdy growth. Seedlings of *Amarantus*, *Perillae*, *Cineraria maritima*, and others of a similar nature, may be pricked off into boxes, and grown in an intermediate temperature. A better plan is to prick them out in heated pits, and as soon as they have become established turn off the heat, and gradually expose them to the atmosphere. *Calceolarias*, *Verbenas*, *Gnaphaliums*, and *Lobelias* may be planted out in turf pits, and covered with straw hurdles, mats, or frigid domo. As we have not the convenience for turf pits, we plant them out in trenches that have been prepared for *Celery*, and cover with evergreen boughs. Many *Pelargoniums*, for want of room, are treated in the same way, and hitherto the plan has been successful. For vases and basket beds, the Ivy-leaved *Pelargoniums*—many varieties—are invaluable, and cuttings put in now will make good plants by bedding out time. Amongst other appropriate creepers for such purposes may be named *Cobaea scandens*, *Maurandya Barclayana*, *Convolvulus major*, and *Tropaeolum canariense*, all of which are best raised from seeds.—W. W.

Indoor Fruit Department.

Pines.—The earliest Queens will now be swelling fast, and may with advantage have an increased temperature by day and also more air moisture; close up early, say about two o'clock, syringing the walls and floors when closing and the plants occasionally, especially when the air is parching and the sun powerful. Frequently examine the plants to see if they want water, as they should now incline to the wet rather than the dry side of a medium state of moisture, a condition which is most desirable for plants swelling off their fruit. Remove all gills as they appear, and all suckers, except what are absolutely required to keep the desired stock. The bottom heat should be maintained at 85°, and the top heat according to the weather, that is, if cold north-easterly winds prevail 65° will be sufficient, but at other times not less than 75° should be the rule, and air should be given when the thermometer reaches that point; it should be reduced as heat declines, finally closing with a temperature of 90° or 95°. The last potted suckers will by this time have formed roots, and therefore may be treated as established plants; give more air, and dew them overhead about twice weekly, and if there be no evaporating pans on the pipes syringe the walls and floors, after the manner indicated for the fruiting plants. When the sun is powerful slightly shade for a couple of hours at midday till the plants have become accustomed to the change from clouds to sunshine.

Strawberries.—If we could but annihilate that most persistent enemy—red spider, what a boon it would be to cultivators. Our first lot of plants before the fruit was gathered were badly infested with it, and instead of reserving the plants for open-air planting we have had them destroyed, and recommend others who may be in the same fix to do likewise. Successional batches are not likely to get affected, as the days being longer and brighter less fire heat is needed, and the syringing can be more freely plied. Keep the atmosphere on the side of dryness when the plants are in flower, or the fruit is near maturity, but at all other times have plenty of moisture. When it is necessary to retard ripe fruit, it is easily done by allowing the plants to become moderately dry, and then moving them to a cool fruit room; in such a position we have had them keep in perfect condition for a week, and frequently longer. Precaution must be taken against injury from mice or rats, which may have gained access in the room.

Extracts from my Diary, March 29 to April 5.

FLOWERS.—Boxing and potting *Pelargoniums*. Propagating *Verbenas*, *Mesembryanthemums*, *Lobelias*, and *Ageratums*. Planting out *Gladioli*. Re-arranging houses and sowing seeds of *Poinsettias*. **FRUIT.**—Shifting *Strawberries*, the fruits of which are swelling, into a warmer house, and moving those which are ripening fruit into a cool Vinery, in order to improve their flavour. Tying and stopping the shoots of *Cucumbers*, and putting fresh lining to Pine pit. Top-dressing *Strawberry* beds, and making hotbed in Pine pit on which to plant *Melons*. Tying in shoots of *Peach* trees in second house. **VEGETABLES.**—Sowing *Major Clarke's Celery* in boxes in frames. Preparing old *Rhubarb* ground for *Potatoes*. Sowing *Veitch's Self-protecting Broccoli* and *Autumn Giant Cauliflower* in frames. Planting *Myatt's Prolific Tomato*, and preparing sets for the main field crop. Pricking out *Potatoes* from seed pans into boxes for planting out-of-doors in June.

PLATE CLXXIII.

THE CALCEOLARIAS.

(WITH A COLOURED PLATE OF *C. FUCHSIÆFOLIA*, A NEW SPECIES.)

Drawn by CONSTANCE PIERREPONT.

FASHION seems as potent in the garden as in the boudoir, and, in the restless hankering after something new, many an old favourite is neglected for, or supplanted by, something less deserving of our attention. This is inevitable, and perhaps not so much to be deplored, for we cannot always be admiring the same flowers, any more than we can derive enjoyment from hearing the constant repetition of one tune, be it ever so sweet; and, after all, as old fashions in dress are revived, so will plants that were formerly in favour come into vogue again. It is true, to a certain extent, that bedding Calceolarias were in fashion until they were, or appeared to be, worn out, and many a gardener would rejoice could he depend upon them as heretofore. It is a singular fact, that they still thrive unaided in some places, whilst in others all the skill that can be brought to bear on their treatment is unavailing and fruitless. But the original wild forms have almost entirely disappeared from British gardens, many of them doubtless because they could not hold their own in competition with more attractive introductions. The genus *Calceolaria* is, however, so rich in species, and presents such a wealth of variety in form and colour that it deserves a few columns by way of a re-introduction to the lovers of flowers. It comprises upwards of 100 distinct species, including annual and perennial herbs and dwarf shrubs. Its geographical area almost exactly coincides with that of the genus *Fuchsia*, ranging, as it does, from Mexico to the southernmost point of South America, and re-appearing in New Zealand; but, unlike the *Fuchsia*, it is not represented on the eastern side of South America, at least only in the extreme south. The greater number of the species inhabit mountain valleys, ascending to an elevation of 13,000 ft. to 14,000 ft. within the Tropics, where they enjoy a moist equable climate, which is never very hot and never very cold. Some few occur in the arid districts of Chili; they find their greatest concentration in Chili, Peru, and Ecuador; only about four species are known to grow in Central America and Mexico, and two have been discovered in New Zealand. In foliage they offer as great a variety as the most polymorphous genus, for, in addition to those described below, there are such species as *pinifolia*, *ericoides*, *hypericina*, &c., names sufficiently indicative of their peculiarities without further explanation. Of their duration mention has already been made. With regard to the flowers, the species included in the following selection illustrate their whole range of variation. The peculiarities of the flowers of each species being given in the descriptions, it will suffice here to explain their general character. The corolla belongs to the bi-labiate or two-lipped type, but in most species, and especially in the hybrid races met with in gardens, one of the lips is reduced to very small proportions, whilst the other is enormously developed in the form of a pouch. On the other hand, *C. violacea* and others have an almost regularly two-lipped corolla, the lips being concave instead of pouched. In all the species known, save one, the flowers contain only two stamens each, but in this (*C. triandra*) there are three fully-developed stamens. Not nearly all of the species in this selection are deserving of cultivation in the same collection from an ornamental point of view, but their respective merits depend greatly upon the taste of the cultivator. Independently of the hybrid races, herbaceous and shrubby, the history and parentage of which are given in some detail under the species concerned, these here enumerated are some of the most ornamental:—*C. hyssopifolia*, *Henrici fuchsiæfolia*, and *violacea* (shrubs); *C. integerrima*, *alba*, *amplexicaulis*, *thyrsoidea*, and *flexuosa* (half shrubs); *C. piscoensis*, Darwini, Fothergillii, Pavoni, *arachnoidea*, *corymbosa*, *plantaginea*, and *tenella* (perennial herbs); and *C. chelidonioides* (an annual herb). It is difficult to classify the species according to their nature and duration, as some of them are herbaceous or half shrubby, according to the climatal conditions, but some approach to this has been attempted. Although a few of the species are sufficiently hardy to with-

stand the ordinary winters of the south-west, it should be borne in mind that Calceolarias are essentially greenhouse plants, and several of them are of special value as winter-flowering plants. Mr. T. Smith (Rodger, McClelland & Co., Newry) kindly forwarded some practical notes, which are embodied under the respective species almost in his own words.

Shrubby species.

1. *C. fuchsiæfolia*, *—Though closely allied to *C. cerasifolia*, *C. padifolia*, and specimens named *C. deflexa*, in Kew Herbarium, it does not exactly agree with any of these. Possibly a revision of the genus with more ample materials may lead to its identification with a described species, but in the meantime it may bear the name here proposed for it. Our plant differs from its nearest allies in being almost entirely destitute of hairs and any glutinous exudation, and more especially in the shape of the corolla. The absence of hairy appendages and glutinous matter may be due to the different conditions to which the plant is subjected under cultivation, and with regard to the shape of the corolla, this is a character not easily determined from dried specimens, though dried specimens of a plant sent to Kew many years ago by Messrs. Veitch are easily recognisable as the same species. When out of flower it exhibits a marked resemblance in habit and foliage to some of the hybrid *Fuchsias*, which have the under side of the leaves of a pale or silvery hue. It is an erect shrub, 2 ft. to 3 ft., or perhaps sometimes more, in height, with glossy foliage. As the accompanying plate does not show the peculiarities of the shape of the corolla, it may be briefly described. The lips are nearly equal in diameter, the lower one, however, being saccate and very much inflated, has the appearance of being much larger than the upper, which is almost flat and circular, and intruded around the base of the ovary, the intruded part being furnished inside with a ring of white glutinous hairs. None of its immediate allies appear to be, or have been, in cultivation. There is, however, a cultivated specimen of *C. tetragona* in Kew Herbarium, a species of the same section, with stout, distinctly quadrangular stems, broader, thicker, glutinous leaves, and a larger greenish-yellow calyx. Several of the species of this section named, all of which are Peruvian, are highly ornamental. Of this particular one Mr. T. Smith says, "it requires to be grown freely during the summer months in a cool, shady situation, as its glossy leaves are most impatient of summer sunshine. It should be housed before danger from frost arrives, and it will then come into bloom about October and continue a beautiful mass of golden flowers throughout the winter months. Unquestionably it is the handsomest yellow-blossomed, winter-flowering plant in cultivation." The accompanying plate was drawn from a living plant supplied by Messrs. Rodger, McClelland & Co., nurserymen, Newry, County Down, Ireland. Most likely a native of Peru, where it and all its nearest allies are at home.

2. *C. hyssopifolia*.—A shrub of narrow erect habit, having rather slender stems well furnished with narrow leaves, 1 in. to 2 in. long, more or less glutinous, and clothed with a white fur on the under surface. Flowers of a clear pale yellow, in shape resembling those of the well-formed herbaceous hybrid class, but with slight indications of lobing around the circumference, and scarcely an inch in diameter. Certainly a very attractive species. It is a native of the Quitian Andes, at an elevation of 9,000 ft. to 13,000 ft., and was introduced into this country by Prof. Jameson, of Quito, who sent it to Mr. I. Anderson-Henry, of Edinburgh, in whose garden it flowered in 1865; and it was figured in the "Botanical Magazine," t. 5548. *C. Hartwegii*, *lavandulæfolia*, *rosmarinifolia*, and *gossypina* are allied ornamental species, especially the last, not yet introduced.

3. *C. Henrici*.—A handsome shrubby species of comparatively recent introduction, figured in the "Botanical Magazine," t. 5772. It was sent by Professor Jameson, of Quito, to Mr. Isaac Anderson-Henry, of Edinburgh, after whom it was named by Dr. Hooker. Its affinities are with *C. hyssopifolia*, from which it differs in its longer (4 in. to 5 in. in cultivated specimens), broader leaves, and somewhat smaller, more nearly globular flowers, without any indications of lobing around the circumference of the lower lip. The flowers, too, are of a rather deeper yellow. A native of the Andes of Cuenca.

* *CALCEOLARIA FUCHSIÆFOLIA*, species nova.—Fruticosa glabra glutinosa, 2-3 pedalis; ramis terribus gracilibus; foliis oppositis petiolatis, Fuschie crassidam, ovato-lanceolatis, 2-3 pollicaribus callosae-areolatis acutiusculis, discoloribus, supra viridibus reticulato venosis, subtus argenteis, petiolo supra candelulato leviter barbato, semipollicari; floribus flavis cymoso-corymbose graciliter pedicellatis; calycis laciniis rotundato-ovatis, acutis reflexis, nunquam leviter glutinosis; corollae labiis subaequalibus, inferiore elliptico saccato-calceiformi, ultra medium aperto, superiore latiore rotundato, valde compresso, basi circa ovarium intruso intus annulo villoso-glanduloso prædito; staminibus declinatis, filamentis brevibus, antheris magnis; ovario glabro, stylo filiformi. Affinis *C. cerasifoliae* et *deflexae*, sed differt, foliis discoloribus glutinosis atque etiam forma corollae, &c.—W. B. HENKEL.

4. *C. violacea*.—This belongs to a small section of the genus, formerly regarded as generically distinct, under the name *Jovellana*, on account of the lips of the flower being nearly equal and concave instead of pouched, forming together a gaping, mouth-like corolla; and on account of the anther cells being contiguous or confluent; but connecting links of every grade have since been found. *C. violacea* is a spreading, much-branched shrub, 3 ft. to 4 ft. high in cultivation, with deeply lobed leaves, 1 in. or less in length, and lilac blue flowers spotted with yellow and red inside, and from $\frac{1}{2}$ in. to 1 in. long. It was introduced many years ago from South Chili, and figured in the Bot. Mag., t. 4,929. One collector (Bridges) states, on a label in Kew Herbarium, that it delights in decomposed granite. Mr. Smith informs me that it is the only species of *Calceolaria* hardy at Newry, and this season it has been out to the ground by the frost, but shortly after the frost broke it begun to show signs of growth. In ordinary seasons it blooms freely in April and May on shoots of the preceding season's growth. *C. triandra* has the habit of *C. violacea* and small, pinnately lobed leaves, but it is remarkable in the genus for having three stamens, instead of only two.

Half-Shrubs or Under-Shrubs.

5. *C. punctata*.—A half-shrubby species, with flowers similar in shape to those of *C. violacea*, but rather larger, and almost exactly the habit, foliage, and inflorescence of our native Figworts (*Scrophularia*). The leaves are 3 in. to 5 in. long, oval, and doubly toothed; the flowers, according to Dr. O. Cunningham, naturalist to the surveying expedition of H.M.S. *Nassau*, are white spotted with lilac, and the whole plant has a most unpleasant odour. Mr. R. Pearce introduced it in 1862 for Messrs. Veitch, and it is figured in the "Botanical Magazine," t. 5392. Although the flowers are so like those of *C. violacea*, the resemblance ceases there. The variety figured in the "Botanical Magazine" has lilac flowers with a yellow blotch on the inside of the lower lip. A very common Chilean plant.

6. *C. polifolia*, Hooker, Bot. Mag., t. 2897.—An erect branching undershrub, with small ovate or oblong leaves, clothed with a white felt-like down. The flowers are few, and about a third of an inch in diameter, subglobose; the upper lip yellowish white, about half the size of the other, and turned down upon it; lower lip of a more decided yellow. Introduced from Chili by Mr. Cruckshanks, in 1826. There are about half-a-dozen others of this section, not any of them remarkable for their beauty.

7. *C. flexuosa*.—A very fine subshrubby species, with cordate coarsely toothed leaves, 3 in. to 4 in. long, and large terminal panicles of golden yellow, hairy, nearly globular flowers about 1 in. in diameter. Stems rather slender and weak, leaves thin, calyx large, greenish yellow, resembling that of *C. Pavonii* and its allies, which are, however, very different in their habit and foliage. Mr. W. Lobb sent seeds of this from Peru to Messrs. Veitch & Sons, of Chelsea, who succeeded in raising it; and it was figured in the Botanical Magazine, 1859, t. 5154.

8. *C. bicolor*.—A diffusely branching undershrub, with ovate coarsely-toothed stalked leaves, 2 in. to 3 in. long, and yellow and white flowers of medium size, remarkable for the lower lip being curved completely over the upper very small one. A native of Peru, whence Mr. Cruckshank sent seed about the year 1830. It is figured in the Bot. Mag., t. 3036, under its right name, and in the Bot. Reg., t. 1374, under the name of *C. diffusa*. Mr. T. Smith says this makes a useful greenhouse plant in winter, if grown on freely during the previous summer. There are upwards of half-a-dozen others of the same section, of which one at least, *C. flexuosa*, described above, is more ornamental.

9. *C. verticillata*.—A diffusely branching, half-shrubby species having slender, hairy branches, clothed with ovate, sharply serrated leaves, from 1 in. to 2 in. long and terminating in a narrow spike of lateral clusters of small, deep yellow flowers. The corolla is peculiar in the upper lip being altogether suppressed, and in the lower one being very slender at the point of attachment, and produced upwards in a curved, inflated pouch. Introduced from Lima in 1830 by Mr. Cruckshanks and figured in the Bot. Mag., t. 3094, under the erroneous name of *C. angustiflora*. It is more curious than beautiful.

10. *C. thyrsoidea*.—This and *C. alba*, among suffrutescent species, have a remarkably slender, erect habit of growth, and the stems are crowded with linear, coarsely toothed leaves, usually not exceeding 1 in. in length in this species, though there are forms having leaves intermediate in length between these and those of *C. alba*, which are 2 in. long; hence they may be varieties of one species, for there is little, if any, difference in the flowers, except colour. The inflorescence is long, narrow, and dense, and the nearly globular, deep yellow flowers are from a third to half an inch in

diameter. A common species in Chili, where it bears the name of *Palpe*, and is used for dying yellow. It was introduced in 1828 by Dr. Gillies, and it is figured in the Bot. Mag., t. 2915, where it is stated that the blossoms have a slight fragrance, not unlike that of the flowers of the *Laburnum*. This, it is recorded, has hybridised with *C. Fothergillii*, particulars of which are given under that species.

11. *C. alba*.—An undershrub with the habit, foliage, and flowers of *C. thyrsoidea*, save that the leaves are longer and the flowers white. A very pretty species, raised by Messrs. Veitch from seeds sent to them from Chili by Mr. W. Lobb before 1844, and figured in the Bot. Mag., t. 4157. It is said to be rare in its native country.

12. *C. adscendens*.—This species is, or rather was, better known to gardeners under the name of *C. rugosa*, Bot. Reg., t. 1588, though it had previously been published in the same magazine, t. 1215, under the above name. *C. crenata* (Bot. Reg., t. 790) is merely a slight variety of the same species. It is one of the sub-shrubby, yellow-flowered species that has been used for bedding, though by no means the best. The stems are rather slender with a reddish tinge, and the leaves small, rough, and sharply toothed. Introduced from Chili in 1823.

13. *C. sessilis*.—Allied to *C. integrifolia*, but a more shrubby plant, with distinctly sessile leaves, broadest at the base, and woolly stems, at least, when they are young. A native of Chili, introduced by Mr. Cumming in 1831, and figured in the Bot. Reg., t. 1628. Flowers deep yellow, the upper lip of the corolla two-thirds the size of the lower, and applied to it.

14. *C. dentata*.—Near *C. adscendens*, but having longer leaves, less harsh to the touch and more finely toothed, and larger, more numerous flowers. It is figured in the Bot. Reg., t. 1476, under the name of *C. chilensis*. It was sent from Chile by Mr. Anderson, who was the botanical collector attached to Captain King's expedition. This and *C. adscendens* were probably both concerned in the parentage of the hybrid bedding varieties. *C. andina* is a closely allied species inferior in point of beauty; it was formerly in cultivation and is figured in the Bot. Reg., t. 1576, under the name of *C. Herbertiana* var. *parviflora*.

15. *C. viscosissima*.—This, in many respects, looks like a broad-leaved variety of *C. integrifolia*, and it was published as such in the Bot. Mag., t. 3214; but Lindley subsequently published it as a distinct species, Bot. Reg., t. 1611. In gardens it was called *C. rugosa* macrophylla, and it is recorded that it was raised from seed by Mr. Cameron, of the Birmingham Botanic Garden, but nothing is said respecting the origin of the seed. It is a robust, exceedingly viscid plant, with broad leaves and tawny flowers.

16. *C. integrifolia*.—This, above all others, is the bedding *Calceolaria*. It is an exceedingly common Chilean plant, varying considerably in the width and toothing of the leaves, and in the degree of viscosity of the stems and leaves, as well as in the size and tint of its flowers. The name *integrifolia* is not an appropriate one in the sense it is now generally understood, because the leaves, although undivided, are always toothed. It appears to have been first introduced by the Horticultural Society, in 1822, and figured in the Bot. Reg., t. 744. This has rather broad leaves, whitish underneath, and not unlike those of *Sage*. Plate 1803 of the same work represents a narrow leaved (*angustifolia*) variety; both have bright lemon yellow flowers, with the upper lip of the corolla half the size of the lower, and closely appressed upon it. *C. rugosa*, Bot. Mag., t. 2523, seems to be a variety differing in the tomentum on the under surface of the leaves, being of a rusty colour and in the flowers being of a deeper yellow. There are several other synonyms of the species.

17. *C. crenata*.—This is figured in the Bot. Mag., t. 4154, under the name of *C. floribunda*, and differs from typical *C. amplexicaulis* (figured in the same work, t. 4300) in the leaves being rounded not cordate, and stem-clasping at the base, and in the flowers being of a paler yellow, but, at the most, it can only be a slight variety of the same species. It was sent to Messrs. Veitch, from Chili, by W. Lobb, in 1843.

18. *C. amplexicaulis*.—A few years ago this was almost as familiar in the flower garden as *C. integrifolia*. It is the one with soft, dark green leaves clasping the stem, and a profusion of pale yellow flowers. It is true the Bot. Mag. figure, t. 4300, represents rather a deep yellow almost orange flowered variety, under this name, and a pale yellow one, which I take to be a variety of the same, under the name of *C. floribunda*, here given under *C. crenata*. *C. amplexicaulis* inhabits Peru and Ecuador, and was introduced by Mr. W. Lobb about thirty years ago.

Herbaceous Perennials.

19. C. Pavonii.—This is one of a group of about six herbaceous species, remarkable for their robust habit, large, coarsely toothed leaves, with usually a triangular blade and broadly winged perfoliate petiole, and for their very large calyx. *C. Pavonii*, Bentham, Bot. Mag., t. 4525, is a native of Peru, and is first cultivated in this country, it appears, by Messrs. Lucombe, Pines & Co., of Exeter, in 1850. It grows 3 ft. to 4 ft. high, and is everywhere covered with more or less glutinous hairs. The leaves in luxuriant specimens are upwards of 6 in. long, the triangular cordate blade about half of it, and the wing of the petiole increases in width downwards, the wings of the two opposite leaves being connate at the base, thus encircling the stem with a broad, leafy expansion. The showy buff yellow flowers are borne in terminal and lateral corymbs, the entire inflorescence being large and effective. The pale green calyx has spreading sepals 2 in. from tip to tip; the upper lip of the corolla is nearly flat and disk-like, and the lower one is nearly orbicular, very much inflated, about 1 in. in diameter, and curved upwards against the upper one. Mr. T. Smith writes: "This forms handsome specimens, 3 ft. or 4 ft. high; it commences to bloom in the autumn, and continues through the winter; and it is a most distinct and desirable conservatory plant for this season when striking flowering plants are scarce." The other species of this group are *C. tomentosa*, a very woolly plant with ovate leaves; *C. calycina*, remarkable for its yellow calyx, as large as that of *C. Pavonii*, and for its flowers being in umbels or trusses like a *Pelargonium*; *C. perfoliata*, this also has a yellow or greenish yellow calyx and subumbellate flowers, but the flowers are smaller than those of the last, and the blade of the leaf is broader at the base; finally, *C. dilatata* is relatively a very slender plant with smaller leaves and flowers; they all inhabit the same region as *C. Pavonii*.

20. C. piscacensis.—One of the most distinct species of the genus, having leaves something like *C. amplexicaulis*, but easily distinguished from all others hitherto introduced, by its large brilliant orange red flowers. It is a tall, robust, herbaceous perennial, with deeply toothed, rough leaves, recurved at the margin, and a succession of shortly stalked cymes of flowers in the upper part of the stem, forming together an inflorescence 6 in. to 9 in. long. The upper lip of the corolla is small and concealed by the lower one, which is abruptly bent upon itself and over the upper one. Introduced by Messrs. Veitch from Peru through their collector, Mr. Pearce, and figured in the Bot. Mag., 1867, t. 5677.

21. C. lobata.—An ascending or trailing, branched, more or less glandular pubescent herb, with roundish, cordate lobed leaves, about 2 in. in their greatest diameter, and borne on relatively long petioles; flowers clear yellow spotted with red inside, and arranged in loose panicles. Upper lip of the corolla small; lower one large, saccate, suddenly bent upwards about the middle, and recurved on itself. Mr. Smith says, "this flowers in the freest possible manner all through the autumn, winter, and spring months, and is a most useful basket plant, or to hang over the edge of the greenhouse stage." I have seen no record of the date of introduction of this species, but it is figured in the Bot. Mag. for 1877, t. 6330, from a plant furnished by Messrs. Veitch. It is a distinct and attractive species, native of the mountains of Peru.

22. C. crenatiflora.—Although an old name, the species to which it properly applies was published in Sweet's Brit. Fl. Gard., 1852, second series, t. 155, on its introduction into this country under the name of *C. pendula*. A better figure of it may be seen in the Bot. Mag., t. 3,255. It is a robust plant, with larger stem leaves than *C. corymbosa*, and equally as large flowers, which are yellow dotted with red. The calyx is relatively large, the upper lip of the corolla very small, and the lower one large and saccate with a small opening and notched and grooved in its lower part. There seems to be indications in some strains of hybrid *Calceolarias* that this species was concerned in their production, particularly in the long, pendent, grooved, and crenate corolla. According to Gay it affects humid situations in its native country, Chili. *C. glandulosa* is an allied species, with small yellow or white flowers.

23. C. racemosa.—This is a herbaceous species, closely allied to *C. corymbosa*, but inferior as an ornamental plant. It is a Chilean plant, and was in cultivation in this country in 1830, when it was figured in the Bot. Mag., t. 1,313, under the name of *C. Herbertiana*.

24. C. corymbosa.—One of the parents of the hybrid race, and the one whose characteristics are most prominent in the strains cultivated at the present time. This species gave size to the flowers, the yellow element in colour, breadth to the leaves, and robustness in habit; whilst *C. purpurea* and *C. arachnoidea* gave shape and the other colours to the flowers. *C. corymbosa* was introduced from Chili about the year 1822, and was figured in the Bot. Reg., t. 723,

from a plant raised in Lady Tankerville's garden at Walton-on-Thames. It has large, oblong, rich yellow flowers, with a large opening to the lower lip. The commonest species in Chili, ranging from Coquimbo to Valdivia, Valparaiso, Santiago, &c. The following is a condensed account of the history of the early hybrids of the herbaceous class. *C. Youngi*, Bot. Reg., t. 1448, was the first hybrid of this class of which a coloured plate was published, if not actually the first one raised. Further particulars respecting this will be found under *C. arachnoidea*. In London's "Gardeners' Magazine" for 1830, p. 493, it is stated, in an extract from the "Edinburgh Philosophical Journal," that Mr. Morrison, gardener to Lord President Hope, Granton, being aware that several of the finest species of *Calceolaria* were shy in producing seeds, suspected that this defect might be corrected by applying the pollen of certain kinds to the stigmata of others; and he first has had the merit of presenting to the florist hybrids thus produced, which equal if they do not surpass in beauty any of the species. Mr. Morrison succeeded in intercrossing *C. corymbosa*, *C. arachnoidea*, *C. plantaginea*, and *C. Fothergillii*. In the same periodical, 1832, p. 43, it is stated that Messrs. Young purchased the stock of these Scotch-raised hybrid *Calceolarias*. In July, 1831, Messrs. Young exhibited some of them, as well as their *C. Youngi*, at the Horticultural Society's Rooms. In 1832, Mr. Atkins, nurseryman at Northampton, sent a beautiful hybrid which he had raised to London, who states, Gard. Magazine, 1832, p. 473, that it was very much like *C. Youngi*. It was figured in Sweet's "British Flower Garden," second series, plate 168, under the name of *Akinsiana*. Plate 162 of the same work is a representation of *C. Martiana*, the variety mentioned under *C. Fothergillii* as being a hybrid between that and *C. corymbosa*. It certainly has the long flowers with the very open lower lip of *C. Fothergillii*, but there are wild specimens of *C. corymbosa*, itself a very variable species in a wild state in Kew Herbarium, almost exactly like the plant represented, and, although it is stated that *C. Fothergillii* was the female parent, it is possible that there was some mistake. The two species are so very different that one would not expect them to intercross. Another hybrid, *C. Wheeleri*, Sweet's "British Flower Garden," second series, t. 130, was raised by Mr. G. Wheeler, nurseryman, Warminster, from a hybrid between *C. purpurea* and *C. corymbosa*, fertilised again by *C. purpurea*. It has small, though regular, inflated flowers of a rich dark red. To complete the history of hybrid *Calceolarias* would occupy too much space, and probably interest only a few readers; suffice it then to say that the idea having once been made known, the earliest hybridisers soon found imitators all over the country, improvement succeeded improvement, and the first hybrid varieties which were originally sold at high prices soon became valueless.

25. C. arachnoidea.—This species deserves our attention, because it was one of the parents of the earliest hybrid herbaceous *Calceolarias*. It is a remarkable and very distinct species, with large leaves, in shape like those of the hybrid, but clothed with a silvery, dense, felt-like down. The flowers are of a rich purple, but somewhat crumpled and rather irregular in shape. It is a native of Chili, and was introduced to this country about the year 1827. There are figures of slightly different varieties of this species in the Bot. Mag., t. 2374; and the Bot. Reg., t. 1454. This species is of some economic importance in its native country, as its roots furnish a red dye, superior, Bridges states, on a label in Kew Herbarium, to Brazilian wood for its fine colour and durability. Dr. Gillie's note respecting this species in the Bot. Mag., plate 2925, seems worth reproducing here. "The *Calceolaria*," he says, "described by Dr. Graham, under the name of *C. arachnoidea*, and to which I had assigned the specific appellation of *C. tinctoria*, in consequence of its utility in dyeing, I first found near the silver mines of San Pedro Nolasco, on the summit of the mountain so called, near the junction of the river Mapu, with the Rio del Yeso and del Volcan. On a subsequent journey across the Cordillera, further to the south, and opposite to San Fernando, I also met with it in abundance growing in the most elevated valleys which I visited in the vicinity of La Casa de las Damas. Here many people were employed in digging up the roots, which they dry and collect in bundles for sale. In Chili, where this plant is in great use, under the name of *Reibun*, for dyeing woollen cloths of a deep crimson colour, the alum earth employed as a mordant in this process is obtained abundantly from a mountain in the neighbourhood. This plant grows in hard gravelly soil, where the fibrous roots penetrate in all directions a circumstance which renders the collecting of it to any considerable extent a work of time and labour." Gay, "Flora Chilena," p. 182, states that it is common in the mountains of Chili, from Coquimbo to Concepcion. *C. cana* is a closely allied species, with yellow flowers the roots of which are also used to dye red. With regard to the part of *C. arachnoidea* has played in the production of the hybrid race of herbaceous *Calceolarias* which has now been brought to such per-

fection, we have fortunately the best of evidence. Plate 1,413 of the "Botanical Register" is a representation of C. Youngi, which, it is there stated, was raised in 1830 by Messrs. Young, of Epsom, from a plant of C. arachnoidea impregnated with C. corymbosa. It is a very pretty variety, in which the colours of the flowers of the two species are combined, but the plum purple or reddish violet of C. arachnoidea is intensified into a very dark purple brown, the whole of the top of the lower lip being of that colour and the rest yellow. Further details respecting the parentage of hybrid herbaceous Calceolarias will be found under C. corymbosa and C. purpurea.

26. C. purpurea.—An erect herbaceous species, with leafy stems from 1 ft. to 2 ft. high, terminating in large, loose corymbs of numerous small, lilac-purple flowers. The stalklike leaves are coarsely toothed, rough to the touch, and more or less glutinous. The flowers are about $\frac{1}{2}$ in. in diameter, both lips of the corolla inflated, the upper one about half the size of the lower, and closing like a lid over the opening of the lower lip. Seeds of this species were sent by Mr. Crickshanks from Chili to Edinburgh and Glasgow in 1826. It appears to have been one of the parents of some of the early hybrids, but there is hardly any trace, if any, of it in the race of hybrids now cultivated. For particulars respecting these early hybrids, see under C. corymbosa and C. arachnoidea. There is a very pretty and singular Calceolaria figured in Sweet's "British Flower Garden," second series, t. 244, under the name of C. purpurea var. picta. It was supposed to be an accidental variety of C. purpurea, from which it differed in nothing except the colour of its flowers, and it was raised by Mr. Wheeler, nurseryman, of Gloucester. The flowers are white, with a band of bright purple around the opening of the lower lip, the purple shading off gradually downwards into the white; within, and on the margin of the opening, they are yellow.

27. C. Fothergillii.—A tufted, herbaceous perennial with small obovate-spathulate, glandular leaves, and leafless flower scapes about 6 in. high, and bearing one flower each. A singular plant reminding one of a Butterwort (Pinguicula) by its habit and inflorescence. The flowers vary in colour, but they are some mixture of yellow and purple brown; lower lip of corolla about 1 in. long and very open; upper lip reduced to a small disk. This is one of the prettiest and hardiest of the genus, being a native of the Falkland Islands and Patagonia. It was introduced from the former country in 1777 by Dr. John Fothergill, and it is the subject of one of the few plates which adorn the first edition of Aiton's "Hortus Kewensis," and it is t. 348 of the Bot. Mag. This and its allies should be treated as Alpine plants. There are numerous species of the same group equally interesting, but few if any of them are in cultivation. They inhabit the same region and would be hardy in this country under suitable conditions as to soil and moisture. C. nana is a miniature of C. Fothergillii, growing not more than 2 in. or 3 in. high. C. Darwini is a very handsome species of this group, with flowers nearly twice as large as those of C. Fothergillii. If the operators were not mistaken, C. Fothergillii was one of the parents of some of the earliest raised hybrids. Thus in London's "Gardeners' Magazine," 1831, p. 510, it is recorded that Miss Martineau exhibited at the Horticultural Society, a Calceolaria raised from seed of C. Fothergillii, fertilised by C. corymbosa. There is also a very pretty Calceolaria figured in Maund's "Botanic Garden," VII., fig. 595, and it is recorded that this beautiful variety of Calceolaria was raised by Mr. Thomas Williams, gardener to John Willmore, Esq., of Oxford, near Birmingham, from seeds of C. Fothergillii, the flowers of which had been fertilised by pollen of C. thrysioides. This variety was afterwards sent out under the name of C. pardanthera. Judging from Maund's reduced figure it must have been a very handsome variety.

28. C. plantaginea.—Herbaceous, with tufted leaves, not unlike those of the Ribwort Plantain (Plantago major), and very slender, erect, leafless flower stems, 6 in. to 9 in. high, and bearing two to four yellow flowers. One of the numerous species introduced from Chili, in 1826, by Mr. Crickshanks, and cultivated for a time. There is a figure of it in the Bot. Mag., t. 2,805. The corolla is nearly hemispherical and yellow, elegantly dotted with red underneath. C. Hopeana, figured in Paxton's Mag. Bot., ii., p. 265, is said to be a hybrid between this and the very different C. corymbosa.

29. C. tenella.—A pigmy, herbaceous, decumbent species, about 3 in. high, spreading and rooting at the joints; stems thickly clothed with small Thyme-like leaves. Flowers yellow with a few red dots or lines about $\frac{1}{2}$ in. long; both eyes of the corolla sacate, the lower one three times as large as the upper. A very pretty species for the rock garden, introduced from Chili by Mr. G. Downton for Messrs. Veitch, and figured in the Bot. Mag., t. 6,231.

Annual Herbs.

30. C. petiolaris.—A tall, branching, herbaceous plant; stems glandular, leafy; leaves ample, stem clasping, and coarse; flowers

numerous, small, yellow, in loose corymbs; calyx relatively large; corolla about $\frac{1}{2}$ in. in diameter; upper lip nearly as large as the lower, and pressed down upon it. This species was cultivated in the Horticultural Society's Garden, in 1827, from seeds received from Chili. It is figured in the Bot. Reg., t. 1,214, under the name of C. floribunda, and in the Bot. Mag., t. 2,876, as C. connata. Judging from the roots of dried specimens, this species is of annual duration. Luxuriant specimens grow 3 ft. to 4 ft. high, and have quite stout stems. It possesses no special ornamental character.

31. C. pinnata.—A slender annual from 6 in. to 1 ft., or occasionally higher, having elegantly cut foliage, but small, inconspicuous yellow flowers. Although the leaves of this species are very beautiful, it is rather a weedy plant, and would be cultivated more as a curiosity than for ornament. It is interesting as being the first species of the genus cultivated in this country. Introduced from Peru in 1773, through the agency of Sir Joseph Banks, and figured in the Bot. Mag., t. 41. It has become naturalised in India, and last year I saw a specimen of it which had been found growing wild in Sussex. No doubt the seed had been conveyed with some garden refuse to the spot where the plant was found.

32. C. chelidonioides.—As its name implies, this species resembles the Celandine, Chelidonium majus. It is an annual, from 1 ft. to 3 ft. high, with elegantly cut foliage and rather large, yellow, almost globose, flowers. A native of Peru, growing in ditches, on the banks of streams, and moist, shady situations generally. It was cultivated in British gardens some years ago, and there is a woodcut of it in Paxton's Fl. Gard., iii., p. 143.

33. C. mexicana.—A slender, yellow-flowered annual, growing at a great elevation in the mountains of Guatemala and Mexico, the northern limit of the genus. C. gracilis and C. tenuis are allied species natives of Peru. They are scarcely worth cultivating for any ornamental character which they possess, especially now when the choice of more showy, more elegant, and more lasting annuals is so very extensive.

34. C. scabiosæfolia.—A Peruvian annual, resembling C. pinnata, but of much coarser habit and even less ornamental. Cultivated in England in 1823, and figured in the Bot. Mag., t. 2,405.

W. B. HEMSLEY.

STORING ICE.

In order to prevent any misunderstanding, allow me to say that the icehouse recommended by Mr. Williams (p. 161) represents a stack built on the principal of a cone, and with a thick column of straw bundles up the centre of it, which, we are told, is to provide for drainage there, but where, it can be demonstrated both theoretically and practically, no melting takes place, and no drainage is needed. His central column of straw is neither more nor less than a clear waste of space, and a channel for heat to waste the ice. Mr. Williams himself furnishes the best argument against central drainage when he says (p. 227) that water poured on the top of the stack "will, by contact with the ice, be almost immediately congealed, and will never percolate to the bottom." Could a better argument be furnished against draining the centre of the heap? If water "never percolates to the bottom," even when it is poured on the heap, what do we want with a funnel up the centre? How also does Mr. Williams reconcile this statement with another (p. 239) that he has seen the water from wasted ice standing "as in a bowl" on the top of the ice? I never witnessed such a phenomenon. A stack of the shape which he has given never wastes with a flat top, but melts pretty evenly all round, leaving the sides of the house from top to bottom, and retaining its original shape till the very last fragment

disappears, unless it has been interfered with. But people do not take the ice from off the top of the heap if they can help it, but from the side, hence the custom of having a side door in most ice houses. In conclusion, I may say that I never stated that a cone contained more than any other figure in proportion to its "height"—"bulk" was the word used by me, and, of course, I also meant a cone of a height in proportion to its base, or, in short, a heap such as we usually build in our ice houses. In speaking of the cubic contents of any body, I did not suppose it was necessary to be more explicit. "Where," asks Mr. Williams, "is the outer surface of a cellar of ice wholly below the level of the ground?" I reply that the outer surface is where he tells us to place the straw, whether the heap be above or below ground. C.

INDOOR FRUIT GROWING FOR MARKET.

(Continued from page 214.)

GRAPES.—In small gardens at the back of villa residences—of which Mr. Sweet's, at Leyton, is a good example—Grapes are sometimes grown most successfully. In such cases the borders are inside—outside borders taking up too much space where the extent of ground at command is limited; and, moreover, in the case of early houses, the borders would require to be warmed by means of fermenting material of some kind, and this cannot well be afforded, especially in places where it cannot afterwards be made use of in the way of enriching vegetable ground. In a few cases, however, there is a narrow border outside the houses in which the roots are allowed to ramble; but these are principally confined to late or mid-season houses. The rod and spur system of training is the one adopted in such cases, and the chief aim of the proprietor is to get the wood thoroughly ripened previous to pruning; this end attained, success becomes almost a certainty. In pruning, the shoots are not cut closely into the old wood, but a good plump bud, which is almost certain to produce a large bunch of Grapes, is left on each spur, and, should any of the back eyes break, the one bearing the best bunch is selected to remain and the rest are removed. When the spurs become long and scraggy, one or two of the rods are cut down each year and replaced by young ones run up, and in this way strong, healthy, fruit-bearing canes are always maintained. Some of the Vines have two, three, or four rods each—others only one. In some cases the Vines are planted on each side of the house, each row furnishing one-half; but in others only one side is planted, and the canes trained so as to cover the whole of the roof. This latter plan is an excellent one, as, when requisite, fresh Vines can be planted on the vacant side, without in any way disturbing the roots of existing ones; moreover, the newly-planted Vines can be allowed to get well established before the older ones are discarded, and thus neither Vines nor crops are sacrificed. The chief kinds of Grapes grown here are Black Hamburgh, Muscat of Alexandria, Black Alicante, Lady Downes Seedling, and a few Gros Colman. The two former kinds are started in November and December, and furnish ripe, marketable fruit from late in May until the end of August. Gros Colman furnishes fruit during the early part of the autumn and, indeed, up to Christmas; and Lady Downes and Black Alicante keep up a supply until February. Late Grapes are always left on the Vines until sent to market, the mode of keeping them in bottles of water, that of late years has come into practice in private establishments, being too troublesome for market growers. A piece of paper is, however, tied over the top of each bunch to preserve it from damp and dust, and a dry, airy atmosphere is always maintained in the house as long as the Grapes are hanging there. Such Grapes realise in the market from 6s. to

7s. 6d. per lb. Watering is an operation to which Mr. Sweet pays unremitting attention. Each house is watered four times during the season, as a rule, and at each application sufficient is given to thoroughly saturate the whole of the soil down to the drainage. The first watering is usually given immediately the Vines are pruned, this being to compensate for the long season during which the roots have of necessity been kept in a dry state in order to keep the fruit in good condition, as water applied to the roots of Vines after the fruit is ripe impairs the flavour of the produce, as well as its keeping properties. The second dose is given when the leaves become expanded, the third when the fruit is fairly set, and the fourth when stoning is completed. If very dry weather prevail, and another watering become necessary, it is supplied just before colouring commences. Manure water is at all times liberally supplied, even when the Vines are first started, and to this may be attributed in a great measure the unusual strength which the shoots attain, even in the dull sunless season. Indeed, to the effectual mode of watering is attributed in no small degree the almost marvellous results obtained in this establishment. All Grapes sent from here are of the best quality, although the Vines are very heavily cropped. Indeed, as a Grape grower, Mr. Sweet is excelled by few who grow entirely for market. Young Vines planted in autumn make canes the following summer as thick as a good-sized walking-stick, and the following season are allowed to carry a moderate crop of fruit. Alicante grafted on stocks of Muscat of Alexandria give great satisfaction in this establishment, where they yearly bear large and perfect crops of fruit. Whenever a house of Vines is found to be on the decline as regards bearing qualities, young Vines are speedily substituted for the old ones; half measures, such as trying to recruit the old canes, being, in the case of market growers, simply a waste of time and money.

Another very important Grape-growing establishment, notice of which must not be omitted, on account of the large Grape Vine to be found in it, is that of Mr. Kay, of Finchley. Grapes are grown here to a considerable extent and "the large Vine at Finchley," as it is called, is well known to all Grape growers. This Vine has produced remarkable crops of fruit every year since it became established. The house—a span-roofed one—in which it is growing has on several occasions been lengthened in order to afford additional room; it is now 90 ft. long and 18 ft. wide—a space entirely occupied by this Vine, which enters the house on one side about the middle. Its main stem, which measures at the bottom nearly 2 ft. in circumference, crosses the roof, and from this issue ten strong rods, half of which are trained each way horizontally. On this Vine, when visited in August, 1877, there were nearly 500 well-formed bunches of Grapes, each of which averaged about 2 lb. in weight. The border, like that of other Vineries here, is outside; it is about 15 ft. wide and 4 ft. deep, made on a hard, clayey bottom, on which is placed a quantity of brick rubbish, &c. for drainage; the soil consists of ordinary loam and brick rubbish, such as can be obtained in any place where building is going on. No manure was mixed with the soil before the Vine was planted, but the border receives an annual top-dressing in autumn to protect the roots during winter and spring, and from this the roots, no doubt, derive considerable nourishment. As regards pruning, the spur system is that adopted; the wood is thoroughly ripened every year by exposing it freely to air and light, and, could the house and border be further enlarged, this Vine would, doubtless,

become one of the very finest in the Kingdom. Its fruit is usually fit for use in September, after that from earlier houses is finished. Amongst late Grapes here a house of Lady Downes Seedling and Black Alicante deserves notice. It is a low, lean-to structure of considerable length, and has a northern aspect—a position in which the fruit is found to ripen equally well as that in a more sunny situation, and, being later in ripening, it can be preserved in good condition for a long time, provided the atmosphere of the house is kept dry and airy. Most of the Vines consist of from four to five canes each, old ones being removed as often as it is considered expedient to replace them with young ones. As soon as the Grapes are cut, the houses are thrown open, and the Vines exposed to the full influence of the weather. This has the effect of ripening the wood thoroughly and of clearing the foliage of insects should any exist. Most of the canes in the late houses are allowed to carry from twelve to fifteen bunches each, all of which they ripen perfectly.

Vinery, Peach, and Plant House combined.

Mr. Elliot, of Fulham, to whom allusion has already been made, grows mid-season and late Grapes only. His Vines are all planted in outside borders, which are heavily mulched with manure throughout the year. When I visited this establishment, the Vines had only been planted a few years, and were, consequently, not thoroughly established. It is remarkable how much more quickly market gardeners fill their houses with Vines than private growers. Canes planted here filled the houses in two years, and the third season they carried excellent crops. Vines of the Black Alicante variety planted in a house with a northern aspect made remarkable growth the first season and thoroughly ripened it, and they will in all probability succeed equally well as if they were in a house with a southern or eastern aspect, which most people contend is indispensable to the production of well-coloured Grapes. Black Hamburgh, Gros Colman, and Black Alicante are the only varieties grown in this establishment. They are not (as before stated) forced, but are allowed to advance naturally, fire-heat being applied only to dispel damp or prevent the tender shoots from receiving severe checks by sudden changes in the weather should they occur. The varieties

come into use in the order named, and, as fruit of the best quality only is produced, it accordingly realises high prices. The Hamburghs are usually fit for market by August, and fetch from 4s. to 5s. per lb. Gros Colman, in September, October, and November, realises from 6s. to 9s. per lb.; and Alicantes, in mid-winter, from 6s. 6d. to 7s. 6d., according to the demand there may be for them. Whilst the Vines are at rest, scarlet Pelargoniums, Mustard and Cress, Tarragon, &c., are grown under them.

Mr. Yeldham, of Fulham, grows Grapes to a large extent, his object being quantity rather than quality, in order to meet the demand of a second-class trade; his houses are, therefore, not wholly devoted to Grape growing. Of these he has altogether twenty, ranging in length from 100 ft. to 250 ft. and proportionately wide. The Vine borders here, as elsewhere, are all outside, well drained, heavily manured during the winter, and copiously watered during summer. Most of the Vines, which have been planted for a number of years, are trained on the rod and spur system, several canes being allowed to each Vine. One large house is, however, pruned on the long rod system, which consists in training up young canes every year and removing them as soon as they have borne a crop of fruit. By this method, a crop of large bunches of Grapes is almost a certainty; but, Mr. Yeldham remarks, they do not always colour so well as those produced on older canes. Black Hamburgh is the only kind grown here, and this variety serves both for early and late crops. The earliest houses usually ripen their fruit late in May and early in June, and others are brought on in succession. As very large bunches and berries are not sought after, the bunches are thinned much less severely than would otherwise be the case, and a greater number of bunches are left on the Vines. Grapes of this description, owing to their cheapness, find a readier sale than those which are brought to the highest state of perfection. The principal late Vinery is a span-roofed one, 220 ft. long, and, before the railway ran through the grounds, taking away part of it, this house was nearly double that length. A pathway runs inside along the front, and at the back is a border from 12 ft. to 15 ft. wide, planted with Camellias. Another very profitable kind of house—of which the accompanying illustration will give some idea—is one which, at some time must have been a shed. A glass front and roof have, however, been fixed in it, the spars, rafters, and boarded back remaining unaltered. The upright posts which support the ends of the cross rafters are about 12 ft. apart, and at the foot of each of those next the glass front is planted a Vine, the main shoots of which are trained horizontally along the cross rafters, and from this main stem issue at every 2 ft. or so other rods, which are trained in an upright position towards the roof. By this means the Vines obstruct very little light from other subjects grown in the house, whilst they themselves have abundance of light and sun from every side. In the centre of the house, and between these Vines are planted standard Peach trees, which are from 12 ft. to 15 ft. high, and as much through, and during June and July their branches bend under the weight of good-flavoured and well-coloured fruit, which they bear. The trees are never pruned, but in every respect liberally treated, and they amply repay the trouble bestowed upon them. Peaches and Nectarines during June and July realise from 10s. to 15s. per dozen, according to size and quality. The house in question is 215 ft. in length, and 28 ft. in width; the back boarded wall is covered with Gloire de Dijon Roses, one plant alone furnishing 150 ft. of the space. A number of Camellias and several large specimens of Mock Orange

are also growing in this house, the latter yearly bearing immense quantities of sweet-scented white blossoms, which are eagerly bought up by bouquet makers. All available space on the floor and between the trees is occupied by Rhubarb, and in February and March there is such a quantity to be gathered that one wonders how it could all be disposed of so early in the year. A more profitable or interesting house than this, it would be difficult to meet with; indeed, so simple is it in the way of arrangement, and so inexpensive as regards labour, that it is surprising that other fruit growers have not adopted similar ones. From this house alone Mr. Yeldham cut in one year 7300 bunches of well-ripened Grapes.

Grape growers for market differ from private growers in their methods of culture in several particulars. For instance, they do not stop the shoots at one or two joints above the bunch, but allow three, four, and, if there be room in the house, as many as five and six joints. By this means they get plenty of foliage, and they can crop the Vines much heavier than they otherwise could do. Syringing the foliage is not so much practised by market growers as by private cultivators, as they are of opinion that heat and too much moisture together render the foliage thin and poor, thus injuring the crop. Thinning, which is completed at one operation, is always performed as soon as the berries are well formed. This practice saves labour and the results are found to be as good as when the bunches are gone over twice or thrice. Abundance of air, all the light possible, plenty of water, and a growing temperature are the chief points observed in the general cultivation of the Vine in market gardens.

C. W. S.

THE FRUIT GARDEN.

FRUIT PROSPECTS.

SELDOM have these been brighter than at the present moment (March 25). The two principal elements in the matter are the numbers and the lateness of the buds. With a winter of almost unexampled length and severity, running through March with about 10° of frost and a cold north-east wind, most of the fruit buds are now as soundly asleep as they are in most seasons in the middle of February; it follows, that unless April proves far more genial and exciting than usual, the probability is strong in favour of the fruit buds being so late as to escape the killing severities of late frosts. The destructive power of these arises more from the tenderness of the prematurely-developed buds than from the actual amount of the frost itself; hence, every week longer that fruit buds remain closed the prospect of the fruit season brightens. The buds, as I have said, are also abnormally numerous as well as late. Several years' partial rest, and, upon the whole, a favourable autumn for the maturation of the wood last season, have enabled the trees to recruit their strength and mature a plentiful crop of fruit buds. The fear has been expressed in certain quarters that the severe frosts of the past winter may have injured the fruit buds, but this does not seem to have been the case to any extent. The winter has been one of great steadiness of character as well as severe cold. There has been far fewer fluctuations of temperature and of sun and shade than usual. It is the sudden changes rather than any mere intensity of cold that proves most injurious to fruit buds. With leaden skies and almost continuous frosts for three months at a stretch, the buds wintered well. Hence their present safety and the prospect of a plentiful season. It is well, however, to make security doubly sure by adopting some of the more simple means of protection. After trying everything, from glass, slate, and wooden copings of different widths, and all kinds of textile fabrics, portable and fixed, it may seem somewhat humiliating to have to come back to the conclusion that the simplest and most primitive means of protection are by far the best. These consist of the thrusting of a few Fern

fronds, Asparagus tops, and a few loose handfuls of straw, or spraye boughs, among and over the flowering shoots. The protection is thus placed close to the flowers. This method of protection creates no currents or draughts. Such protecting screens, when formed of Spruce or other boughs, have also this great advantage; the screen removes itself piecemeal, a leaf at a time, as it were, and by the time the more genial weather enables the embryo fruits to take care of themselves, nothing of such screens is left but a few bare skeleton boughs, which obstruct but little light and scarcely injure the trees. With the ordinary run of seasons such as we have had of late years, it is hardly safe to remove these wholly till the end of May. But so much and so gradually do such protectors remove themselves, that it is possible to disbud the trees before finally removing the whole of the self-reduced protectors. These simple methods may be adopted alone, or in conjunction with glass or other copings. Last season, while Peaches, Nectarines, and Apricots were wholly destroyed, protected with glass copings faced with canvas or screened with netting, the trees screened with boughs under the copings carried a full crop, and the trees themselves also came through the ordeal of the last trying spring unharmed. Similar simple means of protection are equally effective for cordon Plums, Pears, and Apples, and they are easily applied to such trees. A few bushy boughs laid over or on, have never failed to ensure a crop of Plums on cordons, and saved a capital crop of Apples on cordons last season, while all others, with few exceptions, were cut off by the severe weather of the last spring. In most large gardens such protecting material costs nothing, and it is as efficient as it is simple and cheap.

D. T. FISH.

POT VINES.

"A. D." has done good service in directing attention to the evil practice of placing pot Vines out-of-doors, a plan generally adopted in nurseries. Pot Vines grown for forcing purposes (I am assured by the most extensive growers in London and elsewhere, that most of their stock is sold for that purpose) cannot have too long and too favourable a season under glass in this country, in order to fit them for starting readily in November and December. I find, and all with whom I have talked on the subject find, that when they grow their own pot Vines, and get them ripe and pruned by August, or, at the latest, by September, they can get them to start with comparative ease in November, and get their crops in early without too much pressure at the end; but nursery-grown Vines that had been put out-of-doors about midsummer "to ripen" as it is termed, never can be got to start readily, simply because they are not ripe enough to prune early, and therefore, they get no rest between pruning and starting. We grow our own pot Vines when we can afford the room, but quite as often we have had to buy them, and I think we have had considerable quantities of pot Vines from eight or ten of the most noted growers in the country. In most cases I ordered the plants about midsummer, with the special object of getting good and early ripened canes, but I never yet could get Vines that were as ripe as they should be to their extremities or without green leaves in September, and even in October, and I have always had to place them under glass to finish them. There is not so much objection to placing the plants out-of-doors, provided the roots are protected from wet and frost after the canes are quite ripe, the buds brown and hard, and the laterals also brown and ripe up to the first pinching, but before that they should be under a glass roof.

I am speaking of Vines grown from eyes the same year of course. For such plants there is no more than time for them to complete their growth and ripen their wood perfectly by August or a little later, and the sooner after that they are pruned and rested previous to starting the better. That this can be done quite well there can be no doubt. From eyes put in early in March I have had canes 7 ft. high quite ripe, nearly to the extremities of the laterals, and pruned by the beginning of September, thus giving them two or three months complete rest before forcing. These Vines were as thick as one's thumb, and some of them that were sent to an Edinburgh nurseryman were exhibited in their pruned state at the International Show in Edinburgh in September of the same year. A little later in the season a nurseryman who sells about 1000 Vines annually, would readily have taken the whole houseful at a figure much above the usual wholesale price, if we would have parted with them. The plants were never out of the house all the summer and they started early and easily into growth.

J. S. W.

Peach Trees and Galvanised Wire.—I would recommend Mr. J. Wood (p. 249) to give his galvanised wires two or three coats of paint. I cannot quite assure him that this will save his trees from being damaged, but, so far as I have tried it, I am inclined to believe it will. Another good plan is to give the matting a couple or three twists between the wire and the shoot in tying to prevent the two from coming in contact. Notwithstanding the recorded experience to the contrary, it is a fact that in many gardens galvanised wire kills the shoots of Peach trees wherever it touches them, exactly as Mr. Wood describes. Both indoors and out it does, or rather did do so, with us in almost every case where the young shoots simply touched the wires. The evil was unknown with us till we used the galvanised wire, while against our painted iron wire and wood trellises I have never noticed a damaged shoot, all other conditions being equal. I do not know whether it was to prevent the wires injuring the young shoots of the Peaches or not, but I noticed that in most of the examples of trained Peach trees at the Paris Exhibition the shoots were not tied to the galvanised wires but to straight laths placed between them and the wires, and in cases where the laths were absent the Willow withes used for tying were twisted so as to prevent contact.—J. S. W.

—Galvanised wire seems to differ in character; in some cases, if the branch only touches the wire, the latter destroys its bark, while in others no damage is done. If Mr. Wood (p. 249) will give his wires two coats of white lead and turpentine mixed pretty thickly, allowing the first coat to get thoroughly dry before applying the second, he will experience no further injury.—JAMES SMITH, *Waterdale*.

Dieu Donne Apple.—This has been on sale in Covent Garden all the season, and has met with great approval, not only on account of its beauty, but its pleasant quality. Despite a certain amount of what might be called wooliness, it is, to my taste, one of the best Apples I ever met with. On applying to Mr. Rivers for plants he told me that he had never heard of such an Apple, and that it was not mentioned in any of the French or English pomological dictionaries. I shall be glad to know whether it is in cultivation in this country, and if so where plants are to be had. In Covent Garden I was told a very remarkable but rather romantic story about the name of this Apple, which comes from the south of France, and is said to be in cultivation near Bordeaux, Bayonne, and elsewhere.—H. B.

Protecting Vine Borders.—I should not again have alluded to this subject were it not an important one. Does not Mr. Simpson see the difference between the extremes of putting on the protecting material whilst the weather is still so warm as to endanger the buds starting prematurely, and not applying it until so late that a considerable portion of the heat had been lost? Does he think that anyone having a knowledge of Grape growing would fall into the former mistake? But suppose they did. Would it have the effect of causing the Vines to break prematurely? Nothing of the kind, if the tops were kept as cool as they should be, and the treatment had been of a character to keep the old foliage on in a healthy condition for its waning time. Did any one ever know or hear of Vines thus breaking through the border being covered with protecting material? If not, raising objections to it is useless, so far as practice is concerned. Covering in borders at the proper time has been, and is still being further carried on in hundreds of places throughout the country, and the results have been found equally satisfactory, and in many cases very much more so, than when the soil is allowed to lose its summer heat and is afterwards artificially warmed.—T. BAINES.

NOTES FROM KEW.

Hardy Plants.—Of these one of the finest which we have seen for a long time is the charming new Himalayan Primula rosea, to which reference was made last week (p. 246). It is now in bloom on the rockery at Kew, and quite lights up the surroundings with its bright rosy blossoms, which are borne in considerable profusion. Some of the Kew specimens have the flower stems but little developed, forming a cushion-like mass of flowers and foliage together, but this peculiarity in no way detracts from their beauty. Another charming acquisition is the new *Chionodoxa Lucii*, which was found and introduced by Mr. Maw from Smyrna. In point of size and habit it at once reminds one of the two-leaved Squill (*Scilla bifolia*), but the flowers are fewer and much larger, being 1 in. across, with rather narrow segments of a bright sky-blue colour, gradually fading to an almost white centre. It is doing well in the open border, in company with Squills, Daffodils, and other spring flowering bulbs. In the Narcissus collection, the exquisite little Single-leaved Daffodil (*Narcissus monophyllus*) is furnished with a goodly supply of blossoms. Nothing in the way of hardy plants could well surpass the chaste beauty of this Daffodil. It is a native of Algeria, and in

order to grow it successfully it requires heat and not much moisture immediately after the flowering season is over; hence we see it here as well as at other places grown in a handlight or frame. The *Megasea* section of *Saxifraga* is now very showy, enlivening the rockeries and borders considerably. Besides the well known kinds, *S. ligulata* and *crassifolia* with their numerous forms, there is the somewhat rare *S. Stracheyi*, discovered some years ago by General Strachey, at high elevations on the Himalayas. In habit and foliage it resembles the ordinary kinds, but the panicles of blossoms are lighter in colour. *S. ornata* apparently possesses no character to distinguish it from *S. ligulata*, except in being a shade lighter in colour. The *Retusa Saxifraga* (*S. retusa*) is a neat trailing plant, much resembling *S. oppositifolia*, but differing from it in the flowers being smaller, and collected in dense terminal clusters, which, before they expand, look very much like red berries. The blossoms are of a violet purple tint. It is found plentifully in several mountainous parts of Central Europe, especially on the Maritime Alps. Remarkable more for curious structure than bright colouring is the pigmy Umbellifer *Hacquetia* (*Dondia*) *Epipactis*, another inhabitant of the Alps. Its flowers, which are yellow, are collected into a small head, surrounded by a row of yellowish bracts. Similar with regard to attractiveness is the rare Oriental *Coptis* (*C. orientalis*), a Japanese plant belonging to the Crowfoot family, with tassel-like heads of white flowers rising 3 in. high, and resembling the North American Gold Thread (*C. trifoliata*).

Greenhouse Plants.—The handsome Australian *Acacias* form the leading feature in the Temperate House, the most conspicuous being, in addition to those previously mentioned, the pointed-leaved variety of *A. longifolia* named *micronata*. This forms a large shrub with linear, pointed leaves, and literally covered with dense racemes of lemon-coloured blossoms. The whorled *Acacia* (*A. verticillata*), a kind with remarkably short-pointed, needle-like foliage, is very elegant, even in the shape of small pot specimens, and Drummond's *Acacia* (*A. Drummondii*) is now bearing long racemes of bright yellow flowers. The *Rhododendrons* continue still in beauty, and added to their number is *R. niveum*, a kind having close and rather small heads of purple flowers, but very distinct on account of the white under surface of the leaves. *R. fulgens* is in great beauty; it has deep crimson blossoms, smaller in size and more spreading than those of the others; like the foregoing, it is a native of Sikkim Himalaya. The Rose-flowered *Camellia* (*C. roseiflora*), a miniature pink-flowered species, from China, forms quite a contrast to the larger kinds on account of its size, but it is none the less showy. Its foliage is much the same as that of the ordinary kind, but in habit it is more lax. Also *abysynica*, with yellow flowers, and *A. pilicatilis*, with scarlet and green flowers, are very showy amongst succulents in the Western Octagon, but they are too cumbersome for general culture. *Hæmæthus natalensis*, a Cape bulbous plant of considerable beauty, though of rigid habit, is at present finely in flower. It is about 15 in. high, and has a stout flower stem copiously spotted with red at the base, and terminated by a large dense head of flowers with scarlet orange-tipped stamens surrounded by livid purple scales. *Imantophyllum miniatum* is a very desirable *Amaryllid*, with large orange-scarlet flowers rising from amidst deep green bold foliage. As an instance of the elasticity of its constitution, it is flowering profusely in a cool greenhouse, and also in the Palm house. *I. Aitoni*, also a native of Natal, and in the Palm house, is very inferior in point of beauty, as its flowers are much smaller and of a duller colour.

Stove Plants.—A very desirable variety of that most lovely stove plant *Plumbago rosea* is now finely in flower in the T range under the name of *superba*; the colour of its blossoms is of a much deeper shade than that of the original, from which it may be distinguished at a glance. *Geissomeria nitida* is a very showy *Acanthad* of dwarf, erect habit, with large, leathery, deep green leaves, and a terminal cluster of bright scarlet, narrow, tubular blossoms 1 in. long, with hairy stamens protruding from their mouths. Another ornamental plant of the same family is *Aphelandra pulcherrima*, a native of Columbia. It is of rather loose habit, about 2 ft. high; it has oval leaves, and the branches are terminated by heads of tubular flowers 2 in. long, of an orange-scarlet colour. *Begonia prismatocarpa* is an elegant little gem only a few inches high, and profusely studded with deep orange-coloured flowers mottled and pencilled with red; it forms a striking plant both as regards size and colour.

Orchids.—*Lælia cinnabarina*, a fine Brazilian epiphyte, is well worthy of a place in every collection on account of the deep orange colour of its blossoms, a colour seldom seen amongst Orchids. It is a very variable kind with regard to size, some forms bearing flowers fully twice the size of others. *Cologneya flaccida* is remarkable for the profusion of its long pendent racemes of creamy-white blossoms, which have a golden crest on the lip, rendering them very showy,

though their perfume is anything but agreeable. *Ornithidium coecineum*, though deep red flowered, can hardly be recommended, scarce as that colour is amongst *Orchids*, as the flowers are small and borne on short stalks, though produced plentifully enough. It inhabits one or two of the West Indian Islands. The well-known *Lycaste Skinneri* with its large blossoms of many shades of colour, varying from a deep purple to white, is now becoming attractive, and, owing to its succeeding under cool treatment and being so easily managed, it should be in every collection. *Epidendrum erectum* has for a long time assumed a gay appearance; its numerous dense clusters of dark violet flowers terminate leafy stems from 6 ft. to 10 ft. long. It is also a cool house kind and a native of New Granada.—W.

NOTES OF THE WEEK.

In the Botanic Garden, Regent's Park, a specimen of the very interesting *Winter's Bark* bears many of its singular flowers in the economic house, and a large plant of the *Giant Illicium antiquorum* bears many flowers in the conservatory. It is interesting to notice how freely the tropical *Philodendron giganteum* grows planted out in the conservatory.

Iris reticulata.—One of the few flowers that now brave the easterly breeze is this beautiful *Iris*, which is at present finely in flower in Mr. Wilson's wild garden near Weybridge.

The Spring-flowering Hellebores.—These beautiful flowers are no longer likely to be left hidden under their often ample leaves in their native hills or here and there in botanic gardens. We have lately seen a very interesting gathering from Glasnevin, and Mr. Barr and other growers are making good collections of them.

The Seeding Azaleas, crosses between *A. amena* and some of the garden hybrids, recently distributed by Mr. B. S. Williams, have this season fully proved their excellence for winter flowering by the length of time during which they remain in bloom. We saw one of these not yet sent out, named *Princess Margaret*, that had been in flower continuously from October up to the middle of March; the colour is reddish-crimson, and the flowers are good in texture, well-formed, flat, and almost circular.—P. G.

Ataccia pinnatifida.—This is now in flower in the Pine-apple Nursery. It is a most singular-looking plant, with pinnate, long-stalked foliage, and a flower spike nearly 5 ft. in height, the flowers and accompanying threads being pendent. They are chocolate-coloured, and the stem is yellowish-green and mottled. It requires a hot-house.—J. B.

American Camellias.—We understand that the new and beautiful seedling *Camellias*, belonging to Mr. C. M. Hovey, which were exhibited at the meeting of the Royal Horticultural Society on Tuesday last, and so justly appreciated as to have first-class certificates awarded them, will be offered for sale at Stevens's early in April.

Hyacinth with Fifteen Flower Spikes.—At a meeting of the Royal Botanic Society, held the other day in Regent's Park, a remarkable and very pretty *Hyacinth*, with fifteen spikes of flowers from one bulb, grown by Mr. Asplin, and a painting of the same by Miss B. Maguire, were exhibited.

"L'Art des Jardins."—We have received what is, without doubt, the most important book published for some time on landscape gardening, that of M. Ed. André, of Paris. Before we have had time to look at the book with a view to anything like a sufficient notice of it, we must, nevertheless, now announce its appearance, and say that it is extremely well produced, large, full of many practical details explaining the formation of gardens, as well as general views of design in all styles, and abundantly illustrated. Apart from these things, it will have interest for many of our readers as being the work of one who, while a thorough horticulturist of large experience and great knowledge, is also a botanist, a scholar, and one who has travelled much in many lands, and seen as much as most men of the vegetation of the world, as illustrated in gardens as well as in Nature. Such varied experience and knowledge have been brought to bear on a subject so interesting to many, and in a future number we hope to show in how far the results are instructive from the point of view of English landscape gardening.

Primula rosea.—This pretty new hardy *Primrose* is now in flower at Glasnevin, and Mr. Gumbleton writes to us as follows concerning this and other plants at present in bloom at Belgrave:—"I have now two very interesting and rare, if not new, *Primulas* in bloom in my greenhouse, raised from seed from Cashmere received and distributed by Mr. H. J. Elwes, which turn out to be *P. rosea* of Royle and a fine form, with considerably larger pipe, of *P. farinosa*, with powdered foliage and a good-sized head of bloom; these are also now in flower at Kew. Another very interesting and, I believe,

exceedingly scarce little *Irid* is also coming into flower in my greenhouse, sent to me last autumn by Mr. Whittaker, of Ferriby Brook, near Derby, as *Aristea pusilla*, but which turns out to be in reality another variety of the same family (*A. cyanea*), figured so far back as vol. xiii. of the "*Botanical Magazine*," t. 458, and also in vol. i. of Andrews' "*Botanist's Repository*," t. 10. It seems very free blooming, my small plant showing already either four or five heads of flower. I have now in great beauty, in my greenhouse, a number of lovely light-coloured hybrids of the beautiful *Primula Sieboldi*, raised by Lemoine and Dean, of Ealing; some of them are most beautiful. My large bush of *Pterotyrax hepidium*, which I thought would never bloom, has flower in nearly every shoot of the young growth. The rose-coloured *Apogoneton diatachyon*, from Machetea, is also in bloom in my pond for the first time."

New Christmas Rose.—Messrs. Barr & Sugden exhibited the other day at South Kensington a Christmas Rose named *Helleborus orientalis*, var. Dr. Moore, a seedling raised at Glasnevin. Its flowers which are rose tinted, are very beautiful. Dr. Moore describes it as a very ornamental border plant, and being of the taller kind of the later-flowering Christmas Rose, it would make a good pot plant for the decoration of cool houses in winter. It is more ornamental than any of the Berlin seedlings which we have flowered in this country.

SOCIETIES AND EXHIBITIONS:

ROYAL HORTICULTURAL SOCIETY.

MARCH 25.

NOTWITHSTANDING a heavy snowfall, which lasted all day, there was on this occasion an excellent show, which was visited in the course of the morning by H. M. the King of the Belgians. The chief attractions were some fine groups of plants from Mr. Wills, a bank of *Hyacinths* from Messrs. Veitch & Sons, and *Cyclamens* from the leading growers.

First-class Certificates.—These were awarded as follows:—

Hyacinth King of the Reds (Veitch & Sons).—A variety with short, compact flower spikes, thickly beset with double dark red blossoms.

Hyacinth Leviathan (Veitch & Sons).—A sort having noble spikes of blossoms, which individually are unusually large, well formed, and of a lively flesh colour.

Camellia Mrs. Hovey (Hovey & Co.).—A kind with flowers of medium size, exquisitely formed, and of a delicate pink colour.

Camellia C. M. Hovey (Hovey & Co.).—A red-flowered kind, excellent in form, and well worth attention.

Azalea Duke of Connaught (Williams).—A dwarf-habited kind, having purplish-crimson, hose-in-hose blossoms.

Galanthus nivalis Melvillei (D. Melville).—A robust growing kind with large, well-shaped flowers of snowy whiteness.

Hyacinth The Sultan (Veitch & Sons).—A kind with very stout symmetrical trusses of blackish-blue flowers.

Hyacinth Duchess of Connaught (Veitch & Sons).—A wonderfully showy kind, with bold trusses of pale blue flowers.

Hyacinth Salmon King (Veitch & Sons).—A valuable variety, with salmon-coloured blossoms.

Rose Madame Alexander Bernaix (Turner).—A hybrid Tea Rose, having large, finely-shaped, globular blossoms of a bright pink colour; evidently a good addition to the class of Roses to which it belongs.

Cyclamen Queen of the Belgians (H. B. Smith).—A dwarf-habited kind with pure white, broad-petalled flowers; excellent for market purposes.

Primula rosea (T. S. Ware).—This charming addition to hardy *Primroses* was fully described in *THE GARDEN* last week [p. 246].

Amaryllis Mrs. Baker (Veitch & Sons).—One of the best of *Amaryllises*; on one spike it bore four fully-developed blossoms, with broad, round, recurved petals of a rich crimson colour.

Medals.—Mr. John Wills was awarded a gold medal for a collection of *Orchids* and other plants, and Mr. Bull received a similar award for a collection of new and rare plants. For a group of flowering and fine-foliated plants, Mr. B. S. Williams received a silver-gilt Banksian medal, as did also Messrs. Osborn & Co. for a miscellaneous collection of plants, and Messrs. Paul & Sons, Cheshunt, for a group of pot Roses. Mr. R. Dean had a silver Banksian for a collection of plants of *Primula denticulata*, and similar awards were made to Messrs. Paul & Sons, Waltham Cross, for cut blooms of *Camellias*; to Messrs Charles Lee & Sons, Hammer-smith, for a group of miscellaneous plants; and to Mr. Aldous, South Kensington, for dinner-table decorations. To Messrs. Veitch & Sons, Chelsea, was awarded a gold medal for a collection of *Hyacinths*, and Messrs. Osborn & Sons had a silver gilt Banksian for *Hyacinths*. Mr.

Moorman, gardener to Messrs. Christy, Kingston, was awarded a gold medal for Hyacinths, Tulips, &c.

Groups of Plants.—Mr. John Wills, exhibited a group of plants such as are rarely seen this season. Amongst them we remarked well-grown examples of *Paulinia thalictrifolia*, *Rodeja macrophylla*, bearing large trusses of snowy-white blossoms, *Bertolonias*, *Droseras* under glass cases, fine-leaved Palms, Ferns, New *Dracenas*, *Yuccas*, well-flowered *Gloxinias*, *Amaryllises*, *Anthuriums*, fine-leaved *Crotons*, and *Caladiums*. The same exhibitor also showed an attractive group of finely-flowered Indian Azaleas, set in an irregular bed of Maiden-hair Ferns, Grasses, *Cyclamens*, blue *Cinerarias*, &c. In the centre of the two collections described was a tasteful arrangement suitable for a sideboard, and back-ground of which consisted of Ferns, finely flowered examples of *Dendrobium Wardianum* D. noble, and *Odontoglossum Alexandria*, with long, graceful flower spikes; mixed with these were dwarf Palms and Lady's-tippers. The bed was composed of the close-growing *Selaginella apoda*, in which were plunged groups of Tea Rose blooms, fine spikes of flowers of *Dendrobium Wardianum*, and flowering plants of *Gloxinias*. Mr. Wills also showed the grand *Sèvres* vase, won at the Versailles Exhibition, also medals from the Paris Exhibition. Mr. William Bull sent a large and attractive group of new and rare plants, amongst which were finely-flowered *Orchids*, *Anthuriums*, the double white *Epacris* (*E. oncosmeflora* fl.-pl. nivalis), and fine-leaved *Cycads*. Amongst *Orchids* was a group of well-flowered plants of *Odontoglossum cirrhosum*, also well-flowered examples of the pretty *Odontoglossum Phalaenopsis*, the scarlet *Ada aurantiaca*, *Oncidium sarcoodes*, *Masdevallians*, small plants of *Lycaste Skinneri* *cerina* (bearing ten magnificent ivory-white flowers), the chocolate and green *Odontoglossum triumphans*, *Dendrobium Wardianum*, and fine *Cattleyas*. Mr. B. S. Williams furnished a group of plants, consisting of fine-leaved *Dracenas*, *Amaryllises*, *Sarracenia Drummondii* in bloom, and other insectivorous plants; also *Zebrina Maria Regine* and *Cyclamens*. Mr. Roberts, Gunnersbury Park, showed a charming group of *Orchids*, *Amaryllises*, and Ferns. Among the *Orchids* was a plant of *Odontoglossum Andersonianum* with two spikes, each bearing nearly forty blossoms; also well-flowered examples of *Phalaenopsis Schilleriana*, and fine varieties of *Odontoglossum Alexandria*. Mr. Aldous, South Kensington, showed a good group of flowering and fine-foliated plants, but too much crowded to be seen to advantage. Messrs. Paul & Son, Chesham, contributed a group of Roses excellent for the season. Among others were *La France*, John Stuart Mill, Captain Christy, Duke of Edinburgh, Madame Lacharme, Jean Pernet, Charles Lefebvre, and Princess Mary of Cambridge. Messrs. Osborn & Sons, Fulham, and Messrs. Lee & Sons, Hammersmith, also showed attractive groups of flowering and fine-foliated plants, including *Limnophyllums*, *Rhododendrons*, *Azaleas*, *Clematises*, *Cyclamens*, and *Dentizias*.

Hyacinths.—Of these Messrs. Veitch & Son exhibited a collection remarkable alike for quantity and quality, upwards of 300 plants, perfect as regards culture, being staged. Their spikes were strong and symmetrical, and the individual flowers possessed of great substance. Over eighty new sorts were included in this collection. Messrs. Osborn & Sons, Fulham, also furnished a collection of well-grown Hyacinths, and a good group likewise came from Messrs. Carter & Co.; these were backed up by finely-flowered plants of *Dicentra spectabilis*, and edged with clumps of Lily of the Valley. Mr. Moorman, gardener to the Misses Christy, Coombe Wood, Kingston, showed a well-grown collection of Tulips, Hyacinths, and Crocuses. Messrs. Cubush & Sons, Highgate, also sent a well-grown collection of Tulips and Hyacinths, and fine panfuls of Lily of the Valley.

Cyclamens.—Of these hundreds of finely-grown plants were shown by Mr. Edmonds, of Hayes, and Mr. B. Smith, Ealing. The latter had also a large group of *Cyclamens* with pure white flowers, many of them deliciously scented.

Hardy Flowers.—Mr. Dean, of Ealing, had an interesting bank of hardy flowers, consisting of finely-grown, well-flowered examples of *Primula denticulata* and its varieties; various *Primroses*; Siberian *Squills*; *Vicia Profusum*, a pure white, fine Sited kind excellent for spring gardening; *Polyanthuses* and similar plants; all of which served to show how attractive a cool greenhouse may be made in winter by means of such hardy plants. Mr. Parker, Tooting, also exhibited a collection of hardy plants, consisting of finely-flowered examples of *Megaseas*, *Hepatica triloba* *coriacea*, and cut blossoms of *Aponogon distachyon*; also flowering plants of the gold-leaved *Aubretia deltoidea*; the sweet-scented *Iris denticulata*, so well adapted to pot culture; the earliest of the *Daffodils*. *Narcissus vinor*, *Bulbocornea*, a pure white, fine Sited kind. Messrs. Barker & Saenger sent a plant of *Heliborus orientalis*, var. Dr. Moore, fully attested elsewhere. Mr. Ware, of Tottenham, showed various hardy *Primulas*, consisting of *P. denticulata*, an interesting variety named *P. d. purpurea*; a variety of *P. denticulata* from Cashmere having compact heads of purple blossoms and gold-powdered leaves; also the pretty dwarf *Primula rosea*, a new species now in flower for the first time simultaneously in various collections.

Floral Decorations.—Messrs. Green & Co., Victoria Street, sent two very attractive arrangements composed chiefly of *Camellias*, *Orchids*, *Rose buds*, *Stephanotis*, and *Eucharis*. A very attractive dinner-table arrangement was shown by Mr. Aldous. It consisted of three light and elegant gold-coloured stands, named the *Isabella* stand, with trumpet glasses filled lightly with Lily of the Valley, white Lilacs, *Orchids*, *Spiraeas*, and double white *Primulas*. There were also several dishes of fruit and some coat bouquets, the whole making a charming table.

Miscellaneous Subjects.—Messrs. Wm. Paul & Sons exhibited twenty boxes of cut blossoms of *Camellias*, which were greatly admired on

account of their variety of colour, size, and substance. Mr. Parr, of Harrow Weald Park, showed new Abutions of a meritorious description. Messrs. Veitch & Sons showed plants of a new *Dracena*, from the South Sea Islands, named D. Princess Marguerite. Mr. Green, gardener to Sir G. Macleay, contributed cut blossoms of *Prostranthera lasianthus* and *Salvia elegans*. Mr. Cannell showed some remarkably fine blossoms of zonal *Pelargoniums* on a bed of the dwarf green *Nertera depressa*. Messrs. Veitch & Sons showed a finely-grown specimen of *Rhododendron Veitchii*, a greenhouse species from the Khasia Hills, bearing large, showy, white flowers, with frimbriated edges. Mr. B. Williams showed *Azalea Duke of Connaught*, a dwarf kind, with small, brilliant rose-crimson flowers, and excellent for forcing. Mr. Charles Turner, Slough, exhibited a basketful of the Tree *Carnation A. Alegatieri*, which is considered to be one of the finest scarlet-flowered kinds for winter blooming. Messrs. Cubush & Son, Highgate, showed stands of *Camellias*, among which were *Etimia*, scarlet; *Queen of Beauties*, peach colour; *Mathottiana*, crimson; *Cap of Beauty*, white; the striped *Lavina Margi*, its rose-coloured variety, and other fine kinds. Mr. Parker, Tooting, sent a flowering plant of *Dendrobium superbum giganteum*, having large and attractive purple and violet blossoms. Mr. Stevens, The Gardens, Trentham, showed a fine variety of *Odontoglossum Andersonianum*, one spike of which bore eighteen large, finely-spotted blossoms.

Fruit.—Mr. L. Killick, Langley, Maidstone, showed a collection of Apples remarkable for their good quality, all the specimens being large, sound, and highly-coloured. Among the best were *Sunmer Quoining*, *Bedfordshire Foundling*, *Beauty of Kent*, *Winter Nonsuch*, *Count Penda Plat*, *King of the Pippins*, *Northern Greening*, and *Tower of Glamis*.

ROYAL BOTANIC SOCIETY.

MARCH 26.

THE plants which formed the chief features of this show were those shown at South Kensington on the previous day, and of which mention has just been made.

First-class Certificates were awarded to Messrs. Veitch & Sons for *Amaryllis* Mrs. Baker, *Epidendrum Wallisi*, *Davallia Mariesi*, *Asplenium Neo-caledonicum*, and to the following Hyacinths, viz., Duke of Connaught, single dark blue; Royal Blue, blue, white centre; Duchess of Connaught, single light blue; Duke of Norfolk, semi-double, dark blue; King of Reals, fine rose-red; Salmon King, flesh colour; Lord Derby single, red striped; and MacMahon, single yellow.

Mr. James, Isleworth, received certificates for *Cinerarias* Master Harold, rosy crimson, shaded purple, with a white disc; Mrs. Bland, white, edged with violet; and Earl Beaconsfield, dark maroon-purple.

Mr. H. B. Smith, Ealing Dean Nursery, had a certificate for *Cyclamen Duke of Connaught*.

Mr. Little, Hillingdon, received a certificate for *Cyclamen The Gem*, a charming kind with broad, round, white petals edged with rose. Certificates were likewise awarded to Mr. Williams, of Holloway, for *Pandanophyllum humile*, *Croton albicans*, *C. Williamsi*, *Calyptronon Swartzii*, and *Gleichenia dicarpa longipinnata*.

Also to Mr. Bull, of Chelsea, for *Davidsonian pruriens*, *Staphylea colchica*, *Epacris oncosmeflora*, *Adiantum bellum*, *Lactaria aristata variegata*, and *Macrozamia McKenziei*.

Messrs. Low, of Clapton, received certificates for *Cymbidium Lowii*, and Mr. Boller, South Kensington, for *Agave marmorata*, and *A. Shawii*.

Messrs. Veitch and Sons, Chelsea, showed a fine bank of Hyacinths, among which were eighty new kinds, the best of which were—*Cardinal Wiseman*, pink and white; *Duke of Connaught*, blackish purple; *Troca-dero*, rosy pink; *King of the Reds*, rosy red; *Pottgieter*, lavender; *Leviathan*, flesh colour; and *Duchess of Connaught*, light blue. Amongst the older kinds were: *Whites*—*La Grandesse*, *Queen of the Netherlands*, *Mont Blanc*, *Madame Van de Hoop*. *Reds*—*Prince Albert Victor*, *Vuurbaak*, *Van Schiller*, *Princess Louise*. *Dark Blues*—*Baroness Van Tuijl*, *King of the Blues*. *General*—*Lividula*, *Marie*. *Light Blues*—*Lothair*, *Lord Derby*, *John Bright*, *Czar Peter*.

Messrs. Osborn, Cubush, and Carter & Co., had also fine displays of Hyacinths and other plants. Mr. George Paul, who was the only exhibitor of Roses, had a large group, in which were fine blossoms of *Comtesse de Serenye*, *John Keynes*, *La France*, *Annie Alexief*, *John Bright*, *Captain Christy*, and *Madame Lacharme*.

Mr. Williams showed a good collection of plants, conspicuous amongst which were *Zebrina Maria Regine* in flower, *Rhododendron Davidsonii*, new hybrid *Blues* (obtained by crossing *A. amona* with large-flowered kinds), giant *Cyclamens*, forms of *Primula denticulata*, *Cycads*, Palms, fine-leaved *Dracenas*, *Sarracenia flava*, *Gleichenias*, *Casuarina ericoides*, and *Adiantum Farleyense*.

Mr. Bull, of Chelsea, had a fine display of *Orchids* and fine-leaved plants.

Azaleas were not so good as we have seen them in former years at spring shows. The best of the dozen came from Mr. Ratty, gardener to H. Thorndon, Esq., of Sandham, who had well-flowered examples of the purple *Reine des Roses*, *Duc de Nassau*, the robust scarlet-striped *Madame Ambroise Verschaffel*, and the semi-double *Constant Van Keersbloom*. Mr. James, Redles, Isleworth, had also well-grown plants, among which were *Criterion*, *Iveryana*, and the brilliant kind called *La Superb*.

Messrs. Cubush & Son showed basketfuls of plants consisting of *Epacris*, which made a good display. Among the best kinds were *odorata alba*, white magnifica, pink; *Waltoni*, flesh colour; *Newton*,

white; *hyacinthiflora* candidissima, white; Fireball, red; Model, rosy-pink; a very dwarf and pretty white kind named The Bride, and a variety named Lady Alice Peel, rose, tipped with white.

Mr. Douglas, Loxford Hall, Ilford, exhibited some fine plants of *Narcissi*, amongst which the best were *gloriosi*, Grand Monarque, Queen of the Netherlands, and Grand Soleil d'Or. The same exhibitor had also some plants of *Deutzia gracilis*, 8 ft. high and as much through, complete masses of snowy-white blossoms. Mr. Douglas likewise showed the best Tulips consisting of Vermilion Brilliant, Proserpine, and Keizer Kroon.

Mr. Boller, South Kensington, sent a large collection of miniature Cacti.

Mrs. Messelbrook, St. John's Wood, exhibited flowering plants of the richly-coloured *Amaryllis formisiana*.

A list of prizes awarded on this occasion will be found in our advertising columns.

LONDON INTERNATIONAL HORTICULTURAL EXHIBITION FOR 1880.

It is a source of deep regret to me that my colleagues so quietly shelved the idea of holding the above show next year at a meeting which was held on the 18th. I think when we had such an excellent opportunity of carrying out the arrangements for the exhibition, backed as we were by Her Majesty's Commissioners for 1851, who would, I feel sure, have lent us their willing aid if we had asked them, it should have been done, and I feel sure its failure will be deeply regretted by horticulturists generally. The fact is simply this, a few of us have arrogated to ourselves the position of thinking for the general body of horticulturists in the country, instead of, as I have urged the committee time after time, calling a general meeting by advertisement. This is what ought to have been done months ago, when, I feel sure, horticulturists, as a body, would not have considered any crisis at the present time an obstacle to carrying out the show successfully fourteen months hence. It is not reasonable to suppose that Her Majesty's Commissioners would ever listen to any overtures for the site at any future time unless they came from a more spirited body of men than those who have brought the present negotiations to such a miserable failure.

I still hope that Her Majesty's Commissioners will themselves carry out the arrangements for this most important exhibition, and if they do not feel disposed to do so on their own responsibility, there are plenty of people (not strictly horticulturists) who would speedily guarantee £15,000 or £20,000; and if there be no other means of attaining this end, and Her Majesty's Commissioners will let the gardens, arcades, and Albert Hall for the purposes of an international show in 1880; I have no doubt I can find gentlemen willing enough to furnish the required amount for the purpose. I, therefore, appeal to the great body of horticulturists to support me in this undertaking, in order to prove to the few that the spirit of emulation is still potent. I trust that a large meeting will shortly be held, and that the general and predominant feeling will be to push the proposed exhibition to a successful issue with might and energy. What can be more conducive to the welfare of millions of our fellow countrymen than the cultivation of their minds, brought about under the influence of Horticultural teaching? Take the labourer, for instance; how much pleasure does he not derive from the cultivation of his little cottage or allotment garden after his day's toil is over in the fields? Having refreshed himself with his humble meal, he goes forth into his garden, and occupies the remaining daylight in what proves to him a source of pleasant recreation, beneficial alike to himself and his family, instead of spending his hours in idleness. If there be in his neighbourhood a village horticultural society, his energies are stimulated to their fullest extent by the hope of gaining some of the prizes to be competed for. I therefore maintain that the example set by a great International Horticultural Show held in London would be productive of immense benefit to the whole of the country by infusing a spirit of emulation into the breast of every cottager in the country. I cannot help thinking that if the exhibition in question was carried out, that Her Majesty's Commissioners of the Exhibition of 1851 would be conferring a large amount of benefit on countless thousands of Her Majesty's subjects, and be fulfilling the ideas intended when they were appointed the guardians of the money entrusted to their care, and which was derived from millions of the humble workers in the great hive of industry in Her Majesty's dominions, and I cannot conceive any greater advantage Her Majesty's Commissioners could confer, nor anything likely to be more conducive to the general good of the country than their encouraging an exhibition of this kind.

JOHN WILLS.

16, Onslow Crescent.

Scottish Seed and Nursery Trade Association.—At the annual general meeting of this Association, as will be seen by an advertisement in another column, attention was directed to the importance of arbitration in all cases of dispute between buyers and sellers of seeds and plants, thus saving the expense, and too often vexations, as well as unsatisfactory litigation. For carrying out this resolution, it was resolved to place the services of the committee at the disposal of all disputants upon the payment of one guinea towards the funds of the Association, besides all expenses incurred in connection with each case brought forward. All further information on this most important arrangement may be had upon application to the secretary. In connection with what may

be considered the primary object of the Association, viz., the prevention and exposure of attempts to vend adulterated seeds, it was agreed to offer to seedsmen and nurserymen's assistants a prize of £5 for an essay on the best means of discovering the various forms of adulteration and admitting water seeds, stating particulars of all foreign substances found in any questionable samples offered for sale. Competitors for this prize must lodge their essays with Mr. David Hunter, secretary of the Association, on or before November 1 next, for adjudication of the judges to be appointed by the committee. All parties desiring to join the Association may remit the annual subscription of one guinea to the secretary.

ANSWERS TO CORRESPONDENTS.

Lilium auratum.—How am I to obtain blooming plants of this in the shortest time from seed?—INQUIRER. [I should sow in a deep seed pan, place it in a greenhouse and leave it for three years, then pot the bulbs; when sown out of doors, we have found that the bulbs do not flower for six or seven years.—G. F. Wilson, *Heatherbank, Weybridge.*]

Has Lead Wire any Injurious Effect on Roses?—Both last year and this I observed, in pruning my Roses, that the branch to which the label was attached was, in many cases, dead; the labels are zinc, tied loosely round the branch with lead wire. In some instances the branch was quite healthy.—B. F. T., *Belfast*. [I have not observed any especially bad effect from the use of lead wire. It is best to attach the label to the stem of the tree (taking care to loosen the ties each year, as a small branch is almost sure to be cut through by the wind-waving of the wire and label).—GEO. PAUL.]

Strawberry House.—I am about to have a Strawberry house erected, but before doing so, I should be glad of some information on the subject.—C. J. H. [For Strawberry forcing there is nothing better than an ordinary forcing pit, with a stage in the form of a stair. By this arrangement, every plant is near the light and easy of access by simply drawing off the lights. The heating power should be sufficient to ensure a minimum temperature of 50° on the coldest nights.—W. W. H.]

Books.—*W. F. G.*—Parnell's "Grasses of Britain" might, perhaps, be obtained of some second-hand bookseller. The Lawson Company publish some works on Grasses which may answer your purpose.

Stephanotis floribunda.—*A. A. Thorn.*—It is not unusual for this to bear seed pods.

Castor-Oil Plant.—*R. P.*—There is a short article on the cultivation of the above, with other statistics, in "Tropical Agriculture," by P. L. Simmonds; published by Spon, Charing Cross.—J. W.

Names of Plants.—*S. L. B.*—It is very difficult to name *Hyciaths* from single bells, many of them being very much alike. We think the one you send is *Lord Wellington*, but we are by no means sure. *Hyciaths* might be propagated successfully in many parts of England, a principal requirement being a deep sandy soil; but the process is tedious, and would not pay commercially, unless carried out on a very large scale.—*W. P. E. D.*—1, *Oncidium cryptocarpis*; rather a rare kind. 2, *Cypripedium Schlimgii*. *G. T.*—We cannot undertake the naming of *Camellias*, which should be sent to some specialist; No. 1 seems to be *anemoneflora*.

Fruit Rooms.—A hint or two about fitting up a fruit room would be of service to me. What I have got to work on is a two-stall stable long disused, and I thought of leaving the ramp, and carrying narrow shelves (of splints with spaces between them) round each stall, so as to avoid having any quantity of fruit out of sight. I should further darken the windows with shutters. Beyond this I am ignorant.—*TYRO*. [Your stable will make a very good fruit room if the aspect is north or east; if open to the south or west, the air of the room would be too dry and, though, to a certain extent, this could be neutralised by provision being made for keeping all ventilators closely shut, such a condition is not desirable, as a slight circulation of air is, at all times and in all weathers, short of actual frost, necessary; of course, a damp situation would be equally bad as south or west, only this is easily remedied by means of drains. The proposed shutters would be needed; and, occasionally, when necessary to dry the room, the windows might be opened; but a couple of ventilators in the roof would be much preferable. Your plan for shelving cannot be improved, but if you can add drawers for some of the latest kinds of Apples and Pears, they would keep longer without shrivelling. Understand, these are only for the longest keepers; the early and mid-season fruits would rot in such drawers.—*W. H.*]

Neglected Orchids.—I am anxious to inquire if much is known of *Vanda alpina*. I have a plant in a 5-in. pot with forty-nine expanded flowers; as it is a very small flowering variety, perhaps it is dismissed by most growers as insignificant. I have rather a fancy for many of the rejected ones; I can hardly imagine, however, as this plant in question is a *Vanda* at all; the deep recess or bag behind the lip reminding one more of a *Saccolabium*. Another plant seldom seen is *Meiracium* a plant, with lovely, Sophronitis-like, violet blossoms, which I should have thought would have won for it a place amongst the upper ten.—*R.*

The Southampton Horticultural Society.—This Society, which in future is to be called the Royal Southampton Horticultural Society, offers, we observe, prizes for the coming year amounting in the aggregate to £350.

HIS MAJESTY the King of the Belgians honoured Mr. Wills' establishment with a visit on Tuesday last, after inspecting the Royal Horticultural Society's Show at South Kensington.

"This is an art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

INDOOR FRUIT GROWING FOR MARKET.

PEACHES AND NECTARINES.—The chief supply of early Peaches and Nectarines comes from France and Spain. These are succeeded by fruit from the Channel Islands; and mid-season and late Peaches and Nectarines are supplied to a large extent from the south and other parts of England, chiefly from private sources. There are, however, several Peach growers for market near London. In a small place at Barnet both Peaches and Nectarines are well grown, though in a somewhat primitive manner. The houses in which they are grown are of the half-span-roofed kind with a pathway through the centre. In the earliest house the trees grow in an inside border of very limited dimensions, but they, nevertheless, appear to thrive remarkably well, and yield enormous crops of fruit. The trees in the other houses occupy an outside border. During the autumn, after the fruit has been gathered, the lights are removed from the roof, and the trees are exposed to the full influence of the weather, which has the effect of cleaning and hardening the wood, as well as allowing the border to become thoroughly soaked with rain-water. The first house is started early in January, and the Peaches are usually ripe early in June; the second house is started a month or six weeks later, to succeed the first, and the trees in the third house are allowed to come on without much forcing, and to ripen their fruit just before the early outdoor Peaches come in. In the second early Peach house I noticed a tree that covered 300 square ft. of trellis, then bearing over thirty-five dozen fruit. Other trees in the same house, though not quite so large, were proportionately fruitful. In such old trees as these are I never remember seeing so much young and fruitful wood. Indeed, it is surprising how they have borne such heavy crops for years in succession, and still retain their health and vigour. The borders, both inside and outside, are covered with rotten manure when the trees are started into growth, and this not only nourishes the roots, but also keeps the soil moist, thus obviating the necessity of frequent waterings.

A good plan seldom adopted in the growth of indoor Peaches and Nectarines is well carried out in a market garden not far from the one just alluded to. The proprietor calls it the ridge-and-furrow system, but it is, in fact, the cordon plan, which is largely practised in France. The trees, twenty-five in number, are planted, 3 ft. apart, on the south side of a half-span-roofed house; their main stems are trained upwards like Vines $2\frac{1}{2}$ ft. from the glass; each stem is furnished on both sides with healthy spurs, from which are emitted from five to eight shoots. When pruning, three or four of the best-ripened fruit-bearing growths are selected, and the rest are cut away, leaving in all cases a few eyes to furnish young shoots during the ensuing summer for supplying the next year's crop. The shoots which are left for fruit-bearing are not trained out horizontally, as is generally done in the case of Vines; on the contrary, they are trained towards the glass, and thus form, as it were, a ridge and furrow. The kinds of Peaches grown are Royal George, Noblesse, Grosse Mignonne, Late Admirable, Barrington, and other sorts, which

naturally succeed each other, thereby prolonging the season during which fruit can be had in good condition. The Nectarines consist of such kinds as *Violette Hâtive*, *Balgowan*, and other popular sorts, all of which succeed on this system remarkably well. From this house in one year were gathered nearly 1500 large and excellent fruits, which found a ready sale at good prices in the market. The house is started in January, and the trees are brought on gradually; gathering commences towards the end of July, and an abundant supply of fruit is obtained until the beginning of August. The trees had only been planted three years, and so satisfactory had been the results, that it was proposed to do away with trees trained in other ways and replace them with cordons—for in seasons when complaints were being made about Peaches falling off, these trees carried a crop that would have surprised many of our best growers, three, four, and five large fruits being observable on single shoots. In order to still further utilise space, it was proposed to lower the main stems of the trees and train the shoots in a more upright direction towards the glass. The trees had only covered one side of the roof, but it was intended to train them down the other side, which, when I saw them, for the time being, was covered with Tomatoes, on which there was a heavy crop—a result attained by constant stopping of the young growths and by the removal of superfluous foliage, so as to throw the vigour of the plants into the fruit. Peach trees, after being cleared of fruit, are well watered and the leaves kept well syringed, all air and sunshine possible being admitted in order to thoroughly mature the wood and buds. As soon as the leaves have fallen, all shoots which have borne fruit are cut back, and the young growths which have been selected for bearing next year are laid in their places.

Several very large Peach trees may be found in Mr. Kay's garden at Finchley. They are of great age, but under the culture to which they are subjected, they yearly bear heavy crops. The chief conditions are—keeping the wood well thinned by timely disbudding and pruning, thoroughly ripening that which remains, and during the time the trees are in fruit supplying their roots with abundance of water. The fruit is ripe in July and August, and better fruit than that grown here is seldom seen in Covent Garden. Even in seasons when there is elsewhere a comparative scarcity of Peaches these old trees carry heavy crops. Too rapid forcing, insufficient ventilation, and dryness at the roots are the chief causes why people lose their crops of Peaches and Nectarines. In order to convert all available space to profitable account during the time when Peach trees are at rest, plants, such as *Solanums*, *Cytisus*, *Fuchsias*, and *Pelargoniums*, are grown in the houses. Cuttings of these are struck during the summer, potted, and placed out-of-doors or in cold frames until unfavourable weather sets in, when they are removed to the house, in which are moveable stair-like stages provided for them near the glass.

Mr. Yeldham, of Fulham, has also two houses devoted to Peach trees, which are trained on wire trellises under the roof. *Barrington*, *Violette Hâtive*, and *Royal George* are the kinds grown, the latter succeeding remarkably well here, ripe fruit having frequently been gathered from the trees weighing from 8 oz. to 10 oz. each. Standard Peach trees, to which allusion has already been made, are also successfully grown under glass.

Peaches and Nectarines out-of-doors are not very largely cultivated near London, and where they are the trees are, of course, nailed to walls. There is no reason, however, why Peaches and Nectarines should not in favourable

localities be planted and grown as standards. We should not, of course, expect them to produce fruit of the best quality, but in favourable seasons good crops of second and third-rate fruit might be looked for with tolerable certainty. In a small garden at Cheshunt, I saw a standard Peach tree from 15 ft. to 20 ft. high, and as much through, and at the time of my visit its branches were literally loaded with fair-sized, well-coloured fruit; the proprietor informed me that this tree had that year yielded at least 1000 sound and usable Peaches, and their flavour, though, of course, not equal to that of those grown on walls, was refreshing and good. This tree had been planted about eight years, having been previously grown in a pot. After planting, no attention had been paid to it beyond now and then, when it was found necessary, thinning out a few over-crowded or unfruitful branches. In previous years I was informed that the fruits produced were much finer than in the season when I saw it, owing to their having been thinned out a little whilst in a green state. The variety was the Early York, but other kinds of a less hardy, but much choicer, character, were also growing in the same garden in the form of dwarf pyramids, and were all liberally bearing large, and in every way excellent, crops.

PINE-APPLES.—There are now only about two places near London where Pine-apples are grown for market, and in these the fruit is ripened late in summer, when foreign Pines are not so abundant. Pine-apples formerly occupied a prominent position in Mr. Wilmot's establishment at Isleworth, but now only a few hundreds are fruited there annually, and these chiefly for supplying private customers. To grow Pine-apples for market does not pay—not because they cannot be produced as cheaply now as ever they have been, but the profits required by London retail fruiterers are so great, that consumers will not buy English-grown Pines so long as they can get imported ones at a much lower price. During the summer months there is a fair demand for home-grown Queens, which realise at that season high prices; but it is just possible that foreign growers will in time make provision for furnishing Pines at that season. Queens and Black Jamaicas are the only kinds now grown in market gardens, these being of much finer flavour than any others which ripen during summer,—the time when the bulk of English market Pines are ready for use. Where Pines are still cultivated for market, they are grown in pits plunged in leaves and rough manure, none of the more complicated methods of supplying bottom-heat by means of hot-water having found their way into market Pineries. Hot-water pipes are, however, used to supply top-heat, but the whole system is what most people would call a rough-and-ready way of growing Pines. Nevertheless, excellent fruit has been and is still produced under such conditions.

C. W. S.

Shortia galacifolia.—This highly interesting and rarest of North American plants is now in blossom in one of the greenhouses in the Botanic Garden, Cambridge, Mass., where it is an object of great attraction. It is a sweet little plant, not showy by any means, but a welcome garden Alpine. It is about 4 in. high, with Galax-like leaves, both as regards form and brownly colour, and pure white bell-flowers, borne singly on stems 3 in. high. In 1778 Michaux discovered a *Pyrola*-like plant in the mountains of North Carolina, and secured the specimen, which was in fruit, but not in flower for his herbarium. Beyond that specimen, not another vestige of the plant, dead or alive, was known to exist till last year (1878), when it was re-discovered growing on a hillside in North Carolina, and specimens were then sent to the garden here. Long before its re-discovery it was earnestly but unsuccessfully hunted for by Dr. Asa Gray and others; and even now so much importance is attached to the long-sought mountaineer, that

a special company of botanists from here are to visit it in its native wilds as soon as its flowers open in the spring. It was named by Dr. Gray in compliment to Dr. Short, an eminent botanist of Kentucky. A nearly allied species, namely, *Shortia uniflora* (Schizocodon uniflora) was discovered not long ago in Japan.—WILLIAM FALCONER, in "Country Gentleman."

THE FLOWER GARDEN.

PLANTS FOR THE SUB-TROPICAL GARDEN.

Nothing forms a more distinctive feature in the embellishment of gardens, or helps to break up the uniformly flat surfaces of beds so much as fine-foliaged plants, one or other of the most striking of which placed in the centre of a circle gives it a finish quite unattainable in any other way. Not only are they very effective used in this manner, but they are equally so for grouping in masses or standing as isolated specimens on lawns, for the latter of which purposes some of them are specially adapted. One of the most serviceable for this kind of work is *Chamerops Fortunei*, a Palm that is not only exceedingly ornamental after it has attained a fair size, but one which has the additional merit of being quite hardy in localities that are in any way favoured. Even in the most northern districts of England it will stand any ordinary winter if slightly protected by putting a few leaves or dry litter around the stem and collar, for, with these vital parts a little sheltered, the foliage may with safety be left to take care of itself. To test its enduring powers I have had one left in a very exposed situation without the slightest cover, and although, as is well known, the winter has been one of unusual severity, the plant at the present moment looks as fresh and well as it did in the autumn. The way in which this fine-looking Palm is best managed is to turn it out early in the spring, after being properly prepared for the change, as then it has time to make its growth and become firmly established before bad weather sets in. To give it a good start, which is half the battle, a large hole should be dug previous to planting, and if the natural soil be bad, the space should be filled with sandy loam and leaf mould, but in all cases when the latter is used, it is a very important matter that it be thoroughly decomposed and entirely free from sticks or anything of that kind likely to engender fungus, a parasite which, when it attacks the roots of plants, soon throws them out of health and frequently destroys them altogether. There are many other Palms that are valuable for plunging out in conspicuous places during the summer, the most noticeable of which are *Areca sapida*, *A. Baueri*, *Latania borbonica*, *Phoenix reclinata*, *Chamerops australis*, and *Phoenix dactylifera*, but none of these will bear sharp frost, and should, therefore, be moved under cover by the end of October.

Another noble-looking plant for planting as a specimen is *Aralia Sieboldi*, which has leaves considerably larger than those of the Fig, and, being of a pleasing shade of green, and singularly bright and polished, they have a very striking appearance, which is heightened in the spring when the plant comes into flower, and begins to bear seed. Seeds, obtained and sown now in heat will make very useful-sized plants by the autumn, that will be of great service for the embellishment of rooms, halls, corridors, &c., as, owing to the thick, leathery texture of its magnificent foliage, this *Aralia* will stand in places where there is not much light better than any other plant with which I am acquainted. There is a variegated variety which is even more ornamental, owing to the leaves being margined with a rich, creamy-white band, but this colouring appears to have made it more tender than the normal form, as it does not bear the cold so well. It is, however, a most valuable plant for decorative purposes indoors, especially during the winter, when plants of an ornamental character are not over plentiful. Unfortunately, it cannot be raised from seed, and is not very free in affording cuttings, which makes it scarce and dear as yet, but it is one of those good plants that are quite worth the first outlay, as it is sure to give satisfaction. For forming bold masses in the sub-tropical garden, *A. papyrifera* should not be forgotten, as, grown in deep, rich soil, it is a remarkably stately-looking object that will endure a good deal of cold and wind without suffering or getting its leaves torn and injured in the way so common with many others that

attain a large size. One great advantage in growing this variety for decorative purposes out-of-doors is that it may either be protected in the beds or position in which it stands, or be dug up and wintered in any dark shed or cellar, where, although it loses its foliage, the stems break and start away again in the spring, when they are little, if any, the worse for the treatment. Any one having plants of this kind and wishing to increase them, will find that the most ready way of doing so is to cut off a few of the largest and most fleshy roots, which, divided into about 2-in. pieces and buried in sharp sandy soil and then placed in a brisk bottom-heat, will soon break and form useful plants by the end of May.

Hedychium Gardnerianum, although generally treated as a stove plant, is sufficiently hardy to stand out in ordinary winters if planted in light, well-drained soil and protected with half-rotten leaves or any thing of that kind over the crown. Fine as it is grown under glass, it is much more so turned out with plenty of root-run, and, when so accommodated, is a valuable plant for forming bold clumps, or for massing in the foreground of shrubs, the uniformity of which it helps to break up and define. By dividing and starting any now, they will get well advanced by June, and may then be planted with safety.

Another capital plant for the same kind of work, or for grouping near lakes or ponds, is *Arundo Donax*, the tall reeds of which, towering some 10 ft. or 12 ft. high, and clothed with gracefully drooping foliage, have a very striking effect. It is to be feared that the hard winter we have had will have injured plants of this where not protected, but a slight covering over the crowns is always sufficient to insure their safety. Any division or planting should be carried out in April, just as the young shoots are pushing through the ground, as then one can easily see where to thrust in the spade, and the injured parts caused by so doing quickly heal over when growth fairly commences. To associate with the last named, *Arundinaria falcata* and *Bambusa Metake* should not be forgotten, as they are both plants, even in their young stage, that are exceedingly ornamental. *A. falcata* is the most elegant-habited of the two, but *B. Metake* has the merit of being more hardy, and appears quite unaffected by the present sharp winter. Both of these do best in a deep, loose loam, where they can find plenty of moisture below, and, if they can get this and shelter, their growth is most rapid. *Phormium tenax*, too, delights in a similar soil and situation, and, from the flag-like appearance of its leaves, is well adapted for planting near water, where, if slightly protected around the base during the winter, it soon becomes established, and forms an object of great interest and beauty. The striped or variegated kinds are remarkably handsome, but at present all of these are too valuable to be risked outdoors, except during the summer months, when, if plunged in suitable positions in the sub-tropical garden, they produce a striking effect. Plants of the normal type may be bought at a very low price, and they likewise come readily from seeds, which, sown now in heat, germinate quickly and make useful-sized plants at about a year old.

Grevillea robusta, the leaves of which, in general appearance, are equal to any Fern, is one of the most elegant habited plants it is possible to have, alike valuable either for in or out-door decorative purposes, and it is specially adapted for arranging in the centres of beds, or interspersing among others of lower growth, to relieve their flatness. This, like the majority of those plants now to be alluded to, admits of increase by seeds; but these being somewhat hard, germinate with more freedom if soaked for a few hours in a little tepid water before being sown. Besides being so useful for the purposes already specified, young seedling *Grevilleas* having healthy foliage down to the pot, form exceedingly graceful ornaments for the dinner-table, and when of larger size, come in admirably for assisting in the embellishment of greenhouses and conservatories during the winter. Next in point of gracefulness to the last-named, is *Acacia lophantha*, a plant of singular beauty; if seeds are sown now, and when up nursed on in gentle heat, they will be quite large and strong enough for turning out by the first week in June. *Ricinus*, or Castor Oil plants, are all very noble looking subjects, but the most remarkable among them is *R. Gibsoni*, which has leaves almost as rich and highly coloured as the well-known *Iresine*, now so much used for

bedding. I think the most telling group of fine foliaged plants I ever saw, was one formed of the above-named *Ricinus* and *Melanthus* major, the contrast between the two—the one so light and silvery looking, and the other of such a fine dark bronzy hue—being such as to arrest attention at once, and produce a most pleasing effect. As the *Ricinus* are up within a few days after being sown, and the plants grow so rapidly afterwards, the seeds should not be put in till the end of April, otherwise the plants either get too large before it is safe to venture them out, or if confined to small pots become stunted, and lose their lower leaves, which greatly detracts from their beauty. On the other hand, the *Melanthus* major cannot well be sown too soon, as it is not only slow in germinating, but takes some time in attaining much size, even when nursed on in heat.

Other rich combinations of colour may be made by associating *Melanthus* with *Coleus*, using the first-named as a centre, or better still, with *Chilian Beet*, the brilliant tints of which are then made to appear all the brighter. The effect of this latter is considerably heightened by being planted on raised mounds or banks, so as to get a full play of sun and light behind the leaves, which are then translucent and show off to the greatest advantage. The best way to manage *Chilian Beet* is to sow seed singly in small pots in a little warmth about the middle of April, as then the plants can be transferred to their summer quarters without check. Solanums, such as *Warczewiczii*, *giganteum*, or other large-leaved kinds are grand decorative subjects that may be raised quickly and cheaply in any ordinary hot bed frame, and, if planted in rich soil form quite a feature in the subtropical garden during the summer. *S. marginatum*, although not so large or strong growing, has handsome silvery foliage, and blends well with *Ricinus Gibsoni*. *Cannas* are quite indispensable, the contour and form of their noble foliage being such as to commend them for extensive use in all arrangements where fine-leaved plants are required. The growth of these, like most others already alluded to, is so rapid that seed sown at once will afford plants late in the spring. The strongest and best, however, are such as are obtained by saving the old roots in the autumn, and dividing the same now, which, if started in rotten leaves in a frame, lift well when required for use.

Echeveria metallica is another useful plant, either for forming groups among other succulents, or in raised mounds with the ground carpeted with *Sedum lydium* or other prostrate plant of the same or a similar nature, that the harmony between them may add the connecting link, as it were, and render the whole complete. The fine massive form of this *Echeveria* likewise makes it valuable for dot plants in carpet bedding, where, with *E. retusa*, it generally takes a very prominent part. It propagates readily during the summer by means of leaves or pieces of the flowering stems put in full sun in the open ground, and it may be raised from seed sown on the surface of finely-sifted soil, kept moist, and covered with a bell-glass till the plants make their appearance.

Acanthus latifolius has also large, glossy foliage, and comes quickly from seed. Plants of it in shrubbery or herbaceous borders, when in full flower, are fine-looking ornaments that are sure to command attention; but, being of strong growth, they require plenty of room.

Another plant of remarkably bold type and pleasing green foliage is *Wigandia caracasana*, a really fine subject for the sub-tropical garden, which, if sown now in strong heat, nursed, and potted on, will be quite soon enough for the purpose. As most of the above require rich soil, the positions they are to occupy should now be prepared by being trenched and heavily manured, so as to be in readiness for planting before the busy season arrives.

S. D.

Summer Treatment of Old Cyclamen Bulbs.—In reference to the inquiry made by "Star" (p. 221), I may state that my reason for recommending the bulbs to be planted out was in order to simplify the watering, as I know that many fall simply through the roots being injured by giving too much water whilst the bulbs are starting into growth. Placing them in the open ground obviates this danger, and by the time they are ready to pot, fresh fibres and new leaves are formed, when water may be given without injury.

"Star" cannot, therefore, do better than follow a system which has produced such good results. I used to treat old bulbs much in the manner described by "Star," shifting them out of 4-in. into 6-in. pots, and gently shaking out some of the soil when quite dry from them in 6-in. pots, giving fresh drainage and working in a little fresh soil, replacing them in the same sized pot, as I found by thus treating them, and administering weak manure water when in full growth, they succeeded much better than when transferred to larger pots. They were looked through the first week in July, but the bulbs were placed for a time in a frame, and were carefully watered until they had struck root, for I found that when exposed to heavy rains, many of the young fibres perished. I found, too, that they grew faster when thus sheltered, and, forming their flower buds sooner, they came more quickly into bloom. I may add, that I have always considered that two-year-old bulbs give more satisfaction than those which have exceeded that age.—J. CORNHILL.

NYPHÆA OBSCURA v. N. ROSEA.

SUCH is the heading of an article that appeared in the January number of the "Botanical Index" (an excellent periodical issued by Mr. L. B. Case, of Richmond, Indiana, U.S.A.), in which is reproduced and commented upon a short note that I communicated to THE GARDEN last summer on *Nymphaea odorata* minor. There is evidently some misapprehension as regards the information which I wished to convey, or the writer of the comment cannot be justified in suggesting the re-naming an already aptly-named and well-known plant. In order to set the matter in a clear light, and to obviate the necessity of referring to back numbers of THE GARDEN, allow me to quote both the note and the comment in question. Here is what I wrote:—"Nymphaea odorata minor is the variety named by Pursh as rosea, to which name it may justly lay claim, as the plant which we noticed in flower lately in the Kew collection confirmed. It is much smaller in every part than the type; it has the same dark purple colour on the under side of the leaf, and also the attenuated lobes. The blossoms, which are about 2 in. across, have the outer petals deeply tinged with rose, a colour which contrasts finely with the fringe of golden stamens. Though much inferior to the recently introduced rose-coloured variety of N. alba, it is, nevertheless, a distinct and valuable kind." Concerning this, the writer in the "Botanical Index" says:—"According to Sir Joseph Paxton, there is already a variety of *Nymphaea* with pink flowers, from the East Indies that received the name of 'rosea' in 1803, which, of course, must take precedence, and if the rose-coloured variety of N. odorata is distinct enough to warrant a separation another name must be chosen. With this idea in view we selected the name 'obscura' as the most suitable one for the variety; at least, it expresses the fact as well as any name can do. All plant collectors are aware of the disposition of plants with white flowers to produce bluish, brownish, yellow, flesh-coloured, or pink and rose-coloured flowers, while plants with coloured flowers are continually producing albinos, or, at least, flowers many shades lighter than the usual colour, the generally accepted types. The practice of multiplying species or even varieties upon such obscure and indefinite points may be excused in a commercial point of view, but it certainly is a source of great confusion in botanical nomenclature." The last sentence would lead one to infer that I am the offending party in calling the plant in question by the name of minor, but I can assure the writer, on no less reliable an authority than the "Flora of North America," by Torrey and Gray, that this variety was named minor many years ago by Sims, an old English garden botanist, and it has been known under that name by both botanists and cultivators ever since. I mentioned the name "rosea" given to it by Pursh merely in allusion to its synonymy, and also to show that that learned botanist observed the permanent character in the rosy tint of the flowers running parallel with its smaller size, even in a wild state; but as the name of minor is very applicable, and has priority of date, it must, as in the usual way, take precedence. The *Nymphaea rosea* alluded to by Paxton is merely a variety of either N. Lotus or N. rubra, and it would matter not if there were many more rose-coloured varieties, so long as their varietal name was preceded by the specific, and therefore I fail to see how in the present instance it can lead to "confused nomenclature." By forcing such an apparently meaningless name as "obscura" upon an old and well-known plant, without giving us any authority for it whatever, is, I consider, a breach of the laws which regulate botanical nomenclature.

W.

Golden-flowered Millfoil (*Achillea aurea*).—I am surprised that this old-fashioned herbaceous plant is not oftener met with in cultivation than it is. The peculiar shade of yellow which the flowers

exhibit is uncommon, and the habit being good and the whole plant very hardy and easily grown, it would be found suitable for many situations in the flower garden. I have seen it thrive remarkably well planted in the front line of a shrubbery, where it formed when in bloom a very distinct and somewhat striking object.—J. C. BYFLEET.

Primula denticulata.—It would be difficult to find any hardy plant that is more deserving of greenhouse or frame culture than this *Primula*. It is now beautifully in bloom, presenting a hue of colour that no other spring flower possesses. Starting with denticulata, then follow varieties of *Primula amena*, and later on come *P. japonica*, *sikkimensis*, *Parryi*, &c., whilst the smaller sorts are intermediate, filling up during the time when these large kinds are in bloom. *P. denticulata* and its ally *purpurea* may be raised freely from seed; a few pods from a plant of the latter last spring yielded me about 600 seedlings, the majority of which are just now coming into bloom. These will be planted out in a cool place in the open ground when the bloom is over, and there they will remain until November, when they will be lifted into 5-in. pots for blooming. During that time they make about three crowns. When planted out again the second year they produce from six to twelve crowns and make grand plants for 8½-in. and 9½-in. pots, producing large trusses of bloom. It is well, then, before again planting out, to divide the plants into several pieces in proportion to the number of crowns, as these will again produce large heads the next spring. The culture is simple, and so treated the crowns come stronger than when they are kept in pots all the summer. I find that this *Primula* roots deeply; indeed, it is difficult to wrench it out of the ground in the autumn with a strong fork. Before potting, it is necessary to shorten the roots somewhat, but no harm will be the result of this operation. As an outdoor decorative plant it blooms almost too early, except in very sheltered nooks, and these are generally too warm in the summer. Merely for a supply of out flowers a number of plants may be planted thickly in a frame with advantage.—A. D.

The Scarlet Clematis (*Clematis coccinea*).—When the "Revue Horticole" appeared with a coloured plate of a Clematis with bright scarlet flowers, and called it *Clematis Pitcheri*, we were not a little astonished. We had long cultivated *Pitcheri's Clematis* (*Clematis Pitcheri*), not only for its intrinsic beauty—for as a climber, with its large, dark purple, solitary flowers, it is a really handsome plant—but because it bore the name of one of the most courteous and genial of men of the "Old School" (Dr. Zinnas Pitcher, until his death the leading physician of Detroit) that it was ever our good fortune to meet. To have a plant thus endeared to us set aside by a new comer bearing the name, however brilliant it might be, was far from pleasant. The correctness of the "Revue Horticole's" plate was called in question by the "Gardener's Chronicle," whereupon came a correspondent of THE GARDEN, with a statement to the effect that *Clematis Pitcheri* was scarlet, for he saw the flowers of the first plant imported into France. Here was a muddle, and all about an American plant. *Clematis Pitcheri* was originally described by Torrey and Gray, in the "Flora of North America," with "purple" flowers. We collected in Texas a purple-flowered *Clematis* which we labelled C. *Pitcheri*, and which passed under the eyes of both Torrey and Gray, without any hint that it was not correctly named. Then our specimen in the garden, with its large purple flowers, if it be not C. *Pitcheri*, what is it? Either we were wrong and our European friends right, or vice versa, and we looked up the matter. It seems that a scarlet-flowered *Clematis* was first collected by Dr. James on Long's expedition, and was recorded as C. *Viorna*, variety *coccinea*, and has since been regarded as a scarlet variety of the well-known C. *Viorna*, until Mr. Buckley came across it and gave it the name of C. *texensis*, though Dr. Englemann, regarding it as a species, had called it C. *coccinea*. Without going any further into the nomenclature, it appears this scarlet Texan *Clematis* has somehow reached Europe, and is known in both France and England as C. *Pitcheri*, while it is here known only in botanical specimens. Whatever it may be, it is not *Clematis Pitcheri*. We are glad to say that we have got upon the track of the plant, through an intelligent correspondent in Texas, and expect to have it in cultivation the coming summer. Whatever the botanists may do with it, it promises to be a desirable plant for our gardens.—"American Agriculturist."

Wintering *Mentha Pulegium gibraltarica*.—In several positions this plant has perished completely. We use it largely for carpet bedding, and have had it in different situations. The best and healthiest roots we have now have been in a rather damp, cool situation on the north side of a bed of shrubs. A number of roots taken up in autumn, and planted in a cold pit, have all perished; and nearly all of those growing in southern exposures in the open air have turned brown, and now appear dead. Evidently it winters best in a situa-

tion where the sun does not shine full upon it. I shall work up my usual stock by taking those roots from the north border, pulling them into little bits, and dibbling them into warm pits. They increase rapidly in heat.—E. H.

Hardy Primulas.—It is interesting to note the difference which soils and climates make on these plants. In the south, in dry, warm soils, it is next to impossible to grow them at all, whilst in the north, especially in loamy soils of a good depth, they luxuriate to perfection. *P. cortusoides* acquires here a good size, and is a front rank hardy border plant. *P. amona* and its varieties have not succeeded here planted out permanently; but they were tried on warm exposures on the rockery, which may account for their failure. *P. japonica* does splendidly here as a border plant. The double varieties of *P. acaulis* do not succeed at all. *P. purpurea* and *alba* are the only sorts left, while just outside the garden are acres of single varieties of *P. acaulis* growing and flowering profusely. *P. denticulata* last year had on one plant fourteen of its lilac balls in perfection at one time. The same plant is pushing up again strongly this spring.—R. P. BROTHERSTON.

Pelargonium Daveyanum.—Mr. Williams will be glad to know that this fine old-fashioned hybrid Pelargonium is not lost. I have a plant of it in my possession at the present moment, and in the greenhouse from which it came to me there was, a few years since, a good stock of it. I believe, too, that it still flourishes in that home of every good old-fashioned plant, Wardie Lodge, Edinburgh. There are still several places where the Cape Pelargoniums are carefully cultivated and propagated. There is a capital collection of them at Kew; and Mr. Beech at Castle Ashby, and Mr. Baxter at the Oxford Botanic Gardens, deserve untold praise for the care and the energy which they have devoted to this most interesting group. I fancy, too, that Sir George Macleay and Mr. Green are well aware of the curiosity and value of the Cape Pelargoniums, and any visitor to the gardens at Pendel Court would soon discover that the time has not yet come when horticultural taste shall have so utterly degenerated, that a Cape Pelargonium is one of the good old things of the past. *Pelargonium flavum* is advertised in Meers, Haage and Schmidt's last bulb catalogue. Talking of good old plants, (as any one send me a cutting of the double Yellow Rocket (*Barbarea vulgaris* fl.-pl.), unfortunately, I have lost.—H. HARPER CREWE, Dryton-Beauchamp Rectory, Tring.

Snowflakes in the Wild Garden.—We have rarely seen anything more beautiful than a colony of the summer Snowflake on the margin of a tuft of *Rhododendrons* in the gardens at Longleat, where they were planted by Mr. Taylor. Some of the flowers were on stems nearly 3 ft. high, the partial shelter of the bushes and good soil causing the plants to be unusually vigorous.

Hardiness of Azaras.—Notwithstanding the notes that have appeared from time to time in reference to the comparative hardiness of these elegant Chilean shrubs, the past winter has committed much havoc amongst them. In the arboretum at Kew, those unprotected, comprising the handsome *A. microphylla*, *dentata*, *Gilliesii*, *integrifolia*, &c., are killed, but *A. integrifolia* and the variegated kind trained against the wall of one of the houses are not much injured. Fortunately none are so rare but that they may be readily replaced.—W.

Tacca pinnatifida.—This plant, to which allusion was made at p. 266, under the name of *Ataccia pinnatifida*, closely resembles an *Amorphophallus* in its habit of growth, having a solitary pinnatifid leaf, borne aloft on a stout petiole from 2 ft. to 3 ft. in height, while its bearded inflorescence is very similar to that of *Ataccia cristata*, a well known stove plant from Malacca and Perak. This *Tacca*, however, is an economic plant of some value, being largely grown by the Sandwich Islanders under the name of "Pi," and a peculiar kind of Sago is obtained in quantity from its underground

tubers, and used by them as food. It grows very freely on the sandy soil near the shores of many Malayan islands, but is but rarely used there, as the Sago Palm yields an abundant supply, and Rice is there more plentiful.—F. W. B.

Calceolaria amplexicaulis.—In the notice of *Calceolarias* (p. 259) I was glad to see mention made of *C. amplexicaulis*, an old favourite of mine, and one that used to be in great esteem in Hertfordshire for bedding, a purpose for which it is one of the best and most continuous blooming kinds that can be grown. The way in which it is managed in gardens in the county just referred to, is to plant it in small circles on the Grass among other beds, where it is tied and trained to sticks placed and brought together at the top, something after the manner in which they are placed over a basket of plants when sent out from a nursery. Thus managed, they form magnificent pyramids, and soon hide the supports; but it is only in moist, cool soils that they do this, although this particular species will stand more heat and drought better than any other with which I am acquainted. Its colour is a very soft lemon; it is very free in habit, and, where the soil suits it, sends up a quantity of suckers that keeps up a constant succession of flowers till quite late in the autumn. The long period of time during which I have known this variety I have never once seen it diseased, a failing to which all others are exceedingly subject, and which makes them so uncertain. It is a kind which I can, therefore, strongly recommend. I am sure that any one who once has it will not readily part with it.—S. D.

Scilla sibirica.—The flowers of this Squill being of a deep and lovely blue, contrast vividly with the pure white of the Snowdrop, and form a feature of singular richness and beauty in the spring garden. If grown in the open border, care should be taken not to injure the bulbs by digging or hoeing. The roots should be allowed to remain in the ground for a lengthened period, like those of the Crocus and Snowdrop; and if the clumps get too large, they can be broken up with great ease, just as the tips appear through the soil than at any other time. Even when an abundance of roots is formed, large clumps will divide easily into several smaller ones, which may be at once replanted without any danger. For pot culture, it is well to proceed in a more methodical manner; and, looking at the great beauty of the flowers and the early period at which they appear, it is remarkable that this Squill is not more largely grown in pots for decorative

Snowflakes in the Wild Garden.

Purposes. A piece of ground, deeply dug and moderately manured, should be planted with bulbs in the autumn in small clumps of about six roots to each. If these be all sound (and this is not always the case with imported bulbs), each plant will be large enough to lift into 5-in. pots after a year's growth, that is, these newly-imported roots should be in the ground at least eighteen months before they are potted; this makes two relays of bulbs necessary. Once a stock is obtained, provision for an ample supply of flowers in pots is easy. The clumps should not be kept in the pots, but should be re-transferred to the open ground as soon as the flowers have decayed.—A. D.

Seedling Aubrietias.—The introduction of several rich dark-coloured Aubrietias, such as A. Campbelli, Eyrei, and Hendersoni, has lent additional value to these charming spring flowers for bedding purposes. Mr. Ingram, of Belvoir, has raised a pink kind, the flowers of which are small, but the colour distinct. I was fortunate enough to get a batch of seedlings last spring that furnished a number having very deep rich colours of quite a violet tint. Patches of these on rockwork, or masses in beds, with red and white Daisies and similar hardy bedding plants, would produce a striking effect in the spring garden. When the plants have done blooming, they should be lifted, pulled to pieces, and replanted in some shady place where they will make fresh roots, and become strong by the next winter. Treated in this manner, they will be found to give the greatest satisfaction.—A. D.

THE FRUIT GARDEN.

GOLDEN CHAMPION GRAPE.

THOSE who for a few years back have been in the habit of seeing some of the leading West of England Horticultural Exhibitions will have noticed the finely finished Grapes, especially Golden Champion, shown by Mr. Shore, gardener to the Rev. J. Heyworth, Henbury Hill, near Bristol. Being in the neighbourhood about the middle of this month, I felt desirous of seeing the Vine which produced these finely grown Golden Champions, a kind with which more fail than succeed. There were originally four other Vines in the house with their roots inside, but they succumbed to the Phylloxera, and I understand that there is still some of the insect on the small portion of roots belonging to this Golden Champion inside the house. It was grafted eleven years ago on Ingram's hardy prolific Muscat, a sort, if I recollect rightly, "let out" by the late Mr. Standish, of the Ascot Nurseries, but one which did not meet with much favour. The Vine in question now covers a large portion of roof, and the present season's shoots are remarkably strong, and showing quantities of large bunches, some of which looked as if they would weigh from 3 lb. to 4 lb.; none of the bloom was open, but the crop, so far as it has advanced, gives promise of being, as hitherto, very fine. The Vine is planted inside, in a small stone-enclosed space, so limited as to have no influence for or against the condition it is in. The roots pass through the wall to the outside in the usual way, first under a walk, and from thence through the immediately adjacent garden wall into a Grass field, where they exist in abundance, but no preparation has there ever been made for them, no fermenting matter to warm them, or anything to keep the summer's absorbed heat in or winter's cold rain and melting snow out. The case represents extremely opposite conditions as regards the temperature of the roots and top, much greater than I, or I suppose any one else, would recommend or through choice adopt. But there is this Vine, after such a winter as we have had, one amongst untold numbers of other Vines throughout the country in a similar state, giving silent but irrefutable rebutting evidence against the opinions of those who appear to look upon a warm condition of the roots as inseparable from successful Grape growing. Its present treatment, I understand, is just such as it has from the first received, and from the time when it first came to a bearing state it has always done equally well.

T. BAINES.

A VISIT TO THE THOMERY VINEYARDS.

THE village of Thomery lies about a mile and a half from the railway station, and a good bit of the forest of Fontainebleau is traversed between the two—the trees, Oak chiefly, standing thickly together like seedlings in a hotbed. Almost as soon as one emerges from the dense shade of the wood, he finds the road bordered on one side by Vine walls, and on the other by a rough fence, over which the field Vines scramble in a semi-wild state, like Blackberry bushes, and down in the valley below lies the village surrounded on all sides by Vineyards—some small, and some large, and all enclosed and subdivided by low mud-built walls, on which the Chasselas de Fontainebleau Grapes are grown, the fields being cropped with the commoner wine-producing sorts, upon which comparatively little pains are bestowed. Far out of the village the walls are clothed with Vine and Pear trees, trained in the most perfect and methodical fashion, and bearing heavy crops of fruit. The Grapes were not ripe at the time of our visit, early in August, but the Pears were; some sorts had indeed been gathered. The trees were not protected in any way, though the fruit was hanging temptingly ripe within arm's-length of the highway; and the border in which the roots of both Vines and Pears grew was only about 2 ft. wide, and was supported by a dry stone wall built along the roadside. A group of whitewashed buildings, a little way from the road, looks very much like a Scotch farmstead; but a peep within the enclosure shows that the arrangements and appliances are of a different order, and relate exclusively to the culture of the Vine. The walls of the court, the dwelling house, and sheds, &c., are all covered with the Chasselas de Fontainebleau (Royal Muscadine) Grape, and at a glance one can see that every shoot, and almost every leaf, is trained in its allotted space, and all the laterals stopped and pinched as if they had been newly gone over. It is the same in the village. Every wall appears as if it had just been newly whitewashed, and every cottage on south, east, and west exposures is covered with a mantle of green Vine foliage, under which the bunches hang in profusion, literally touching each other in some places. Every bit of available space is utilised, and not an inch more growth is permitted than is necessary to the successful fruition of the plant, which is cropped as heavily as it will bear. An English cultivator is rather disconcerted at the appearance

of the Vine borders in front of the houses—the border is the street, and is paved with large boulders right up to the stems of the Vines. Yet both wood and foliage are remarkably good and clean—scarcely any trace of spider or mildew to be seen—and the leaves large and leathery, and of a substance never seen in an English Vineyard. Of course, the thrifty cottagers simply utilise their walls in this way, and attend to the training and general culture of their Vines in the evenings—just as the English cottager looks after his Potato plot and garden when his day's work is done. In the Vineyards proper, devoted to the culture of dessert Grapes, Vines are trained to low walls from 6 ft. to 10 ft. high, and coped with brick tiles, the parallel strips of ground between the walls being devoted to the production of common wine-producing Grapes chiefly; some of the better sorts are also trained on espaliers in the open ground. There is nothing in the culture of the Vine at Thomery that particularly arrests the English Grape-grower's attention, unless it be the skill and method displayed in the training of the Vines, so as to get the greatest amount of fruit from a given space, combined with the use of the cheap and simple, not to say primitive, but perfectly effective appliances employed to meet the end in view. There can be no doubt, we think, that the French excel us in making the most of means and appliances. Where we spend money they spend extra labour and attention, and with better and more constant results. This fact forces itself upon the stranger at once.

The winter of the north of France is more severe than that in this country, as is indicated by the single fact that the *Arcaurica imbricata* is not hardy there, and consequently not planted as an ornamental tree, and the spring frosts are also severe, yet we are assured that the Vine crops at Thomery seldom or never fail, although the protective appliances—old-fashioned copings and sheets—are much the same as those used in this country fifty years ago or more. Expensive patent glass copings and such like are unheard of. Brick, deal, and plaited-straw copings, 9 in. or 1 ft. wide, were shown at the Paris Exhibition, but no glass ones, by French makers at least. Our settled conviction is that there is nothing to hinder dessert Grapes from being grown in the south of England just as successfully as at Thomery, and with the same means, if the cultivator would take the same amount of pains in their culture. Crops would undoubtedly be a little later in England, but not much, and it is perfectly possible to ripen Grapes after the autumn frosts set in. The Muscadine ripens in August and September at Thomery, and on espaliers later; but behind the house of M. Rose Charnoux, who is one of the principal cultivators in the district, there is an archway or covered walk, planted entirely with Black Hamburgs, or Frankenthal, as it is called there, which we were informed ripened a crop in October. Under this archway the bunches seemed to hang as thick as leaves, and were all hand-thinned.

The spur system of training, in some form or other, is generally adopted. When the Vines are trained vertically, they are planted 16 in. apart and the shoots are mostly trained from one spur, 8 in. or 9 in. apart, and as often as otherwise the shoots bear two bunches, each about half a pound in weight. It may therefore be guessed how heavy the crops are. We have heard of 40 lb. to 20-ft. rods in this country, the canes being trained 4 ft. apart, but the Thomery growers exceed this in some instances, as regards the Vine rod, and generally we should say as regards space. On one young Vine of Foster's Seedling, which is becoming a favourite for wall culture, we counted eighteen bunches on a rod about 5 ft. long, and we estimated the bunches at 1 lb. weight apiece; some of them would be 2 lb. Indeed, we never saw much finer bunches of that variety. In favour it is not so good as the Muscadine, but its cropping qualities are a recommendation. The Vine that bore the above number of bunches had just a strip of wall 16 in. wide allotted to it like the others. No doubt the harder constitution acquired by the Vines, both in leaf and branch, enables them to bear such heavy crops. The wood of the Vines was brown and ripe to the ends of the shoots when we saw them, and a portion of the leaves had been picked off to allow the sunshine to get to the fruit to hasten its maturity. After the fruit begins to colour, this practice is not considered to be injurious in any way to the health of the Vines. The soil of the Vineyards is a brown, flinty-looking compost, and varies in depth from 18 in. to several feet, and the surface where the roots of the Vines are is mulched with decayed manure or litter. After the Grapes have been thinned, early in the summer, the after-culture consists almost wholly in training the shoots and pinching the laterals, the last being done by women who nip the shoots off with their fingers. The espaliers and bushes in the open quarters are not so particularly looked after apparently, but on the walls the laterals appear to be pinched as fast as they push, after the first stopping, little or no growth being permitted beyond the fruit, the exigencies of space demanding that every shoot be kept strictly within bounds. As to the quality of the Chasselas de Fontainebleau Grapes, they are

certainly superior to the same kind grown under glass at home, being well coloured, sweet, and of good flavour, very much superior to the foreign Grapes usually sold in this country during the autumn and winter.—"The Gardener."

CLEARING STRAWBERRY PLANTS OF RED SPIDER.

The writer of the calendar (p. 257) recommends that Strawberry plants which are badly infested with red spider should be thrown away when removed from the forcing house, but there is no need to resort to this extreme measure, as in their case the spider may be promptly and thoroughly exterminated. When the plants are removed from the forcing house, they should be placed in a sheltered situation for about a fortnight, when they should be dipped in a mixture of soft soap and sulphur, which will not only kill the perfect insect, but will also destroy its eggs. In preparing the mixture, about 4 oz. of soft soap to 1 gallon of water will be necessary, adding thereto enough sulphur to cover the whole of the plant after immersion with minute particles. The sulphur should not be thrown loosely into the water, but should be first formed into a paste which will effectually disintegrate it. On a plant thus smothered no living thing can exist, and in a fortnight the plants will be clean, and when planted out will grow away freely. Whilst dipping the plants the mixture must be kept well stirred and the water should froth. The sulphur will then adhere so tightly, that nothing short of heavy rains will loosen it. I generally employ one part black to two of flowers of sulphur. The black sulphur is very powerful, and should never be used under glass. It is indispensable that the foliage be well hardened before dipping the plants, or it is liable to be injured. I occasionally find that a few leaves get a little hurt, but when once the spider is gone the plants, if supplied with nutriment, start again vigorously into growth. Forced Strawberry plants yield a crop the following season when planted out, and therefore should not be destroyed. A well enriched piece of soil and an occasional watering in hot weather are all that they require.

It is inconceivable with what rapidity red spider will spread over a piece of ground in a hot, dry summer, and growers, as your correspondent wisely recommends, should be careful not to incur any risk. I have seen Scarlet Runners, bedding plants, and even Box edging almost ruined by this very small pest, and it is rare that Strawberry plants come out of the forcing-house entirely free from it; but, if treated in the manner just described, the little extra labour will be well repaid. The soil of a locality in which I once resided was very sandy, and consequently parched in the summer. British Queen grown under such circumstances was generally so attacked with red spider, that it could scarcely exist until dipping and syringing with soft soap and sulphur were resorted to. After that it grew as freely as the other kinds. This variety would appear to be peculiarly susceptible to the attacks of red spider, which fasten on it in preference to other kinds. To this cause may, I think, be attributed the inability to grow this highly-flavoured fruit in many localities. Plantations of it after bearing often die completely off, but if the plants were thoroughly syringed as soon as the fruit was gathered—choosing a period of dry weather for the operation—and then deluged with water, the ravages of this destroyer would be reduced to a minimum. These remarks apply more particularly to light, porous soils, where the foliage does not acquire the solidity which a strong loam imparts to it, and where it is more difficult to supply the necessary amount of moisture to the root.

J. CORNHILL.

Thatched Vine Borders and Vines Breaking Prematurely.

—Allow me to explain that when writing on this subject (p. 238) I accepted the advice given by Mr. Baines and others to cover Vine borders "early in autumn to retain the accumulated heat of summer" to mean the only thing apparently it could mean, viz., to cover the borders when the temperature of the earth was at its maximum, which it reaches in August, and does not subside very perceptibly till past the middle of September, within which period I apprehend "early in autumn" comes somewhere. I, however, accept Mr. Baines' latest explanation, but it does not in the least alter the fact, that by covering the border in autumn we start the roots much in advance of the tops. Indeed, it is an aggravation of a practice attended, as we have been told, by bad results in every way and under all circumstances. As to the retained heat of summer not helping to cause the Vines to break prematurely, I can only say that I have lately been taught that bottom heat causes an undue development of top growth, and I suppose Vines are no exception to the rule.—J. S. W.

THE KITCHEN GARDEN.

ENDIVES GROWN FOR TRIAL AT CHISWICK.

By A. F. BARRON.

ENDIVES are divided into two great classes.

1. *Curled Endive*. The *Chicorée frisée* of the French.—Leaves deeply cut or laciniated and curled.

2. *Batavian*, or Broad-leaved. The *Scarole* of the French.—Leaves broad, resembling Lettuce.

The collection was sown on July 1, and treated in the usual manner for an early autumn supply. The season being favourable, the autumn fine and open, they succeeded well, so that the trial was, in every respect, satisfactory.

1.—Curled Endives.

1. *Ever White Curled* (Vilmorin). See White Curled.
2. *Fine Curled Moss* (Vilmorin). See Moss Curled. A fine selection.
3. *Fine Curled Picpus*. See Picpus.
4. *Fine de Rouen*. See Stagshorn.
5. *Gloria Mundi* (Minier & Co.). See Green Curled.
6. *Green very fine Curled Summer* (Vilmorin).—Leaves about 6 in. long, resting close on the ground, with a broad, fleshy midrib, the edges toothed and much curled, of a deep green colour. Forms very large, full hearts, which blanch readily and early without much tying. Crisp, fleshy, and excellent.
7. *Green Curled* (Minier & Co.).—Leaves from 7 in. to 8 in. long, lying flat on the ground, very deeply cut and toothed, of a bright green colour. Forms large, full hearts, which blanch readily on being tied; somewhat liable to rot in wet weather.
8. *Green fine Curled Winter* (Vilmorin).—A good selection of Green Curled.
9. *Green Curled Ruffec* (Vilmorin).—A very good selection of Green Curled.
10. *Imperial Curled* (Vilmorin).—A variety of the White Curled, with broader leaves and not quite so much cut. Good.
11. *Laciniated Louviers* (Carter) (Vilmorin).—Leaves short, very deeply cut and laciniated in a singular manner; of a dull glaucous green colour. Forms close, full hearts of excellent quality, which blanch naturally to a good extent. This variety will not tie up; requires covering up to blanch thoroughly; very hardy.
12. *Large Ruffec* (Watkins & Simpson). See Green Curled.
13. *Louviers*. See Laciniated Louviers.
14. *Moss Curled* (Carter) (Minier).—Leaves very short, very finely cut and curled like Moss; of a bright green colour. Forms small, compact, full hearts of very fine quality. This variety is too small to tie up; requires to be covered up to blanch thoroughly. Fine for garnishing and for early use, but very liable to rot in moist weather, and is rather tender.
15. *Picpus* (Vilmorin).—Leaves long, lying flat on the ground like the Green Curled. Of a very deep green colour; deeply cut and finely curled, thick and fleshy. Forms very large, full hearts of fine quality. A very fine vigorous-growing variety; one of the best types of Curled Endive. First-class certificate.
16. *Rouen*. See Stagshorn.
17. *Ruffec*. See Green Curled.
18. *Stagshorn* (Vilmorin).—Leaves very short, very deeply cut; like the Louviers, but somewhat smaller than that variety; very hardy.
19. *Selected Green Curled* (Veitch).—A good selection of Green Curled.
20. *Wrench's Moss Curled* (Wrench). See Moss Curled.
21. *White Curled* (Carter) (Minier) (Veitch).—Leaves from 7 in. to 8 in. long, lying flat on the ground, deeply cut and finely curled; of a very fine pale green colour, hence called white. Forms fair-sized hearts, but requires tying up to blanch thoroughly; a very distinct variety in appearance, and hardy. First-class certificate.

2.—Batavian or Broad-leaved.

22. *Broad-leaved* (Vilmorin). See Round-leaved.
23. *Broad-leaved Winter* (Vilmorin).—Leaves long, broad; deep green, slightly toothed and wavy in outline; requires tying up to form hearts. A good, hardy, late variety.
24. *Fraser's Broad-leaved* (Minier) (Veitch). See Broad-leaved Winter, No. 23.
25. *Green Batavian* (Carter).—Leaves very long, narrow, forming small hearts. Worthless.
26. *Round-leaved* (Carter) (Minier) (Veitch).—Leaves from 10 in. to 12 in. long, broad, light green, toothed and wavy in outline, the outer lying flat on the soil, the inner incurving from the points and thus forming a close heart, which blanches naturally to some extent.

When tied up, a close, firm heart is formed, as white as ivory and of excellent quality. This is by far the best Batavian *Eudive*.

27. *White Batavian* (Carter) (Minier) (Veitch).—Leaves long, resting flat on the ground; of a pale green colour. Forms small hearts, which require tying up. Very apt to decay in moist weather. Worthless.—“Royal Horticultural Society's Journal.”

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The Dalmahoy and Regent Potatoes.—Allow me to testify to the correctness of “J. S. W.'s” description of Dalmahoy and Regent Potatoes. The White Don does better here as a second early sort than any other which we have tried. Mr. Baines is surely mistaken when he classes Victoria with the Regent. The cottagers about here show it as a Kidney in its flattest form. In its roundish form it is quite distinct in appearance, as well as in other points, from the Regent. I would recommend Walker's Regent as the best disease-resisting of the type.—R. P. BROTEBERTON.

—That the Regent and Dalmahoy Potatoes were identical at Chiswick cannot be disputed. About thirty samples on the aggregate were obtained from all parts of the country, and planted side by side. These samples had been grown in different soils and climates; the first year some were a little more forward than others, and the tubers of some handsomer than others. Sets were carefully saved of each sample, and the result of the second year's trial (confirmed by a third year's experience) was, that all differences had disappeared. In height, in the character of the haulm, in the colour and size of the flowers, there was no perceptible difference between Dalmahoy and Regent.—R. D.

—Without entering at all into the discussion as to whether the Dalmahoy, Regent, and others are distinct varieties or not, I can truly say that my somewhat lengthened experience of Potatoes has led me to arrive at pretty much the same conclusions as those which Mr. Baines appears to have come to, and, like him, I am clearly of opinion that any one who has the true Regent and a soil that suits it, can have none other at present among the many much vaunted kinds at all equal to it, or that will in any way approach it for quality and flavour. As to the American sorts, the most that can be said for the majority of them is, that they are heavy croppers, but I venture to predict that they will be discarded and forgotten in less than half the time the Regent has been in cultivation. Why the very name of this latter helps to sell others, for if I mistake not, the Schoolmaster was said to be an improved Regent, or to possess some of its qualities, and also Patterson's Victoria, thus showing that the great repulse it has gained may be used as a testimonial for others. No doubt there will always be buyers of new varieties of Potatoes, as there are of other novelties, and it is well there should be as an encouragement to raisers, but that does not alter the fact that old sorts are not yet beaten, neither does it appear likely that they will be for some time to come. Until I can find something better than Ashleaf, Regents, Flukes, and Rocks, I shall stick to these almost exclusively, as I have had quite enough of most of the others. Prizes given for Potatoes at a show are a delusion, for the adjudicators can know nothing of their merits for the table, and can only make their awards haphazard, except so far as the clearness of skin and shape may help in leading to a decision.—S. D.

Hardiness of Broccoli.—The evidence furnished by the state of the Broccoli plantations this season seems to me to be conclusive in favour of planting in an open, airy situation, and to plant far enough apart, so that the plants may acquire a hardy constitution, and build up a firm, hard growth. The late kinds with us have suffered little or no injury. Among newer kinds Lauder's Goshen seems a very hardy, desirable kind; Cattell's Eclipse, Wata's Excelsior, and Veitch's Spring White are also in good order, although the lower leaves are somewhat browned, and the plants generally are rather smaller than usual at this season; but the long severe winter will easily account for this. Such kinds as the Leamington, Cooling's Matchless, Early Penzance, Sussex Winter, and Veitch's Self-protecting have all suffered more or less, and those occupying comparatively sheltered situations most of all. Still there is not much harm done; and Cabbages planted thickly on a warm south border have already, since the change in the weather, made considerable progress, and will soon come into use.—E. H.

Red Genoa and New Giant White Tripoli Onions.—These two sorts have stood apparently unhurt with me here during this last winter without any protection whatever. The seeds were sown the first week in August on an open space in the kitchen garden. They came up very thickly, and were allowed to remain in that condition, although against the old rule as to leaving them thick during winter.—J. WINFIELD, *Bulwich*.

ROSES.

ROSES PLANTED OUT AND IN POTS.

Pillar and Rafter Roses.—The great thing to contend with in the cultivation of Roses on the rafters, pillars, and walls of green-houses and conservatories is their liability to be attacked by aphides and red spider, and the difficulty that besets their destruction in such situations. In the case of aphides it will frequently happen that climbing Roses in these positions are the only subjects in the house affected, and, where the structure's non-attachment to a dwelling house makes the fumes of Tobacco less objectionable, there is still the cost of the material in fumigating a house for the very few plants thus infested, and to syringe them with Tobacco water, Gishurst, Quassia, or other of the liquids used for insect destruction is generally out of the question on account of the condition in which these leave the woodwork and glass of the building. On this account I have always found it absolutely necessary to look over Roses in situations of this description every week at this time of the year, for, if allowed to become infested thus early, the coming flowers and tender foliage are injured. When the young growths are at all troubled with the aphides they should be at once dipped in Tobacco water. To prevent red spider, which, with the increased sun's warmth, makes its appearance very early upon Roses, little can be done in such positions except repeated syringing with clean water; this is often disagreeable in conservatories, &c., through wetting the flowers and foliage of plants that are better without it, nevertheless, it becomes necessary, and the work should be done in the mornings of bright days, when all upon which the water falls will be likely to get speedily dried up. It is well to regulate the young growths of plants in situations of this sort—both the weaker kinds and vigorous growers, like *Maréchal Niel*, the climbing *Devoniensis*, and *Lamarque*, thinning out the weak spray not strong enough to bloom. One of the principal things to be attended to in the cultivation of Roses in these positions is the encouragement of strong young shoots from the base, or sufficiently low down the stems to furnish the particular places they happen to occupy; when this is not done there is generally a disposition in Roses so grown to make all or the greater part of their growth towards the top, leaving an unsightly portion of bare stem. With sufficient forethought in pruning this can be avoided by, from time to time, cutting some of the old strong shoots low enough down to the point from whence they spring, which will cause the lower eyes to break. Where this was not done when they were pruned in the winter before growth commenced, and there is an evidence of their getting into the condition described, there need be no hesitation in shortening a portion of such shoots now. Roses so grown, particularly where there is more heat employed than is necessary to keep out frost, are always apt to suffer from mildew, caused by the admission of cold external air in direct contact with the young foliage; during this month, when accompanied with bright sun, the air is often very keen, and care should be taken to admit it where it will be least likely to affect them injuriously.

Roses in Pots.—Attend regularly to the routine requirements of these in their different stages, whether they are plants that have been forced through the winter and are now making growth that will furnish successional flowers, or those that are coming on with their first bloom. Use every means to keep them clear from insects; one of the best ways of effecting this I have found to be syringing with water slightly impregnated with soot—say, a large handful to three gallons, well stirred up, and then allowed to remain for two or three days, pouring it gently from the vessel in which it has stood, so as to leave the sediment in the bottom. Soot is so disliked by insects generally that thus applied it has the effect of rendering the foliage distasteful to them. To plants that have been growing through the winter liquid manure will now be of the greatest assistance. Roses will endure it stronger than many plants, and I should recommend soot to be added to whatever else is used. Not only is it invigorating but I have remarked that plants in pots which received it in a liquid state were always less subject to the attack of insects than where it was not used. It is also the best and safest eradicator of worms. There is another matter connected with Rose growing in pots in private establishments which often escapes notice. By some a Rose in the winter and early spring may be reckoned simply as a Rose, little regard being paid to the form of the flower, yet I frequently hear the question asked by those who grow their own Roses, “How is it that the beautiful, long, half-expanded buds to be seen in the London flower shops are so superior to those of home growth?” It is simply a matter of a little manipulation; the London forced Roses have each a thin ligature of bast tied round the buds at about one-third the distance from the base of the flower when they have slightly begun to open, and there this ligature is allowed to remain until the blooms

are out and ready for use. This permits the development lengthwise without allowing them to expand. At first sight such work might appear tedious, but a small amount of practice will enable anyone in a short time to go over a considerable number of plants and tie the blooms in this way. The bast must neither be too tight nor too loose, nor is it possible to convey in writing the exact point to which tying should be carried, as different varieties require to be somewhat differently dealt with in this matter. A little observation will, however, soon assist those engaged in securing every bloom thus grown in a very much handsomer condition than if left to itself. Any of the earliest forced plants that do not show an ability to produce many more flowers should be transferred to cold pits or deep frames, where they will be gradually hardened off. On no account should they be turned out into the open air until the season is sufficiently advanced. Where room in continued warmth can be afforded for such plants to go on and make further growth, it will tend to much increase their size and strength, by which their blooming for the time to come will be proportionately influenced.

Outdoor Roses.

Pruning.—The remaining portion of Roses may now be pruned I take it for granted that those for whom these remarks are intended require their Roses for general purposes, and not for exhibition. With dwarfs, either grafted or on their own roots, and which are cultivated on the pegging-down system, the old shoots that were last year trained down should be cut out altogether in the case of very strong established young plants, and shortened in the case of such as are weaker, or that have only been planted one year. As a matter of course, the last summer's shoots that have sprung from the base of these dwarf pegged-down plants will now be in an erect position. With strong plants, the weakest of these may be completely cut away, shortening the strong ones in proportion to the space to be covered when pegged down. Whatever manure is needed should then be put on and forked in without disturbing the roots, and, if the nature of the land require it, some more may be put on the surface by way of a mulching. The necessity for doing this before the shoots are pegged down, an operation which should be done at once, will be obvious. Any Roses on walls that yet remain unpruned should have this work no longer delayed, for even in the northern portion of the country we are not likely to get frost that will injure them after this time. On account of the difficulty frequently experienced in applying manure to the roots of Roses in such positions, they are more liable to get into a weak condition from want of it than when planted elsewhere; but if they are to be kept in a free-growing, satisfactory state, manure, in either a liquid or a solid form, must reach the roots in some way.

Pillar Roses, and also those on arches spanning walks, or in similar positions, need to be left in a way that will exhibit more freedom of shoot development than would otherwise be necessary, as it often happens that in pruning and training the work is done in a manner which gives them an even-clipped appearance, a character so desirable to avoid. Instead of all the shoots, weak and strong, being cut to a uniform length, it is much better to thin out a great number of the weaker growths, leaving each year the stronger ones out to different lengths. In this way by the time they get into leaf they will have a free, open appearance.

Rose Hedges.—There are no more beautiful objects in a garden than divisional hedges, or screens, composed of Roses, when these are managed as they ought to be, which is often far from being the case. Roses in an ordinary hedge-like form, when in flower, are certainly most effective, but the more or less even outline is an objection. The most pleasing arrangement which I have ever been able to hit upon, when Roses were employed as a divisional screen, was fixing a light, thin, inexpensive sort of improvised trellis-work, made of iron rods overlapping each other so as to support the plants, and keep the whole from being blown out of shape by strong winds. It was intentionally so far uneven in height, that it varied from the lowest points, which were not more than 4 ft. 6 in. out of the ground, up to 7 ft., the highest. Until the Roses had grown so far as to cover it the appearance was not such as to satisfy those who are fond of everything trim and even. The irregularities of height were still further brought out by the different colours of the kinds planted, and which varied from the deep crimson Bourban to the Ayrshire Dundee Rambler (white), the pale flesh-tinted Gloire de Dijon and others of similar habit that occupied places on the trellis which admitted of their growing higher than the others, that produced flowers of a character more in keeping with the generally accepted form which Roses ought to have than the climbing kinds. They were old sorts, such as *Châtondôlé* (crimson), *Madame Plantier* (white), *William Jesse* (crimson, shaded with lilac), *Paul Ricaut* (rosy-crimson), *Juno* (pale rose), *Coupe d'Hébé* (pink), and *Blair No. 2* (blush). The

advantages this light ironwork had over a wooden fence that would give a light appearance were that it cost less to begin with, was less objectionable to the eye and more durable. T. BAINES.

Roses with their Roots in Inside and Outside Borders.

—As bearing on the question sometimes discussed as to the relative temperatures of borders inside and outside of glasshouses and their effects on the growth of plants, I have observed that in our Rose house here—a cool house, where the growth is natural—*Maréchal Niel* on a Brier stock, with its roots growing in a cold, stiff, clayey loam border outside, facing the east, is making growth quite as early as the same Rose is doing in an inside border, or rather bed, as the soil is raised some 2½ ft., and is enclosed all round by a brick wall. This should make the soil at least several degrees warmer than that outside, but the growth shows no advantage. It is, therefore, evident that the action of the plant is more governed by the atmospheric temperature than by the terrestrial condition of the roots. I have also observed that that charming tinted Tea Rose *Homer* has the advantage of all others in the earliness of its growth, which is quite 2 in. in advance of *Maréchal Niel*, although this sort also has its roots on an outside border, but on the west side. This is a capital Rose for house work, as it grows freely, does not push away several long, woody growths, but gradually covers the trellis. Some kinds, such as *Lamarque*, grow away with a rush, having a few specially long shoots that soon reach the top of the house. These should be planted alternately with the more bushy kinds, and thus the house will be evenly covered. Cuttings of *Maréchal Niel* put in just after the bloom was over proved a great success. These are now strong enough to be shifted into 8-in. pots, and, doubtless, will presently each carry some fine blooms.—A. D.

PROPAGATING.

Cutting of *Cineraria maritima* compacta.

CINERARIA MARITIMA COMPACTA.

—This beautiful dwarf, white leaved variety, the finest on the class to which it belongs, is best increased by means of cuttings, made as herewith shown. They should be inserted in February and March, and should be taken from plants that have been placed in a warm greenhouse. Four-inch pots, drained well, and filled with fine, sandy soil, are those most suitable for the purpose. Insert the cuttings, and tighten them well in; give them a good watering, but not over the leaves, and place them in the cutting box on a gentle bottom-heat, in which they will strike root in about ten days. They may then be gradually inured to the air before they are taken out. If any of them require water before they are rooted, they must be taken out and watered, so as not to damp the leaves. This *Cineraria* may also be increased in September by means of side shoots taken from plants out-of-doors and put in a close frame on a cold bottom. When rooted, place them in the greenhouse for the winter. H. H.

Centaurea ragusina from Cuttings.—I quite agree with all that "D." says (p. 250) in favour of this charming silvery-leaved plant; but doubtless many find it difficult to get a stock of it, either from seed or cuttings, compared with the facility with which soft-wooded plants are, as a rule, increased in such ways. For several years past I have raised it from seeds; but, although by no means a novelty, the number of seeds in a packet is so limited, that it takes a good many packets to get 400 or 500 plants. With, however, a few plants planted out in good soil in spring to start with, a good many side shoots may be obtained from them in autumn. These, if taken off with a heel of old wood and inserted singly in 2½ in. pots, tying the foliage up to a single stick, and plunged in a cold frame, will strike root with scarcely any loss. The old stools may be lifted and wintered in a cool house, and at this season, if subjected to a gentle heat, they will yield a quantity of side growths for propagation.—J. G.

PARK ROADS.

LONDON is not the only place (see p. 88) where so-called macadamising is carried out by contractors and others, nor is the "Pall Mall Gazette" the only paper that has directed attention to the matter, for the same thing has been adverted to in THE GARDEN more than once. On roads and drives, on private estates, and even on the highways, which are supposed to be managed by people who understand their business, plenty of examples of macadamising are to be found that would make the hair of the original inventor of the system stand on end were he alive. The real truth of the matter is that the majority of people who have to do with road making only know the system by name, and have a vague idea that it simply means spreading plenty of stones on the ground and nothing more. Hence it is that so many roads are a continuation of heights and hollows, which are always being repaired with no better result, and to the continual inconvenience of traffic and discomfort of pedestrians. Few people know how easily a good and properly macadamised road can be made, or understand how excellent and enduring such a road is. A man who understands the system, and sees it carried out properly will make a better road with a few inches of broken stones than others will make with three times the quantity of material, not to mention useless labour. Macadam cared very little what sort of a bottom he had to deal with if it were not an absolute morass, and he was not often deterred by that. "For a road," he says, "it is not necessary to lay a foundation of large stones, pavement, &c., as it is a matter of indifference whether the substratum be hard or soft, and, if any preference is due, it is to the latter." These statements look like heresy compared with much that we have read on road and walk making, but the great road maker was right, nevertheless. First of all, whatever the bottom was like, he took care to see that the ground had evenly settled before the stones were spread upon it, that there might be no subsidence in any part afterwards to cause inequalities, a matter which is often overlooked. When the roadway had to be prepared, large stones dug out of the ground, or any inequalities to be made up, the ground was afterwards left to settle before proceeding further with the work. In putting on the stones quite as much care was exercised. First, the hardest stone in the district was procured—granite, flint, or whinstone; next, it was broken to the regulation size—in pieces about 1 in. in diameter, though a rougher size will do; and, lastly, the stones were not laid on the road, but spread shovelful after shovelful to the depth of from 6 in. to 10 in., which was considered sufficient for general highway traffic. The road was made slightly higher in the centre than at the sides, to throw off the water, as the object was to form an impermeable crust that would keep the water from percolating to the bottom, thereby rendering it soft and causing it to work up, the necessary drainage being, of course, secured in the usual way. This is macadamising in the proper sense of the term, a system which has nearly superseded every other, but it is the attention to trifles in carrying it out that makes perfect work. For example, many people would attach little importance to the stones being broken or angular, and be quite as indifferent about the mode of spreading them on the road; yet these are two of the most important points. The use of water-worn stones of the same size, will not make a solid crust, because they yield to pressure, their round surfaces offering little or no resistance; but it is different with broken stones, which, when of uniform size, and clean, and properly spread on the ground set fast on the same principle as that of an arch. I have seen roads made on an extensive scale on this system, and had to make such myself, and I have never seen anything to equal them. Garden walks, which are often cut out deep and filled in in the bottom with large stones, may be made on Macadam's principle with far less trouble and with much better results. Broken stones, to the depth of 2 in. or 3 in., will be quite sufficient, and they should, after being spread on, be beaten even on the surface with broad wooden rammers. This sets the crust effectually at the beginning. Afterwards a thin coating of clean gravel should be spread upon the surface to hide the stones, but no more. Such a walk is smooth and firm, and comfortable to the feet in all weathers; rain only washes it

clean, and frost has not the least effect upon it if the bottom be drained. The material holds no moisture to freeze; it is the accumulation of soft gravel on the surface of walks that freezes and renders them so muddy and uncomfortable afterwards. With us the stones are broken by a machine to any size we want them.

J. S. W.

PLATE CLXXIV.

TWO ALPINE FLOWERS.

The two Alpine flowers here figured are among the most beautiful yet introduced to our gardens, in which, however, they are not often seen in good condition. *Gentiana bavarica* is indeed very rare in gardens, as compared with *G. verna*, and rarely well grown. In size and flower this species resembles the Vernal Gentian, but is very readily known from that by its smaller Box-like leaves of a yellowish-green colour, and by all its very small stems being thickly clothed with foliage, forming close, dense tufts, from which spring flowers of the deepest and most brilliant blue, which, as the observer gazes at it in admiration, seems occasionally flushed with a slight tinge of deep rich purplish-crimson. The flower is even a shade more lovely than that of *G. verna*. The plant is a native of the high Alps of Europe. *G. verna* occurs in the same place abundantly; but, while it is found on dry ground, or ground not overflowed by water, *G. bavarica* is seen in perfection in spongy, boggy spots, where some diminutive rill has left its course and spread out over the Grass, not covering it, but saturating it so that when you walk upon it the water bubbles up around. There can be no doubt that we must imitate these conditions as far as possible if we desire to succeed with the plant in England. The best thing to do with it is to plant it near the margin of a rill that falls from a rock-work, taking care to let no *Carices*, *Couch Grass*, *Cotton Grass*, or other strong-growing subjects get near the spot, or they would soon cover and destroy the plant. It may also be grown in pots, plunged in coal-ashes or sand during the summer, sandy loam to be the soil used; the plants to have repeated and abundant waterings from early spring till the heavy autumnal rains set in, or to be placed standing half plunged in water. In all cases it must have free exposure to light.

AQUILEGIA GLANDULOSA is a very beautiful species with handsome blue and white flowers and a tufted habit. It flowers in early summer—a fine blue, with the tips of the petals creamy-white, the spur curved backwards towards the stalk, the sepals dark blue, large, and nearly oval, with a long footstalk. The leaves are much divided, the upper part of the stem covered with glandular hairs. It is a native of the Altai Mountains, and one of the most desirable kinds for the rock garden, or the select border, in well-drained, deep, sandy soil. It is increased by seed and by very careful division of the fleshy roots when the plant is in full leaf. If divided when it is at rest, the roots are almost certain to perish, at least, on cold soils. This plant thrives better in northern gardens than about London, though we have seen it growing freely at Slough.

J.

Variegated Funkias as Pot Plants.—The beautifully variegated forms of this useful genus have, during the last few years, been in great favour as edging plants for sub-tropical beds, and, being hardy, they meet the wants of many small cultivators, who, having a limited quantity of glass, cannot preserve more tender subjects; I have lately been pleased with the beautiful effect which these plants produce under glass in pots for indoor or conservatory decoration. A few established plants in pots were placed in gentle heat along with *Dentizias*, *Spiræas*, &c., and the clearness and beauty of the variegation rendered them exceedingly effective. Such sorts as *F. Fortunei argentea*, *F. japonica lutea*, *F. lancifolia albo-marginata*, *F. ovata variegata*, *F. undulata variegata*, are all exceedingly beautiful; being of easy culture, they cannot fail to succeed under the most ordinary circumstances. Good clumps, lifted in autumn and placed in pots just large enough to hold the roots, and plunged in leaves until Christmas, will, when introduced to gentle warmth, prove no mean rivals to many of the stove plants that must be grown in a high temperature the whole year round.—J. G.

ALTAI COLUMBINE. [AQUILEGIA GLANDULOSA.]

THE BAVARIAN GENTIAN [GENTIANA BAVARICA.]

GARDENING FOR THE WEEK.

Indoor Plant Department.

Tree Ferns are often grown much too warm and moist. Under such treatment they attain a larger leaf development, and frequently a deeper green tint than they otherwise would do; but so managed they are not nearly so useful, the result being that they generally soon outgrow the limits assigned to them, and if they have to be moved for decorative purposes to other places they are a good deal more susceptible of injury. This particularly applies to the well-known *Diocksia antarctica*, the distinct and handsome *D. squarrosa*, as well as to *Cyathea*, especially *C. princeps*, a plant often known as *Cibotium princeps*, which, though beautiful when grown with too much heat and moisture, soon gets so large as to smother everything else near it. The fine varieties *C. Burkei* and *C. Dredgei* are scarce and dear, but for all ordinary decorative purposes *C. dealbata* is not only one of the most beautiful of all Tree Ferns, but from the hard, tough, whalebone-like texture of its fronds, will bear more ill-usage than any other species. Some of the oldest fronds of all these plants will now begin to have a rusty appearance, but, unless in the case of specimens which are exceptionally strong, and that produce fronds larger than may be desirable, I should not recommend the removal of any of the old leaves that yet retain vitality until the young fronds in course of development are fully grown; they must now have plenty of water at the root. I by no means recommend their having too much root space, which is a great mistake as regards the cultivation of tree ferns, unless in the largest houses where head room is not limited.

Small-growing Tree Ferns.—Those handsome miniature Tree Ferns, the *Lomarias*, of which *L. cycadifolia*, *L. discolor*, and *L. zamiaefolia* are such beautiful examples, can be grown in small houses where the larger species could not be accommodated. These and also the well-known *L. gibba* will do better with warm greenhouse treatment than in a hot stove. *Brahea insignis* is another of the small representatives of arborescent Ferns, even superior to the *Lomarias*, but it requires more warmth.

Cibotiums.—Where those grand, wide-spreading, drooping-habited Ferns, *C. Schiedei* and *C. spectabile*, can be elevated sufficiently high in the Fernery to show off their beautiful fronds to advantage, there is nothing in the whole family of Ferns that surpasses them. They need a moderate amount of heat and more root space comparatively than the tall-stemmed kinds, without which they have usually a sickly yellow hue. If there be a disposition to confine their roots, they must be regularly supplied with weak manure water through the growing season. Where large fronds are required to mix with out flowers, it is a great advantage to have such as will last long in good condition. For this purpose the creeping, rhizomed *C. glaucescens*, or, as it is more generally known, *C. Barometz*, stands unrivalled. This is one of those strong-growing species that can be planted out on a mound in a moderately warm Fernery; for, although, if left uncontrolled, like most other strong growers, it has a disposition to encroach upon and smother smaller kinds, still, a free use of the knife in reducing the matured fronds during the winter season, when they will be found most useful employed in the way above mentioned, will always keep it within due limits.

Gleichenias.—These will now begin to grow apace, and, if, at the time recommended for general potting, there were left over any with insufficient room, this at once should be supplied, as there are no plants in cultivation with which I am acquainted that suffer so much from want of space to allow their creeping rhizomes to spread.

Gymnogrammas.—These are not generally so much cultivated as they once were, doubtless on account of their requiring a higher temperature than most Ferns, and also because they are of comparatively little service for cutting, yet there are some amongst them so distinct and beautiful as to deserve a place wherever there is the means of growing them. Amongst these may be reckoned the best small forms of the golden *G. chrysophylla*, the silver *G. tartarea*, *G. peruviana*, and *G. lanata*, all of which will now be commencing to grow, and must be supplied with heat and root moisture, but they should never be syringed overhead.

Platycterium.—*P. grande*, the finest of all this section, is deserving of cultivation, not only in the Fern house, properly so called, but anywhere where there is an intermediate temperature, with an end wall or a shady corner at which it can be placed. The only points of importance that I have found essential to a successful cultivation of this plant, are never allowing its roots to get too dry, but in giving water to them, to see that it does not get in any appreciable quantity to the layers of old dead shields that remain under the living ones, for if these are much wetted, it frequently happens that they communicate decay to the later formed living ones, laying

over and in contact with them before those last produced cover them; therefore be extremely careful that the young shields and also the fronds do not receive the slightest touch until they are perfectly developed. They are also liable to the attacks of Thrips, which directly disfigure them; shading them from the influence of the sun is at all times necessary. The distinct and handsome but smaller growing *P. Stemmaria* succeeds in a warm greenhouse under much the same conditions as those required by the common *Elk's Horn*, *P. alcinore*.

Flower Garden.

Auriculas.—Choice-named varieties of these should now be removed into the show house. Many of the pips are opening, but the best pips will not open without a little heat; they will do fairly well in frames, should the weather be mild; but dull, cloudy weather, and the temperature but little above the freezing point night and day, will be productive of mischief. It is astonishing to see how tenaciously some growers cling to old customs. Even the old-fashioned wooden shutters may yet be seen in some districts, and pots 6 in. or 7 in. in diameter with a *Smiling Beauty* or *Colonel Taylor* of small proportions pining away in the centre. The air of ordinary Auricula frames is too cold and damp for the most tender flowers. Placing mats on the frames at night and removing them in the morning is also troublesome. Alpine Auriculas are much more hardy than other kinds; even the finest varieties of them have stood out during the present winter in the open ground without injury, and, although behind those in frames, they look as well, and promise to produce flowers quite as freely. Their being later is all the better, as they will succeed those under glass. The Auricula will stand a zero temperature if the ground be dry, but stagnant water is fatal to it.

Carnations and Picotees.—The weather has been comparatively favourable for plants of these that have been potted into their flowering pots and placed out-of-doors. Although the east winds have been cold enough, there have been no heavy rains. See that the plants are quite secure, and if any of them show, by their foliage shrinking, that a wireworm is at the root, remove the plants and destroy the intruder. Now is a good time to sow seeds to produce strong flowering plants for next year. Sow in pots or pans, which may be placed either in a cold frame or on a gentle hotbed, on which the seeds will vegetate rather more freely. The frame might also be available for many other subjects, such as *Asters*, *Stocks*, *Zinnias*, *Rhodanthes*, and other half-tender annuals which may be sown at this time. See that the ground is in a friable state between rows of seedlings that are expected to bloom this year. Look for slugs and the leather-coated grub, which still does mischief if unchecked.

Dahlias.—Success on the exhibition table in reference to these can only be attained by good treatment now. See that they are not coddled too long in heat, nor exposed to cold east winds. The soil where the plants are to be placed should be turned over in fine weather, and a reserve of suitable compost may be prepared to place round the roots at planting out time. Supports for them should be prepared.

Gladioli.—The general collection of these may now be planted out, and of all the plants with which we have to deal the Gladioli, more than any other, requires a light, deep, rich, well-prepared soil. A change of stock is essential to continued success on the exhibition table or to produce the best flowers for other purposes. I have not yet found a better way to plant the corms than that of drawing drills, as for Peas, 18 in. apart. Plant them from 6 in. to 1 ft. apart in the rows, with a little sharp white sand under and over each corm, then fill up the drills with maiden loam well pulverised.

Phloxes in Pots.—If the frames are wanted for more tender subjects, these may well be placed out-of-doors in a sheltered situation. See that the plants are potted at once, if not already done.

Polyanthuses.—The beauty of these pretty spring flowers cannot fail to win its way to the hearts of all lovers of hardy plants. I well remember admiring a bed of them in Yorkshire, in which there were thousands of them in an out-of-the-way corner. They are of such a hardy nature that they do not refuse to grow even when partially shaded, or they will stand in open quarters just as well. The choice sorts in pots should now be crossed in order to produce seeds. Pin-eyed flowers, that is, those with the stigma protruding from the mouth of the corolla, produce the best seeds. The flowers of course must be well marked, and in all other respects what a Polyanthus ought to be. The plants have grown so much that it has been necessary to remove the pots to give them more room.—J. DOUGLAS.

Parks and Open Spaces.

Pruning.—Where pruning is necessary in consequence of shrubs having become overgrown, or from other causes, the general character of each must be preserved as far as possible. The beauty of shrubs, and also their utility, lies very much in their individuality; those whose habit is spreading should not be pruned to form close bushes,

and *vice versa*. The same applies to trees, and where it is necessary or desirable to prune with the object of preventing injury from high winds, my opinion is that it is much better to take out whole branches close to the stem than prune the branches themselves; this method, whilst thinning out the superabundant wood, does not destroy the character of the tree thus operated on. Speaking generally, however, trees should be artificially supported until they are capable of taking care of themselves, and I cannot help thinking that, so far as regards towns, those trees which have never been pruned are by far the handsomest.

Ivy and other Edgings.—These, when kept in good condition, are extremely effective, but the contrary is the case if neglected. Ivy and *Euonymus radicans* are useful town plants, and edgings of these from 1 ft. to 2 ft. in width are especially adapted for small open spaces, as, for instance, squares. The decaying shoots of each should be carefully pruned out and all dead foliage removed. Then the best and strongest of the young wood should be retained and regularly pegged down, putting in new plants where required. A light dressing of thoroughly decayed manure will also be found very beneficial.

Hedges.—These may with propriety be planted along the fences of public or private squares where it is not intended to use the banks amongst shrubs for flowers, and, without doubt, one of the very best shrubs for this purpose is Privet. A hedge of this neatly trimmed prevents the bare branches of larger shrubs from being seen.

Planting.—Although many perennials and annuals succeed fairly well in plantations which are scantily planted, yet I am of opinion that shrubs alone are best. Thick planting should characterise town gardens, in order that they may present as cheerful an appearance as possible during the dull season; indeed, I consider that a stock of shrubs in pots should be kept for filling all beds which are not devoted to the growth of Hyacinths and similar subjects. It is astonishing what might be done in this way at a trifling cost. In spite of difficulties there is still a goodly collection of trees and shrubs which withstand smoke tolerably well. If plantations be now lightly hoed or forked over a considerable amount of work will be saved hereafter.

Flower Beds.—Where it is intended to form new beds for flowers or fine foliaged plants, they should be prepared at once. The soil should be taken out to a depth of 2 ft. to 3 ft., a layer of brick rubbish from 6 in. to 1 ft. in thickness should then be placed in the bottom, and covered lightly with partly decayed manure, and filled up with a mixture of soil suitable for the plants intended to be used. Towards the middle of next month, it is probable that Hyacinths and some varieties of Tulips may require support; a method of doing this, which I have found very successful, is to have stiff wires, about 15 in. in length, bent round at one end to form an eye; these can be readily inserted into the ground. I pass the matting used for tying through the eye, and tie it just under the blooms, and as the stalk lengths the wires are lifted to the required height. Such supports are much neater than small sticks, and with a little trouble the wires might be made to clasp the stems, thus dispensing with the tying. Seeds of annuals, such as Mignonette, Beet, Iberis, Carduus, Larkspurs, Love-lies-bleeding, Prince's Feather, Sweet Peas, Linums, &c., may now be freely sown. As the majority of annuals are short-lived as regards flowers, the best plan to adopt when a succession is desired, is to sow at intervals of a fortnight, the main point tending to success being, that fine seeds are not buried too deeply nor sown too thickly.

Grass should be thoroughly freed of weeds, the growth of which will soon be rapid; roll and mow frequently. Also roll and weed roads and paths as often as may be necessary; tar-paved walks which show signs of deterioration should be painted over with tar, and covered thickly with fine sea shells, sand, or other similar materials. I am confident, from long experience, that this time of the year, provided the walks be dry, is preferable to the summer time for this work. The tar should be put on hot with long-handled brushes, and the shell or other materials should be spread over the surface, before the tar has set or become dry.—CHARLES DENNIS, *Southwark Park*.

Indoor Fruit Department.

Figs.—The earliest trees will now be approaching that critical stage when the fruit so mysteriously drops—an evil at the bottom of which is the introduction of cold currents of air. When any of our fruit has dropped, we have invariably observed it to be nearest to the ventilators; moreover, none of the second crop ever falls prematurely, the weather being then warmer, and the trees hardier, hence the advice which I would give, above all else, is to avoid cold currents of air, but to ventilate freely when the outside atmosphere is soft and balmy. As the fruit approaches maturity, discontinue syringing overhead, but keep up a goodly amount of moisture by repeatedly damping down both floors and borders. If manure water be occasionally sprinkled about, it will help to prevent red spider from gain-

ing a footing, and in other ways prove beneficial. I would again repeat the oft-reiterated injunction to keep the borders well watered, and always to use tepid water.

Vines.—At the present time, perhaps the most important matter connected with late Vines, which will now be starting into rapid growth, is to be certain that the borders have had a sufficiency of water to thoroughly moisten them throughout, a not very easy matter, taking into account the long time that water has had to be withheld from them, more particularly in cases where the Grapes were left to hang on the Vines; therefore, if any doubt exists as to deficiency on this score, fork down to the very bottom of the borders in one or two places that seem likely to be the driest, and if the soil on being pressed in the hand does not adhere, then water is still required. Mulch the borders thinly with stable litter, and keep up a humid temperature of 60° in the coldest weather, and whenever it is sunny give air early, and as carefully as if for early Vines, closing up by 2.30 with a renewed application of humidity, when, if 85° are reached, the Vines will revel in the extra warmth. Disbud as soon as the best "shows" can be discerned, leaving two shoots on each spur in the case of old Vines, but one only in the case of young and vigorous ones. Those in flower, Muscats more particularly, demand hourly attention to secure a good "set." If a circulation of warm, dry air, to disturb the pollen, could at all times be maintained, artificial fertilisation would be best left alone, but as this is impossible (at all events, in spring, when biting easterly winds are the rule), it is best to resort to artificial aid, which should be used when the highest temperature has been attained. The removal of surplus bunches before blossoming rather than after that period would tend to ensure a better "set." Lateral growths should be left intact till after the fruit is set. Grapes that are stoning should be kept at as equable a temperature as possible—say 65° at night and 75° by day, declining proportionately in exceptionally cold weather. A moderately humid, ammonia-charged atmosphere should still be maintained, but as the Grapes approach the saccharine state, moisture should be gradually withheld. Supply pot Vines that are bearing fall crops with an abundance of clear manure water, which, as a matter of course, should be of about the same temperature as that of the soil, and, where there is space for development, let the lateral growths extend without restraint.

Peaches and Nectarines.—In the earliest houses the fruit will now be stoning, and the trees will for a time require little attention beyond vigorously syringing them at least once daily to prevent the advent and spread of red spider. When the weather is mild and bright, the air moisture can scarcely be too great, and plenty of this is the best antidote for spider; but in cold, sunless weather an undue amount of atmospheric humidity would be as injurious as the evil it was intended to remedy, as it would probably tend to the production of mildew. Faint-heartedness as to pulling off all fruit not intended to mature should be overcome at once, as the energy wasted in maintaining such fruit, if utilised by early thinning, would be of immense benefit to the crop. Mid-season houses will now require to be finally disbudded, and if green or black fly has appeared, it will now be safe to fumigate, but it should be borne in mind that neither the young fruit nor foliage will yet stand a strong dose; it should, therefore, be done rather mildly and on two or three nights successively. The season is too far advanced for late houses to be longer retarded, so the moment the blossoms begin to open, if the weather be cold apply fire heat and air judiciously but regularly, in order to keep up a circulation of fresh air, and this with an occasional shake of the trellis will disperse the pollen, and no other aid will be required to obtain a free set. See that inside borders are well soaked through prior to closing up the house, and if fumigation be now effectually done, probably it will not be again required—at least that is my experience in the matter.

Melons.—It is now time to sow for the principal summer crop, and, as previously advised, the seeds should be sown singly or at most a couple in a 3-in. pot, or other, than no potting off or division be required, for, however carefully this may be done, a severe check is the result. When the early plants show fruit, select about four of the finest on each plant, and fertilise at one and the same time. Some varieties fail to swell off more than one or two fruits, and the reason frequently is because they have been set at different times, and the one that has got the lead has retained it. Till brighter weather arrives apply air moisture somewhat sparingly, and also keep the bed for the present rather dry than moist.—W. W.

Hardy Fruit.

The present, as far as fruit culture is concerned, is the most critical period of the whole year, for a single night's frost may do a large amount of injury; hence the importance of adopting preventive measures to ward off frost, let the cost of labour to do so be what it may. Evergreen boughs and Birch or Hazel spray, straw, or hay bands.

netting or canvas fixed to short poles, are all handy, effective protectors for walls that have not—as walls should have—proper movable blinds. Small bushes, lines of cordons, and espaliers, can be protected in the same way as wall fruits, the labour of doing so being by no means so formidable as one might imagine. Where there are movable curtains to walls they should be kept down during bright sunshine to retard the opening of the blossoms in hopes that the advanced season may bring freedom from frost when the flowers are fully expanded, and no matter what the weather may be, the coverings should be let down nightly, and on frosty mornings be allowed to remain down for some time after the sun shines, and during the prevalence of keen east or north-easterly winds they should also be left down. Although the weather has now become genial, the slow growth made by all kinds of fruit trees has been favourable to any planting or removal of trees that could not be done in the autumn, but it will be advisable now to defer any other such operations till next autumn, for, to say the least, the success of such late planting is rather a risky affair, success only being certain in the event of the springtime being showery, or through the pains taken to keep the roots of the trees moist by mulching and watering when such is required. Any further renovation of fruit tree borders still on hand should forthwith be completed. During the operation, all suckers or shoots that proceed from the stock should be cut off. I am at a loss to discover the cause, unless it be excess of moisture, but all fruit trees here during the last year have thrown up an unusually large amount of root suckers, Peaches especially being subject to it. We have had them all cut off, by working out the soil from about the uppermost roots, and have replaced it with fresh maiden loam, with which was intermixed a small proportion of wood ashes and bone dust, finishing with a rather thick layer of fresh stable litter. The importance of such surfacings cannot be over-estimated, and they are equally as valuable in the case of other fruits as in that of Peaches. A plot of ground should now be prepared, on which to plant out, as soon as sufficiently hardened, the earliest forced Strawberry plants. These, if the flowers be kept picked off, will produce early runners for another season's forcing, and some varieties—notably *Vicomtesse d'Haricourt* de Thury—will produce fine fruits in the autumn.—W. W.

Kitchen Garden.

Though prejudicial to vegetation, the cold north-easterly winds that have prevailed of late have been favorable to the advancement of work in this department, as without their drying effect, in many cases a suitable seed-bed could not have been obtained; as presumably such is now the fact, and that all that I term long season seeds have now been got in, the next operation will be planting out Cauliflowers, Lettuces, Cabbages, autumn-sown Onions, and the general stock of Potatoes. The earliest Potatoes will soon be above ground, and vigilance will be required to keep the soil well drawn over them till the haulm gets too high for this being done, when stable litter or Bracken shaken lightly over them will form an efficient protection against any ordinary frost. In dry weather the hoe is a great economiser of labour, and at this early season, though the weeds are barely discernible, it should be in full swing among all growing crops, such as Spinach, Cabbages, Broccoli, Lettuces, and Parsley, when it will both aid growth and destroy weeds. In the event of showery weather—for which this month is proverbial—a sharp look out for slugs will be requisite, or Cauliflowers, Lettuces, and similar plants will soon disappear. The best trap for these is bran put down in small heaps, of about a tablespoonful each, near the plants early in the morning and late at night. On this they will be found feeding, and can be destroyed. Lime, soot, and wood ashes all more or less deter them, but bran is the best remedy. It is yet rather soon to sow the general stock of Broccoli and Kale, not but what they would do best if sown now and grown on without check; but, as oftener than not they have to be planted on land that has been cropped with early Peas or Potatoes, the plants are apt to get stunted ere the ground is at liberty for them, so it is best to sow late; still the early kinds should now be sown, and also a few Savoy and Scotch Kale. We usually sow thinly in drills 1 ft. apart, and then no transplanting, other than the final one, is required.

Forcing Vegetables.—Potatoes, Carrots, and Radishes should be well aired; indeed, on bright days the lights should now be entirely off; more water will also be required, and a spindly growth of Carrots and Radishes prevented by timely thinning. French Beans in frames may be kept rather close till they begin to show flower, after which, air freely, support with Birch twigs, and water liberally; a check from want of water would be the precursor of red spider. All the *Seakale* intended to be forced this season should now be covered up. Asparagus will soon be had from the open air, and no more need now be forced. Rhubarb, too, in the open air is growing rapidly, and all

coverings may now be removed from this. Sow Celery, ridge Cucumbers, Vegetable Marrows, Tomatoes, Capsicums, and Sweet Basil.—W. W.

Extracts from my Diary, April 7 to April 12.

FLOWERS.—Shifting *Verbenas* out of cutting pots and putting them singly in 3 in. ones. Boxed *Pelargoniums* for bedding. Potting *Carnation Souvenir de la Malmaison*. Getting bedding plants out of Vineries into cold pits; also *Deutzias*, *Almonds*, &c., which have been forced. Pricking out *Lobelias* and *Pyrethrums* into boxes. Sowing another batch of *Primulas*. Shifting *Chrysanthemums* which have been struck from cuttings in pot Vinery into cold pits. **FRUIT.**—Tying Cucumbers and Melons. Top-dressing Vine border with fresh loam; also Melons. Tying Peaches and Nectarines; also Figs and young Vines. Pruning and nailing Morello Cherries. Planting out Strawberries that have been forced. **VEGETABLES.**—Finishing planting the main crop of Potatoes. Sowing French Beans in pots. Sowing main crops of Parsnips, Beetroot, Carrots, and Whitloof. Making new plantation of Mint. Sowing main crop of *Leamington*, *Autumn Giant*, *Self-protecting*, *Watts' Excelsoir*, and *Cattell's Eclipse* Broccoli; also main crops of Cabbages, Winter Greens, Brussels Sprouts, and Dwarf Uim Savoy.

TREES, SHRUBS & WOODLANDS.

THINNING PARK TIMBER.

INSTANCES of plantations having been neglected, or, to say the least, badly managed in the matter of timely thinning, may be seen almost everywhere. Few thin until irreparable damage is done, often not until a once promising plantation has become a tract of bare poles with a tuft of twigs on the top of each straggling up in search of sunlight. There are two chief objects for which timber may be grown, each requiring a special mode of management with a view to the best results in each case. The first is the management of timber with a view to profit; the second is its management with a view to ornament. Thinning in the first instance has to be performed very gradually, and must never be severe. The object being straight and clean trunks, sufficient room for a healthy head is all that is required without overcrowding, and the plantation should never be made so thin as to admit the prevailing winds cutting unduly through it; in short, the important matter of shelter cannot be forgotten where timber is grown for profit. But it is not with timber grown for profit that we wish at present to deal, but with ornamental or park trees as specimens; and with the production of really fine park trees thinning must be done in time and thoroughly. No one, even the most inexperienced, can fail to be struck by the beauty of trees standing out singly in a park, where they have had room to develop themselves throughout their existence without touch or shade of other trees, compared with trees of the same variety which have been only slightly overcrowded, perhaps leaning over to one side, or it may be branchless for the fourth of their height on one side. Trees of this latter sort are simply an eyesore, and it is for this reason more than any other, namely, the neglect of timely thinning, that many of our trees have a bad reputation as regards beauty. Everyone admires a well-grown Oak; or an Elm, dangerous though it be when old; or a Chestnut, which, as a flowering deciduous park tree is far before the Lime, which has long reigned as a favourite avenue tree, possibly because of its frequency on the Continent, but for which we have no special favour, but the contrary.

Again, no one will dispute the beauty of the Beech, even when its stem is bare to a great height; but for the Ash as an ornamental tree few will say a word. An old Ash, however, which has had room for fair development has a beauty peculiar to itself, altogether different from that of its stiff character when young; just as the stiff, arrow-shaped Scotch Pine gets flat and table-headed with age, so the Ash becomes pendulous when it is old enough to be a good park tree, but to arrive at this stage and to be really an ornamental object it must never have been spoiled by contact with other trees. The Birch is a tree neglected on account of a supposed want of beauty, but when old it is one of the most graceful of trees, changing its stiff, upright growth to just the reverse. It cannot be included amongst our largest park trees as single specimens, but in groups wide apart it is quite distinct and beautiful, its beauty being enhanced by its silvery-white bole shining through the

branches. It is one of those trees which quickly get spoiled if thinning has been neglected. Its branches are slender and impatient of shade, the bottom branches quickly dying off, leaving the tree a bare pole. Where specimen trees are the object, whether in groups or plantations, or where single specimens are being nursed for a time with a surrounding of minor trees, thinning must be done without delay. When the side branches begin to come in contact at the tips in some instances, as in the case of trees which have a pyramidal habit, this is even too late. We may refer to the Turkey Oak as an example of a tree which should be thinned sooner than the English Oak, as being much more liable to be spoiled from overcrowding. We have often heard the remark, "Oh! they have still some room; let them grow a little longer;" and so irresolution ends in mischief.

A great mistake is often committed by planting large trees, such as the Lime and Elm, too closely together to form groups. In a young state, what appears to be ample room is found, when the trees have only half grown, to be quite inadequate, and thinning becomes a difficulty; if it be done at all, the symmetry of the group will be spoiled, and, if left unthinned, the trees do, of course, grow into what looks a compact group from a distance; but the outside trees must of necessity become one-sided and lean outwards, while the inside trees become bare poles with a few green twigs at the very summits. The permanent trees in a plantation, if there be any hope of their ever attaining to specimen size, should never be planted nearer than 54 ft.; that space is even too little for Oaks or Beeches. I am acquainted with a plantation formed by one of our ablest landscape gardeners where the permanent trees—Cedars of Lebanon—are planted 150 ft. apart, the intermediate spaces being filled in with miscellaneous trees, to be entirely thinned out as growth progresses. Where miscellaneous plantations have been made without any preconceived plan as to thinning, or what particular tree or trees were ultimately to be permanent, it is best in the first place to select those sorts for permanent trees which seem best to suit the soil and locality, as, for instance, the Beech will be found to succeed perfectly where the Lime and Elm will not do well; the Lime will grow where the Oak will not, and the Sycamore or Norway Maple where none of these will be successful. Fortunately, the Horse Chestnut is not fastidious as to soil, which gives this fine park tree always a chance among the many. The most healthy trees in a given locality will be, as a rule, the best shaped ones, and the shape of a tree will always count a few points in its favour when it comes to the question of selection for the axe. The badly shaped tree will have to go away, provided the space left vacant by its removal is not too great, for better have a badly-shaped tree than no tree, it being only a question of time for a tree to ultimately balance itself if not hopelessly spoiled from long contact with others. Thinning may yet go on for a week or two before trees get overloaded with foliage; indeed, I have no hesitation in saying that it is never too late to thin. We have thinned young plantations all summer, or where it is absolutely necessary to relieve fine trees from being spoiled. The value of the fallen timber should never once be thought of where the well-being of the trees, left from an ornamental point, is concerned.

G. D.

Pinus insignis.—A very fine example of this handsome Californian Conifer is at present growing in the gardens at Claremont, the residence of Mr. Stephen Warren, distant about three miles from the Waltham Station of the Great Eastern Railway. The tree, which stands on the lawn, is about 40 ft. high, and beautifully furnished with branches to the ground, forming a fine symmetrical specimen, remarkable for its deep grass-green, dense, and massive appearance. This tree has apparently withstood without injury the severe and prolonged cold of the past winter. Smaller plants of this Pine, in the same garden and in other places in this neighbourhood, have likewise come through the winter unscathed, a fact which says much for the value of a dry October, as experienced last year, for ripening the wood of our more tender trees and shrubs.—ARTHUR W. PAUL, *Waltham Cross*.

Narcissus Bulbocodium.—This is a most useful Daffodil for growing in pots for the embellishment of the conservatory. We have some plants of it growing in 6-in. pots with from twenty to thirty blooms on them.—J. C., *Farnborough*.

CALCULATING THE HEIGHT OF A TREE.

WHEN the height of a tree can be ascertained by actual measurement, it is always best to determine it in that way, but it rarely happens, if the tree is above 20 ft. high, that this method is available without risk of injury to the tree. In most cases, the height of a tree of remarkable size has to be determined by calculation, and if the ground be clear and level around it, this calculation is very easy and requires no greater knowledge of arithmetic than the rule-of-three or simple proportion. The principle upon which all sums in simple proportion are worked is that of having three amounts given from which we have to obtain a fourth, which is the answer. We all know that the answer is certain to be right if the sum be correctly done; but there is another "if" which we must not overlook. The sum may be correctly worked, but the height of the tree will not be right if there be any mistake in either of the three amounts given to you. In order to be accurate in the determination of the height of a tree, it is necessary to be fully alive to the different ways in which mistakes may arise in one or all of the three measurements from which the height has to be calculated. There is only one way of obtaining this knowledge, and that is by clearly understanding the principle upon which the calculation is worked. This we will endeavour to explain in language as simple as possible, aided by a few engravings.

Fig. 1.

With a 2-ft. ruler and a lead pencil draw a straight line as has been done at A B C in fig. 1; let this line be 12 in. long, and make a mark at B half-way along; the point B will then be 6 in. from A and 6 in. from C. Now draw an upright line from B to D, and make this line of any length, say 5 in. long. If you have done this correctly, the distance from A to D (along the dotted line) will be the same as the distance from C to D; but if the length of the two dotted lines be not exactly the same, the line B D must be wrongly drawn; in other words it is not upright.

Fig. 2.

A ready way of drawing one line upright to another is that which carpenters call the "3, 4, 5" method, and this is shown in fig. 2. Draw a line J to L, and make it 4 in. long; cut two strips of stiff paper, one 3 in. the other 5 in. long; lay one end of one strip at J, and one end of the other strip at L, and you will find that you can make the other ends of the strips meet at N. If a line be now drawn from N to L, it must be upright on the line J L.

We will next suppose that we have, in fig. 3, the line L M drawn about upright to J L, and that we wish to prove whether it is really upright or not. In order to determine this, the line J L must be halved, and each half halved again, whereby we get it divided into four equal parts. Now carry on the line L M towards N until the distance from L to N is equal to three

of these parts. Lastly, measure the distance from J to N , and if that distance be equal to five of those parts then the line LM is perfectly upright.

Fig. 3.

Having thus, as we hope, made it clear what is meant by an upright line, how to draw one correctly, and how to ascertain whether a line is upright or not, we propose in future to call every upright line a perpendicular, that being the word commonly used by those who have to deal with heights and their measurements. They also call the line upon which a perpendicular is drawn the base line.

Fig. 4.

Upon fig. 4 is a line BC , which is perpendicular to AB . If the dotted line from A to C be carried on in the direction of E , and if the base line AB be also carried on in the direction of E , and if another perpendicular line be drawn anywhere along the line ABD , as, for instance, at D , the length of each perpendicular line will be in proportion to the length of its own base line; in other words, the base line AB is to its perpendicular BC as the base line AD is to its perpendicular DE . In the figure AB is 10 and BC 6; if, therefore, AD is twice 10, DE must be twice 6, and so on.

Fig. 5.

Let us now go a step further and look at fig. 5. It is a repetition of fig. 4, with an additional line CH , the distance from D to H being the same as from B to C . We already know that as AB is to BC , so is AD to DE , and we need not there-

fore stay to prove, what must be evident at a glance, that the same proportion must also exist between the base line CH and the perpendicular HE . If any one should doubt it he has only

Fig. 6.

to turn fig. 5 on one side, as at fig. 6, whereby base lines and perpendiculars change their names, and he will see that base line EH is to perpendicular HC , as ED is to DA , or as CB is to BA .

Fig. 7.

In fig. 7 will be found a third perpendicular PQ , of course bearing the same proportionate length to that of its base line AB as the others bear. It will be unnecessary here to go over the same ground again in order to prove that we are correct in asserting that the base line CP is to the perpendicular PQ as the base AD is to the perpendicular DE .

Let us now proceed to apply this knowledge of proportions to the practical use which is our object in view, and in order to keep to simplicity as far as possible in our explanations, we will retain the same letters in our future illustrations as heretofore used. Provide two light poles, each with a pointed end, and of such lengths that when stuck firmly into the ground one shall be just 5 ft. high and the other 10 ft. high. Another plan is to fasten each pole into a square piece of thick plank in which it stands upright. In either case, the poles when used must be of the proper height and be placed perfectly upright, and this must be ascertained by a string and weight. In fig. 8, the 5-ft. pole BC is 6 ft. away from the 10 ft. pole DE , and upon looking from the top of the shorter pole to the top of the longer one, we see the top of the tree DE in the distance. Now the proportion which we have to work out is this: as CP is to PQ , so is CA to AE ; we can measure the first three of these terms in the proportion and from them calculate the last term. The first term CP is the distance between the two poles, which is the same as BO , or 6 ft. The second term PQ is the difference between the heights of the two poles, namely 5 ft. The third term CA is the same as BD , being the distance of the shorter pole from the tree trunk, which by

and lurid purple powerfully aromatic blossoms, borne singly on short stalks at the extremity of the branches, which, as well as the roots, have, when bruised, a very decided smell of camphor. The blossoms, when crushed, exhale more or less a fragrance of Strawberries, or, according to some, of ripe Quinces or Apples. In the typical plant, which in a state of nature is found in rich soil on hillsides in Virginia and southward, and flowers from May until August, the leaves are oval, and softly downy beneath; fruits are but rarely developed. Under favourable conditions this species will attain a height of 6 ft. or 8 ft. Several varieties, some of which have at various times been regarded as species by different botanists, are to be seen in botanical and other establishments. The principal of these are:—

OVATUS, a form with roundish-ovate leaves.

OBLONGUS, a variety with oblong leaves.

LONGIFOLIUS, in which the foliage is much longer than in the type.

MICROPHYLLUS, in which, as the name implies, the leaves are much smaller.

NANUS, a compact-growing dwarf variety.

INDORUS, a sport with flowers almost or quite scentless.

There is also a form with variegated foliage, known as *VARIEGATUS*; and another, *ASPENIFOLIUS*, with cut leaves.

The **Glabrous-leaved Calycanthus** (*C. lavigatus*) is found on the mountains of Pennsylvania, Virginia, and Carolina, and flowers from May to August. It has rather wrinkled, oblong or ovate, gradually taper-pointed leaves, rough to the touch on the upper surface, and smooth and green on the under. The blossoms, which are hardly sweet-scented, are of nearly the same lurid purple colour as those of the preceding kind. *C. ferax* and *C. pennsylvanicus* are names under which this is sometimes found in both books and gardens.

The **Glaucous-leaved Calycanthus** (*C. glaucus*).—The large, conspicuously taper-pointed, somewhat lance-shaped leaves of this kind distinguish it well from the foregoing; they are flat, green above, and of a decidedly whitish-grey tinge beneath. The almost scentless blossoms are less deep in colour than those of the Carolina Allspice, from which they differ in being frequently fertile. It is found on the mountains in Virginia and southward. In some books it is described as *C. fertilis*.

The **Western Calycanthus** (*C. occidentalis*) is a much larger shrub than, and totally different in habit and general appearance from, the others. It is handsome in growth and foliage, and especially so in the large size and bright colour of its blossoms, which are 3 in. or more in diameter, and of a somewhat bright purplish-red colour. It was sent by David Douglas from California to the Royal Horticultural Society's Gardens in 1831. It is perfectly hardy, but a warm, sunny spot or a wall singularly favours the ripening of its wood and, consequently, the production of its beautiful flowers, which, however, totally lack the delicate scent peculiar to some of the kinds, or, to speak more correctly, are destitute of any scent whatever. The leaves are large, 5 in. or 6 in. or even more in length, heart-shaped at the base and somewhat taper-pointed, shining green on both upper and under surfaces. This is known in some gardens as *C. macrophyllus*, and flowers from the end of August to October. G.

WOODLAND WORK FOR APRIL.

WHATEVER spaces have to be filled up in woodlands should now be furnished as quickly as possible, both as regards deciduous and coniferous trees. The main point to attend to now is quick removal, allowing no plants to remain out of the ground longer than is absolutely necessary. The grafting of trees may still be continued, the Fulham and Lucombe upon the common Oak and the rare and variegated kinds of Maple upon the Norway Maple and the Sycamore. Dry and frosty weather in April is a good time for removing the dead branches of the Larch, Spruce, and Silver Fir. The operation is best performed by dealing them a smart blow with a heavy stick or mallet, which loosens and withdraws the bolt-like insertions so injurious to the converted timber. The pruning and trimming of all evergreen shrubs and hedges should be finished up and large plants brought from the nursery to fill up gaps. Hollies and Yews, the Hemlock Spruce, Portugal and common Laurel, and the Box may now be safely removed as strong plants 3 ft. high, but they should have been previously transplanted in the nursery so as to have secured for them plenty of bushy, fibrous roots. In removing at this season of the year large plants which stand singly in a dry soil a good watering round the roots, followed by a thorough ramming or beating of the soil, will enable the transplant to remove them with a solid ball. This is a favourable time for sowing Grass seeds upon wood rides or for game cover in open corners of the woodlands. For rides I have found the following mixture suitable:—Timothy, tall Fescue, Meadow Foxtail, and hard Fescue, 2 lb. of each; rough Cockfoot and smooth-stalked Meadow, 3 lb. of each; sweet-scented

Vernal and rough-stalked Meadow, 4 lb. of each; wood Meadow Grass, 7 lb. Prepare the ground and sow Whin or Furze seeds either for hedges or for game covert. Hedges of this plant should not be trimmed until towards the end of June. Also plant cuttings of Osiers for the use of the basket maker. Choose land near a stream, so that water may be admitted into the open intermediate ditches or shut out at pleasure by means of sluices. Cuttings of 12 in. or 14 in. long, from branches of two years' growth, may be planted in rows from 18 in. to 3 ft. apart, and from 18 in. to 2 ft. between the cuttings, according to the growths of the various kinds and the ages at which they are intended to be cut. These cuttings should be inserted about two-thirds of their length. The ground intended for Osiers should be well trenched, liberally manured, and thoroughly cleaned. If the weather is mild seedling evergreens should be lifted by the middle of the month, never taking up more than can be planted again the same day. Scotch Pines (two years' seedlings) may be planted in rows 12 in. apart and 3 in. between the plants; the land should be in good condition, in which case, at the end of another year, they will be fit for planting out permanently. Strong Spruces of two years old or weaker ones of three years may also be removed. If planted in a rich, humid soil, they will make great progress. If intended to remain two years in the lines give them spaces of 12 in. by 6 in.; also transplant two-year Silver Firs—these will require more space than the Spruces. The Pinaster and Stone Pines should be planted out in lines as one-year seedlings, otherwise they become too tall and slender; sandy loam suits them well. Considerable care is required in lifting the Stone Pine on account of the length of its roots. Two-year seedling Hollies may be planted 5 in. or 6 in. apart, in situations shaded from the midday sun; these, as well as the Yew, flourish in a rich sandy soil. The cones of Firs and Pines, where still unopened, should now be placed upon a hair sieve on a kiln and subjected to a heat of not more than 112° Fahr.; if necessary, they may afterwards be threshed and then sifted. The Silver Fir, Balm of Gilead Fir, and Weymouth Pine yield their seeds with very little trouble, but the Larch, Scotch Pine, and Spruce generally require more attention. Finish sowing all seeds of the Coniferous kinds, and protect from frosts beds of young plants, particularly in situations where the morning sun may strike them while in a frozen state. Mark as soon as possible all Oaks intended to be felled this season, and make preparations for the bark stripping, of which I will give some account later on in the month. A. J. BURROWS.

Oak Timber.—Much of the oldest Oak Timber in this country is not of the same kind as that now in use. What we call Oak timber now is the wood of the *Quercus pedunculata*. This has its fruit stalked and its leaves sessile. The other Oak, the *Quercus sessiliflora*, has its fruit sessile and its leaves stalked. This latter is the Oak which furnished timber to some of our oldest buildings—to St. Alban's Abbey and to Westminster Hall. The old wood is so unlike our modern Oak timber, in the absence or indistinctness of the silver grain, that it was long considered to be Chestnut.

Convolvulus Cneorum.—The fine specimen of this highly ornamental shrub, which was the source of so much attraction at Kew during the last and previous seasons, has unhappily fallen a victim to the cold of last winter. A considerable number of other South European shrubs have unfortunately also shared the same fate, a fact which a glance at the walls and arboretum at Kew will fully confirm. As, however, it is of tolerably rapid growth, those who have sustained the loss should not be discouraged, but should plant again. —V.

Choisya ternata.—It is gratifying to find that this handsome Mexican shrub has withstood the exceptionally severe winter through which we have passed with only the protection of a wall. It cannot be too highly recommended for general culture, as even when not in flower it is a fine evergreen. An idea of its beauty when in bloom may be gleaned from the coloured illustration of it which appeared in THE GARDEN, Vol. XII., p. 232.—W.

Straightening Trees.—One may not be able to quite straighten trees that are crooked, but, nevertheless, their appearance may be greatly improved by the following operation:—Make two or three longitudinal incisions on the inner side of the bend, and repeat this several times during the summer; it will increase the formation of wood on that side. I have seen this result with trees from 2 in. to 4 in. in diameter, the trees being left almost straight.—“Cultivator.”

Clintias carneus.—So far as I am able to see, this is the only plant killed in our garden by the late severe winter. It was growing against a south wall, and was never protected. Plants of it in a cool greenhouse will soon be in great beauty, and, with protection of this kind, few flowers are more showy at this season of the year. —CAMBRIAN.

WOODLAND GARDENING.

THIS kind of gardening is now becoming interesting. Many subjects that have long lain dormant are now bursting forth into leaf and flower from under the covering of dry leaves or decayed stalks, which it is always advisable to allow such subjects as deciduous Ferns to bear, as they not only protect the crowns but preserve the roots from frost. Many plants found to winter quite safely under such conditions suffer severely in bare flower garden beds. Our woodland garden here is a dell overhung on the north by a steep, almost precipitous bank that shelters the occupants from the cutting blasts that blow from that quarter. Winding flights of steps roughly cut in the bank lead down into it from the dressed grounds, and here, under the shade of overhanging trees, on which Ivy, Mistletoe, and wild Clematis are allowed to ramble at will, may be found an agreeable resort at all seasons of the year. Clumps or irregularly formed beds of flowering, deciduous, or evergreen shrubs, are dotted about without formal design, and old, Ivy-clad stumps of trees form a rookery nearly hid from view by a covering of hardy Ferns, Cotoneasters, Periwinkles, and Eucnymus. At the present time Primroses quite carpet the turf with an endless variety of colours, the remnant of the named varieties being planted here indiscriminately after the beds in the flower garden are planted, and, as they seed freely, the result is a mixture of all shades of colour. Polyantheses, Oxlips, and Cowslips are just coming into flower, while Snowdrops and Aconites are getting over. Crocuses of many kinds are, however, abundant; here, too, Narcissi, Jonquils, and Daffodils find a congenial home, and wood Anemones and single Violets flourish both on bank and dell. The only drawback is that mice eat the Crocus bulbs, especially such as are freshly planted. The beauty of a wild or woodland garden depends very much on the position which it occupies; anyone having an old quarry or gravel pit, or any kind of irregular surface may soon convert it into a pleasant and interesting resort by adding from time to time hardy plants that will never fail to produce effective flowers. In level districts a worn out orchard might be utilised in a most interesting way; the old stumps might be made to support climbing plants, and by letting the hedgerow grow wild, a screen would be produced that would afford shelter, and that would at the same time shut out from view other portions of the ground. J. GROOM.

Ice Storing.—"C." (p. 261) persistently endeavours to charge me with what I never uttered. I am made to advocate a thick column of straw. This is a misrepresentation; I never used the word "thick." My central column of straw was in bulk little more than that of a draining pipe, and as for its being a channel for heat, where is the heat to come from in a vault wholly underground? My sketch of an ice well or cellar, as regards shape, was merely imaginary, or, at least, not absolutely correct, and was only intended to show the method of applying the drainage; a scale or dimensions was never meant. I have said, and still maintain, that the best place for storing ice is a vault or cellar wholly underground, and such places may be three or four times as wide as high, provided they be deep enough from the effect of vertical heat. I will also mention that it is infinitely preferable to take the ice from an aperture at the top of the cellar the same as water is drawn from a well, and not from a door or aperture at the side, which is about the best method that could be devised for admitting heat and air to the cone of ice. Now, let me answer "C.'s" questions briefly. I am described as furnishing an argument against myself concerning central drainage. When I said that "water poured on the top will almost be immediately congealed and will never scarcely percolate to the bottom," I stated what was true, but "C." should remember this was during frost; and now for another question. "How do I reconcile this statement with having seen ice with water standing on the top as in a bowl?" Let me here remind "C." that this was at melting time; certainly not simultaneously. "C." says "he never witnessed such a phenomenon;" probably not, nor yet others who stack ice in the shape of Cleopatra's Needle. But I must again "theoretically and practically" assert that a mass of ice in a vault of whatever shape, if broader than high when the opening is at top, has a tendency to only melt at the top, and to become dish or bowl-shaped under the opening, and that the sides of such places, being farther from air and solar influence, are as cool as the centre, and it is a totally different circumstance from an upright body of ice, having a door at the side to let in heat and with a side wind.—T. WILLIAMS, Ormskirck.

NOTES FROM KEW.

Hardy Plants.—Each successive week at this season of the year brings to our notice fresh objects of interest, and amongst the most noteworthy now in flower is the Persian Iris (*Xiphium persicum*), introduced as long ago as 1627. Though not so beautiful as the Notted Iris (*X. reticulatum*), it presents a more striking contrast in colour, the three spreading falls being creamy-white heavily blotched with the deepest purple at the tips and copiously spotted on the lower half relieved by the bright orange crest, and the inner sides of a delicate porcelain-blue tint; the upright petals or standards are reduced to mere scales. It moreover yields an agreeable odour. Like its congeners, it is perfectly amenable to pot culture, and it will also succeed in Hyacinth glasses. Another charming bulbous plant is Nuttall's Erythronium (*E. Nuttallianum*), a yellow-flowered kind, much in the way of *E. americanum*, with similar bright yellow blossoms, having reflexed petals and reddish stamens, but lacking the marbled foliage of the latter kind, and it is technically distinguished by the absence of the very small ear-like processes at the base of the petals, as seen in all the other species. That beautiful old favourite the Dog's-tooth Violet (*Erythronium Dens-canis*) should be accommodated in every flower border, as it is amongst the earliest of spring flowers. Amongst Drabas, which are pretty rock plants, belonging to the Crucifer family, the best is *D. brunifolia*, a rather scarce kind, and a native of the Caucasus. It forms dense, cushion-like, bright green tufts, studded profusely with small golden blossoms. The yellow Alpine Whittow Grass (*D. aizoides*), one of our rarest wild flowers, is remarkable for its bright yellow blossoms and glossy leaves, margined with hairs produced in rosette-like tufts. *D. cuspidata* much resembles the last, but is smaller and looser in habit. Another desirable Crucifer is the many-leaved Coral-root (*Dentaria polyphylla*), which inhabits various parts of Central Europe. It grows about 6 in. high, and has leaves arranged in threes, each divided into four pairs of leaflets. The flowers, which are large and creamy white, are produced in many flowered terminal clusters. Turning to the Borage family, which yields so many fine border flowers, we notice the early flowering Oriental Borage (*Borago orientalis*), a kind with a spreading habit and ample foliage, producing abundance of clusters of violet-coloured blossoms, the petals of which reflex as in a Cyclamen. The majority of the kinds of Comfrey are gigantic in stature and coarse in habit, but the Iberian Comfrey (*Symphytum ibericum*) is interesting on account of its growing only a few inches high; it has small, deep green, heart-shaped leaves and drooping clusters of yellow blossoms, which are about the size and form of those of *Oenothera lutea*, but are red before expansion. This is an excellent plant for a rockery or front row of an ordinary border, as it apparently thrives equally well in both situations. Some of the charming alpine Primulas are finely in flower, and amongst them the Fairy Primrose (*P. minima*), one of the smallest of the family. It has rosettes of small wedge-shaped leaves, beset with sharp teeth at the tips. The flowers are large for the size of the plant, being nearly 1 in. across, and rose-coloured. It inhabits the mountains of South Europe. The Entire-leaved kind (*P. integrifolia*) is another gem; it has glossy leaves, and white-eyed rosy blossoms as large as a shilling. *P. Dinyana* is another diminutive species; it has viscid, slightly-toothed leaves, and rich purple blossoms borne in clusters on short stems. The Himalayan *P. denticulata*, with its numerous shades of purple flowers, is also well represented, and some appear to be distinct enough to merit varietal names.

Hardy Shrubs.—Both walls and shrubberies are enlivened just now by the bright golden blossoms of the Drooping Forsythia (*F. suspensa*), a Chinese shrub of singular beauty. Its slender, gracefully drooping branches are covered with flowers, which last in good condition for a considerable time. Though it is perfectly hardy and succeeds well in a shrubbery, it is seen to best advantage when planted against a wall. Not so, however, *F. viridissima*, which is also in flower; its habit is stiff and formal, and therefore it is best adapted for forming isolated specimens, or interspersed with other shrubs. *Cornus Mas*, a European shrub, covered with heads of small yellow blossoms, is also attractive, and so are also the several varieties of that most desirable shrub the Mezerium (*Daphne Mezereum*). Standish's Honeysuckle (*Lonicera Standishi*) is very sweet scented, and on that account, as well as because of its early flowering, it merits a place amongst hardy shrubs.

Stove Plants.—By far the most attractive object in the Palm House is the East Indian Asoca (*Jonesia Asoca*), a shrub belonging to the Pea family. It grows several feet high, has handsome pinnate foliage, and possesses the peculiarity of producing its clusters of blossoms, which are orange when first expanded, changing to bright scarlet, both on the naked branches and young shoots. The Scarlet Brownea (*B. coccinea*) is another striking plant; it bears dense clusters of rich scarlet flowers in the same remarkable manner as the

Jonesia. It inhabits various parts of the West Indies. *Sinningia Youngiana*, a Gesneraceous plant, very similar and nearly related to the ordinary *Gloxinia*, is a very handsome stove plant, with large, ovate leaves and rich purple blossoms. It is said to be a hybrid between *Ligeria speciosa* and *Sinningia velutina*. Amongst the Bromeliads, Libon's *Bilbergia* (B. Liboniana) well merits a place in every stove. It is of medium size, with Pine-apple-like foliage, from which arise several flower stems bearing long tubular blossoms with scarlet calyces, and corolla white in the lower half, and deepening to rich purple at the tips. It was discovered in the environs of Rio de Janeiro several years ago by M. Libon. *Alpinia bracteata* is a handsome member of a much neglected family formerly known as *Scitamineæ*. It grows about 5 ft. high, has broad, Maranta-like foliage, and produces terminal spikes of rather large white blossoms heavily pencilled inside with cinnamon red. It is of Chinese origin, and an old inhabitant of stoves.

Greenhouse Plants.—Amongst these, one of the most interesting now in flower is the little trailing *Sarmienta* (S. repens). It has numerous slender, trailing branches, with opposite, small, roundish leaves, slightly toothed at the tips, and from the axils of which are produced bright red blossoms, about 1 in. long, urn-shaped, with protruding, yellow-tipped stamens, the whole plant reminding one of *Mitrasia coccinea*. It is admirably adapted for growing in a suspended basket or pot, and, being a native of the cool districts of Chili, it should be grown in a cool, moist greenhouse or frame partially shaded. The *Asarum*-like *Heterotropa* (H. asaroides) is a curious Japanese plant, and a member of the *Aristolochia* family. In foliage it strikingly resembles *Cyclamen europæum*, having the same heart-shaped leaves and beautiful variegation. The flowers are hidden by the foliage, but, as they are more singular than beautiful, that is not so much to be regretted. Some of the Cape Irids are very useful decorative bulbous plants. The old *Synnotia bicolor* has Iris-like foliage, from which arise stems bearing flowers of a creamy-white, the lower petal being purple with a grooved crest of yellow. *Sparaxis grandiflora* and *tricolor* are also desirable, the former producing large white blossoms striped with purple on the outside; the latter flowers with almost every intermediate shade from bright red to orange. *Styphelia tubiflora* is a very ornamental, erect-branching plant, very similar to an *Epacris*. Its narrow, tubular flowers are of a rich carmine tint, the petals being beautifully fringed with the same coloured hairs. It is a native of New South Wales. W.

NOTES OF THE WEEK.

Rhododendron Aucklandi.—In a rocky corner of my winter garden a little tree of this *Rhododendron* is now bearing seventy-three trusses of flowers, each truss containing from seven to nine large blossoms. I cannot understand why this most beautiful species is so seldom seen in cultivation. When well treated and fully established it is very free flowering, and its waxy-white blossoms, which are slightly veined with rose, are deliciously perfumed.—O. F., Augsburg, Bavaria.

Seedling Hepaticas.—We have received from Messrs. Rodger, McClelland & Co., of Newry, blooms of a seedling form of *Hepatica triloba rubra* called *superba*. It is larger than the ordinary kind, has rounder petals, and is also different from the type in colour, which is of a bright and beautiful shade of rose.

Brownea grandiceps.—This is said, by the "Irish Farmers' Gazette," to be now in full flower in the large stove conservatory at Glasnevin, and to be a sight worth seeing. It is furnished with upwards of fifty of its gorgeous flower-heads, which, set off to advantage by the dark pinnate foliage, are most effective. In an intermediate house adjoining, *Solandra grandiflora*, which covers a considerable portion of the roof, has been for weeks and is still very striking and noteworthy, producing in profusion its great trumpet-shaped white flowers, which in size and form much resemble those of the white *Brugmansia*, but instead of hanging perpendicularly, like those of the latter, they stand out horizontally from the stem.

Orchids at Holloway.—Now when the stately species of East Indian Orchids do not receive so much attention as they once did and still deserve, it is refreshing to meet with a thoroughly well-grown collection, such as that in the Victoria Nursery, Holloway. *Vandas* especially, which are too often found with bare stems, may be seen here in quantity, with arched leaves perfect down to the pots; the different forms of *V. suavis* and *V. tricolor* alone are pushing up some fifty or sixty flower-spikes, several of which are already beautifully in bloom; one in particular, *V. tricolor formosa*, has petals and sepals in the case of newly-formed expanded flowers, quite flat and heavily spotted and diffused on the margin with deep

purple. Here also is an immense mass of the scarce *Odontoglossum Londeborghianum* some 3 ft. by 2½ ft. across, newly imported but in excellent condition. From what has been seen of this *Odontoglossum* in the shape of the few plants which have bloomed in this country, it is a magnificent addition to this already rich genus. If, as has already been stated, it comes from the same district as *O. citreum*, it may be expected to thrive under like conditions, i.e., not too hot but still enjoying more warmth than the generality of *Odontoglossums*.—P. G.

Hardiness of *Habranthus pratensis*.—This is now coming up strongly in my garden, having stood through the winter without any protection. This fine plant may therefore be considered perfectly hardy, as the frost must have penetrated far below the position of the bulbs.—J. G. N.

Orchids at St. John's Wood.—The following Orchids are now in flower in Mr. F. A. Philbrick's collection at St. John's Wood, viz.:—

<i>Angræcum sesquipedale</i>	<i>Dendrobium lituiflorum</i>	<i>Odontoglossum Rossi-</i>
<i>Ada aurantiaca</i>	<i>Devonianum</i>	<i>majus</i>
<i>Celoglyne cristata</i>	<i>Cochlidium</i>	<i>Cervantesi</i>
<i>Catt. v. Harrisoniæ</i>	<i>Findleyanum</i>	<i>Cervantesi decorum</i>
<i>Trichia</i>	<i>crepidatum</i>	<i>Oncidium cucullatum</i>
<i>citrina</i>	<i>Pierardi</i>	<i>janicolum</i>
<i>Cypripedium villosum</i>	<i>Lælia superbiens</i>	<i>Phalænopsis Casta-</i>
<i>Dayanum</i>	<i>anceps</i>	<i>anabilis</i>
<i>Argus</i>	<i>Lycaste Skinneri</i>	<i>grandiflora</i>
<i>barbatum</i>	<i>Masdevallia ignea</i>	<i>Schilleriana</i>
<i>biflorum</i>	<i>Odontoglossum Alexan-</i>	<i>Sophranitis grandiflora</i>
<i>Dryanum</i>	<i>drae</i>	<i>Vanda suavis Veitchi</i>
<i>Dendrobium nobile</i> , several varieties	<i>pulchellum majus</i>	<i>suavis Kollasconi</i>
<i>elegans</i>	<i>roseum</i>	<i>tricolor superba</i>
<i>Wardianum</i>	<i>Phalænopsis</i>	<i>tricolor insignis</i>
<i>crassinode</i>	<i>cirrhosum</i>	<i>gigantea</i>
<i>crassinode</i>	<i>Pescatorei</i>	<i>cæulescens</i>
<i>Barberi-</i>	<i>nebulosum</i>	
<i>anum</i>	<i>nebulosum pardinum</i>	
<i>Freemant</i>		

Pansies.—Notwithstanding the severity of the weather, until within the last few days Pansies are beautifully in flower in several places. We have just seen some fine blooms of both fancy and other kinds from Mr. Hooper's garden, at Widcombe Hill, Bath. They were named kinds, the best of which were John Darke, J. T. D. Llewellyn, Rev. J. Phelps, all rich dark shades of red; Sir William Wallace, yellow blotched with maroon; G. F. Wilson, a finely formed fancy kind; White Clipper, white blotched with bluish-purple; and William Goodchild, pale blue blotched with black. Several others were also equally good.

Hardy Plants in Bloom in the Newton Nurseries, Chester.—Notwithstanding the severity of the winter, and the bitter east winds which we have experienced of late, we have a fair amount of Alpines and the earlier bulbous plants producing quantities of bloom. A fine bed of *Bulbocodium vernum* has been producing its lovely purple flowers for the past three weeks, also a few plants of its variegated variety. Crocuses are nearly out of flower; a few of the best are Imperati, Sieberi, biflorum, Auberti, and asiaticum. Some half-dozen beds of the Dog's-tooth Violet (*Erythronium Densa-canis*) will, with the aid of a few sunny days, be a mass of rosy-lilac flowers. *E. Densa-canis* album is now in flower, and some plants of *E. giganteum* are throwing up some fine spikes. Despite the cold, *Iris reticulata* has never ceased to produce its lovely violet-scented blooms. *Saxifraga oppositifolia* and its varieties are also still well in flower; some tubs about 1 ft. in diameter being a mass of bloom. S. *Bursariana* and S. *juniperina* are still in blossom, the latter having bright, golden, tassell-like flowers borne on short erect stems, 3 in. in height. On a fine plant of the mauve-coloured *Hepatica angulosa* I counted upwards of 100 flowers. Anemone ranunculoides opened its first blossoms to-day (April 2); they are of a bright yellow colour. The Utah Agave has proved to be perfectly hardy, having withstood the winter on the rockwork here. We have *Primula rosea*, P. *cashmeriana*, and P. *capitata*, all finely in bloom; the two latter are of the P. *denticulata* section, and on the under sides of their leaves is a golden farina. P. *spectabilis*, rosy-lilac; P. *nivalis*, pure white; and P. *marginata*, mauve, are now also in flower.—E. J.

Hardiness of Fortune's Gardenia.—Mr. Scott, of Auchen-dennan, has recently discovered by accident the hardiness of *Gardenia Fortunei*. A plant of this fine shrub, about 3 ft. high, and growing in a 10-in. pot, was thrown on to the rubbish heap. Six weeks afterwards, when the ground was bound hard with frost, and the foliage of plants all around was drooping, the plant of *Gardenia* was discovered, and was found to be the freshest evergreen about the place, although the ball was frozen through.—"Florist."

At the Royal Horticultural Society's show last week, Mr. Wills was awarded two gold medals; one for a group of plants arranged for effect, and the other for new and rare plants.

ANSWERS TO CORRESPONDENTS.

Æschynanthus grandiflorus.—*Anon.*—This requires a stove temperature and plenty of water in order to obtain free growth, without which free blooming cannot be expected.

Fuchsia Dominicana.—*Inquirer.*—This Fuchsia may be flowered early in winter by striking cuttings of it in spring and growing them on, keeping the shoots stopped and the flowers picked off until within six or seven weeks of the time when it is wanted to be in flower.—S.

Fruiting the Monstera.—At Hillsfield we found no difficulty in fruiting this plant. It was placed in a large pot on a slate stage close to the glass in the centre of the Orchid house, and a noble-looking object it was, throwing its fine foliage over the pathway on each side, and forming quite a bower to walk under. The pot in which it grew was placed about 3 ft. from a large tank of water, which the roots reached, and in which they ramified abundantly; thus circumvented it fruiting freely.—J. C. M.

Rose Houses.—As I am about to erect a small Rose house would you kindly inform me what are the dimensions of the one at Gunnersbury, and the angle of its roof?—*Subscriber, Dublin.* [Length, 42 ft, width, 23 ft; angle of elevation, 30°; width of borders round the house, 2 ft. 6 in.; depth, 2 ft. 6 in.; centre bed, width, 11 ft. 6 in.; depth of border, 2 ft. 6 in.; width of pathways, 3 ft. 6 in.—J. R.]

Setting Peaches.—Having read several remarks lately on the setting of Peaches by artificial means, such as by the use of Pampas Grass, feathers, &c., it occurred to me while thinning some Peach trees the other day that I would take the liberty of seeding a few shoots as fair samples of our trees here, which have had none of the above means applied in order to set the fruit. I never find the slightest difficulty in setting Peaches, Plums, or Cherries, without having recourse to such measures.—D. M. [Peaches could not possibly be set more thickly than those above alluded to. On a piece of shoot 44 in. in length we counted a dozen fruit.]

Shrub Pruning.—1. How, and at what time, should the white and yellow Jasmines be pruned? Do they flower on the wood made the previous year and also on two-year-old wood? 2. Should *Pyrus japonica* be pruned like an Apple or a Pear tree? 3. Does the white *Spiraea* ripen its crowns in this country sufficiently for forcing?—*Sub.* [Prune the Jasmines immediately after flowering. We always clip them with hedge shears. Nearly all their flowers are produced on shoots of the previous year's growth, but occasionally some few flowers appeared on spurs. The *Pyrus japonica* flowers most freely if pruned on the spur system, but a certain amount of new wood should be laid in annually to supply the place of any old shoots, the spurs of which have become long and unsightly. The white *Spiraea* never fails to ripen its crowns sufficiently for forcing, but it is well to have two sets of plants and to force them alternately, i.e., those forced this year, as soon as done flowering, should be planted out on a south border and allowed to flower next year in the open air, when they will be quite fit to force the following year.—W. W.]

Flowerless Stephanotis.—Mr. Baines says in reply to "H. H." (p. 248) that he has never met with one of the so-called flowerless varieties of *Stephanotis*, and that he considers bad management is the only cause of its not flowering. In this I cannot agree with him, as he perfectly sure that there are plenty of plants that do not flower in collection, owing, I believe, to their being seedlings. I have met with numbers of plants, well grown, but which would rarely flower, and which, when replaced by plants obtained from cuttings taken from flowering plants, succeeded admirably. I was recently at a sale of plants where a very fine *Stephanotis* full of buds was sold for a high price. Over seventy seedling plants were then sold at more than the usual nursery price for ordinary plants, because they were seedlings from the plant in question, amateurs imagining that they had obtained hybrids. This, I believe, explains the complaint so frequently made about flowerless plants of *Stephanotis*.—J. H. Lox, Crofton.

Root-eating Hollies.—Can you inform me what has eaten the roots of my young Hollies? Two years ago I planted a line of them 60 yards long, to form a hedge, and all went well until a few days ago, when I found several of the plants eaten off at the roots. Would you do this? The thick part of the root has entirely disappeared, nothing remaining in the ground but the small fibres. I am not sufficiently acquainted with the habits of the mole to know whether it would eat the roots of trees or not.—J. H., *Newton House, Ealington, York.* [My belief is that the mischief is done by the field mouse, and this is confirmed by the opinions of others to whom I have shown the section of the root. During the past winter, this little animal has been unusually busy, and I attribute to him the destruction of many scores of Austrian Pine, which he has attacked in the manner shown by the specimen sent. Seeing these completely ringed in many places after the severe weather of January and February, I concluded that rabbits had obtained access to them by climbing upon the snow drifts. The injured plants were removed and others put in their place, and since that time nearly every fresh plant has been injured. Some of the older ones are ringed 5 ft. from the ground, in places inaccessible to rabbits. Several mice of an unusually dark colour have been seen amongst the trees, and before many days are past I hope to hear that one has been caught in the act. The mice commenced upon several Scotch Pines, but these were evidently not to their taste and they returned to the Austrians.—A. J. BURROWS.]

Limes for Avenue or Street Planting.—The following kinds of Lime trees are said to be good for town planting, for which it is known

the common kind is unsuitable, owing to its early defoliation. The sorts recommended are *Tilia alba*, *T. macrophylla*, and *T. dasystyla*, which retain their fine bold leaves until most other deciduous trees are bare of foliage. *Tilia alba* is an old and well known tree, but it is not so often seen and planted as its merits demand; its leaves are larger than those of the common kind, and beautifully white on the under surface. The other two are remarkable for their large, handsome foliage, fully double the size of that of the common Lime; they are somewhat alike when seen, at a little distance, but when closely examined they are sufficiently distinct to be kept separate. *T. dasystyla* is not well-known nor perhaps plentiful, but it has two good qualities belonging to it; its leaves are large and fine and they hang on the tree till late in the season.—"Florist."

Names of Plants.—J. S. L. G.—1, *Croton spirale*, 2, *Gymnogramma Massoni*, 3, *Lygodium japonicum*, 4 and 5, undeterminable; 6, *Davallia dissecta*, 7, *Didymochloa truncatula*, 8, *Niphoebolus nipetris*, 9, *Selaginella casaria arborea*, 10, *Adiantum pentadactylon*, 11, *Adiantum Capillus-Veneris* variety, 12, *Nephrolepis undulata*. J. H. C.—The Cornelian Cherry (*Cornus Mas*).

Insects.—W. W. *Stickland.*—The grubs sent are apparently those of the weevil (*Otiorhynchus sulcatus*, the grub of which is a well-known gardener's enemy, and should be carefully looked after and destroyed.—W. W. S.

QUESTIONS.

Sweet-scented Camellia.—I have been told that there grows at Cintra, near Lisbon, a double white Camellia with scented flowers. Can any reader of THE GARDEN inform me whether this is so or not? and, if so, is it in commerce?—A. H. R.

Coleus Scottii.—If any of your correspondents have tried this for bedding purposes, I should be glad of their experience respecting it.—A. H. R.

Glass Structures.—As I am about erecting a range of glass consisting of a plant house and early and late Vineries, I should be glad to be informed as to the respective merits of span-roof houses as compared with half-span lean-to houses both for plants and Vines; also as to the cost and difficulty of heating them respectively.—R. S.

A Green Base for Dinner-table Plants.—The common practice of placing the plants on the dinner table in vessels of gold and silver may be varied occasionally with advantage. Bases may be arranged in the following manner:—Choose a number of circular pieces of board, $\frac{1}{4}$ in. thick, and from 9 in. to 12 in. in diameter; the larger circles will form a base for a plant in a 5-in. pot and the smaller for a 3-in. one. Edge the boards with narrow strips of perforated zinc, rising up above the face of the boards about $\frac{1}{2}$ in.; this is quite enough to hold the soil up till the Moss and other plants used completely cover it. In placing the Moss on the boards an empty pot of a suitable size should be held in the centre and the soil pressed round it, raising it up to the rim in an easy graceful curve. *Selaginella denticulata* will soon cover the soil and form a dense mass of elegant green, and, when required for use, the empty pot can be taken out and the plant dropped into the hole left. Although I have only mentioned the *Selaginella*, other plants, such as *Sedum glaucum* and *Mentha Pulegium gibraltaria* will do for a green base, whilst for coloured bases small cuttings of *Alternanthera*, dibbled in quite thickly, and placed in a close, warm pit, will soon furnish them well. *Tradescantia vittata* for a large base has a pretty effect; it is more spreading and less formal in its growth than most plants, and grows very rapidly. There is a good deal of green mixed with the cream colour in its variegated foliage that makes it effective under artificial light. In clothing these bases I rather prefer taking large spreading pieces of whatever plant I require, except the *Alternanthera*, laying the sprays on the little mounds of soil, and pegging them close down with very small pegs, using sprays enough to cover the whole well; then I sprinkle some sand over the top, water with a fine-rosed pot, and place them in a warm, shady situation. They do very well set among larger plants in the stove, or in any situation where warmth, moisture, and shade are present.—E. H.

JOBITUARY.

We have to record, with much regret, the death of JAMES STEVENSON, who, for upwards of thirty years, was gardener at Cobham Park, Surrey. The gardens there, with their extensive ranges of glasshouses, their fine fruit walls furnished with galvanised wires on which to train the trees, were wholly planned and laid out under his direction, and most complete they are acknowledged to be in every department. But gardening, proficient as he was in it, did not alone occupy Mr. Stevenson's attention; he was also a good architect; the schools in the village of Cobham, built in commemoration of the late Mr. Harvey Combe, were erected under his superintendence and from his designs, and he acted as clerk of the works during the building of the new mansion at Cobham Park. Both in public and private life he was much respected; his friends, of whom few had so many, have lost a genial, kind-hearted man, and horticulture one of her ablest practitioners. He died on Sunday morning last, at the comparatively early age of sixty.

SATURDAY, APRIL 12, 1879.

Vol. XV.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES OF THE WEEK.

Wild Gardening in Hyde Park.—A high bank at the end of the Serpentine has lately been prettily dotted with *Crocuses* of various colours and *Snowdrops*, which look very gay in the Grass, though they have not yet spread into the glowing tufts that one admires in country gardens. About London, owing to the plants being frequently disturbed, one rarely sees a handsome glow of *Crocuses*. As on such banks under trees as that at the Serpentine there is no need to mow the Grass until the *Crocus* leaves are ripened, these plants might there be allowed to grow undisturbed. In time they would probably prove a great attraction. We have noticed them sometimes more at home under trees where the Grass is poor or nearly absent than in open, rich, Grassy places.

Anemone stellata.—I have the white form of this *Anemone* now finely in flower. At first it is rather stained with purple, but when fully out it is a pure white star, with pale purple under petals. This with the black eye and the pretty foliage makes it a striking flower, and a very good addition to spring hardy plants. It was found wild near Rome about two years ago by my friend, Dr. Lowe, and is, I believe, very scarce.—H. N. ELLACOMBE, *Bitton*.

Hydrangea paniculata grandiflora.—This magnificent shrub has come through the past winter without the slightest injury, alive, in fact, to the tips, thus establishing its claim to rank among the hardiest occupants of our gardens. By-the-by, now is a good time to prune it. It should be cut in quite close, in order to ensure strong young growths and large heads of flowers.—T. SMITH, *Neurys*.

The Four-coloured Lachenalia (*L. quadricolor*).—We saw this handsome plant flowering in fine condition the other day at Chiswick. Its lance-shaped leaves are mottled with chocolate, and also the flower stem, which rises from 9 in. to 10 in. high, and bears several drooping bell-shaped flowers with a striking combination of colours, being scarlet below, then yellow and green, and tipped with deep chocolate. As a greenhouse plant it ought to be better known than it is, having now been in this country for many years.—W.

Andromeda floribunda.—Among the numerous kinds of spring-flowering shrubs few are capable of producing a more showy effect than this dwarf *Andromeda*, on account of the abundance of the pure white Lily of the Valley-like blossoms which it produces. When planted in masses, or associated with the drooping *Forsythia* (*F. suspensa*) and others, it is remarkably effective, and tends to relieve the naked appearance of the latter.—W.

Cypripedium Schlimi.—This appears to be almost a perpetual flowering Orchid. I have a plant of it under my care in a 10-in. pot, which has been flowering for fourteen months, not more than four or five days intervening at any time between the fading of one flower and the opening of another. At the present time it is bearing two spikes, with a third flower on each, and another spike is just about to commence flowering, so that, under favourable circumstances, it will continue in blossom for six months longer. The plant in question is grown in an ordinary stove, where, during the late severe winter, the thermometer averaged 46° for over a fortnight.—E. D.

Saxifraga retusa.—On the new and excellently constructed rockery at Chiswick, this little *Saxifraga* quite enlivens its surroundings by its dense cushion of pink blossoms. In our opinion it is much prettier than the ordinary *S. oppositifolia*, to which it is nearly related, as its small blossoms are produced in umbel-like clusters, and its growth is more compact. The common *Hepatica*, in a great variety of colours, is also a very attractive feature here, being planted in large masses on the shady side, thus forming a means of giving the rock garden a cheerful appearance at this the dulllest season for Alpine flowers.—W.

Chusan Palms and the Frost.—Several plants of *Chamaecyparis* excelsa that have stood fully exposed all the winter as green and healthy as possible; even the young immature leaves are not the least injured. As we had frost enough to kill such plants as *Stocks*, *Wallflowers*, and many of the so-called hardy spring flowers, there need now be no hesitation in planting this handsome *Palm* out-of-doors in any well-sheltered position with a good prospect of success.—J. G.

Camellia reticulata.—In the Royal Horticultural Society's Gardens at Chiswick, this *Camellia* is just now highly attractive, being literally covered with huge rosy blossoms, which are semi-double. Like the ordinary *C. japonica*, it is quite hardy, but it flowers far more satisfactorily under glass than out-of-doors; hence it is afforded the protection of a deep two-light pit, which it completely fills.—W.

Hardiness of Liliun neilgherrense.—A pot of this was plunged through the winter along with others in a cold frame, covered quite over with about 4 in. of sand. This pot was quite close to the side of the frame, and frozen quite through and through; nevertheless the bulb is now perfectly sound, and is making new roots.—T. SMITH, *Neurys*.

Dog's-tooth Violets in Grass.—A few days ago I saw a number of irregular clumps of these, dotted here and there on a gently sloping bank of turf, and, in front of clumps of evergreens, they looked quite charming, and their dark spotted leaves showed up to much better effect on the fresh green Grass than they do in borders. They were all of the red variety, and required a few of the white form among them to make the picture perfect.—T. SMITH, *Neurys*.

Hardy Primroses.—For the early decoration of the flower garden the different varieties of *Primrose* are well worth careful attention, as they not only afford a great variety of colour, but a long and continuous season of bloom. Many of our coloured single varieties that began to flower freely last autumn, after being ice-bound for weeks together, burst out in full beauty some time ago, and are now covered with blossom. The double varieties (white, sulphur, mauve) are now opening their flowers in such profusion as to quite conceal the foliage, the double white being exceptionally chaste and beautiful. They succeed admirably in sheltered beds among *Conifers*, &c., cutting winds being more destructive to them than frost.—J. GROOM.

Aucuba Berries.—We have some beds of *Aucuba* quite loaded with berries that are getting beautifully coloured. *Aucuba* flowers may be readily fertilised by planting a male *Aucuba* in the bed, or anywhere within the radius of a few yards. This is both simpler and more effectual than artificial fertilisation, which, on a large scale, is almost impossible.—J. G. L.

Hepaticas in Masses.—These charming spring flowers are now in full beauty with us. They should not be divided too frequently, as one good large clump is more effective than a dozen small ones. In cottage gardens in this neighbourhood they are largely grown, and few plants are prettier at this season of the year.—J. G., *Maidstone*.

New Park at Birmingham.—On Saturday last, the Mayor of Birmingham opened the new park at Small Heath, which has been presented to that town by Miss Ryland, and towards the laying out of which she has contributed £4000. The park is about 41 acres in extent, and is the eighth park which has been opened in Birmingham.

Plants in Flower in a Somersetshire Garden.—There are now in flower in my garden in Somerset (April 2) the following plants, viz., *Soldanella Wheeleri*, *Scilla præcox*, *Iris persica*, *Alpine Auriculas*, *Orubus niger*, *Viola lutea*, *Lungwort*, *Cyclamen coum* (red), *Saxifraga oppositifolia*, *Primula Golden Plover*, a variety of *Polyanthuses*, and *Puschkinia scilloides*. The following plants also are well in bud, viz., *Dicentra spectabilis*, *D. eximia*, *Camellia imbricata*, *Crown Imperials*, *Primula cortusoides*, *P. denticulata*, *Iberis gibraltarica*, a white *Veronica* with mauve stamens (the name of which I do not know). *Agapanthus*, which have been out all the winter, although cut down by frost which registered as low as 12° Fahr., are now shooting freely. Also, I hope to have saved a *Lapageria rosea* which was planted against a low south wall; this, I am glad to say, appears to be shooting, although the frost cut it down to the ground.—A. B. T.

Royal Horticultural Society.—It is understood, says the "Builder," that the "1851 Commissioners" have determined to take possession of the gardens at South Kensington; in fact, that they have formally demanded it and have been refused. The Law Courts will probably be appealed to to settle the precise legal position of the two bodies.

Edinburgh Professorship of Botany.—We learn that this has this week been filled by the selection of Dr. Dickson, Professor of Botany in the University of Glasgow, and previously in the University of Dublin, where he succeeded Dr. Harvey.

Mr. Hovey's Camellias.—Specimen plants of these beautiful new American *Camellias*, several of which received first-class certificates the other day at South Kensington, are now in flower in Mr. Bull's nursery at Chelsea. They are to be sold, we understand, at Stevens' Rooms on the 17th inst.

NOTES FROM KEW.

Hardy Plants.—The plant of *Blagay's Daphne* (*D. Blagayana*), from which our coloured illustration (Plate 143) was taken last year, is again in flower, though scarcely, if at all, larger than at that time, thus showing its slow rate of growth. A more desirable dwarf shrub for the choicest parts of the rock garden is not in cultivation. The dense terminal clusters of pure white blossoms, immediately surrounded by deep green leaves, added to the delicious perfume emitted by them, similar to that of its congener, *D. indica*, at once arrest attention. This charming novelty is a native of rocky places in various parts of Carniola, and, though, as yet, very rare in collections, it is one of the plants requiring to be sought after. The *Puschkinias* are charming little bulbous plants, and have a brilliant effect when associated with other spring-flowering plants. The rare *P. scilloides* (see our illustration last year) is a dwarf slender kind of spreading habit, producing abundance of flowers, about $\frac{1}{2}$ in. across, of a delicate mauve tint. What is known as *P. libanotica* (syn. *P. scula* of Van Houtte) is a very handsome kind growing about 6 in. high, of erect habit, with a pair of rather broad-channelled leaves, from which arises a loose raceme of blossoms, each about the size of a sixpenny piece, white with a blue stripe down the centre of each division. The variety *compacta* is a much superior kind with larger flowers arranged more densely and the blue markings brighter. All are natives of the Caucasus. Amongst the *Daffodils* the *Bulbocodium* or *Hoop-Petticoat* section is becoming interesting. The narrow-leaved form (*Narcissus Bulbocodium* var. *tenuifolius*) differs from the type on account of its narrow twisted foliage, and rather smaller flowers. A little Alpine form called *nivalis* is even smaller than the last in all its parts. It is found at high elevations on the mountains of Spain. Another charming Spanish kind is *N. rupicola* (syn. *N. juncifolius* var. *apodanthus*), but it differs from the Rush-leaved *Daffodil* in having smaller sized bright golden flowers, crimped crown, and in being very glaucous.

Greenhouse Plants.—The *Convallaria-like* *Spearanthes* (*S. convallarioides*) is a pretty Liliaceous plant, which grows about 9 in. high; it has lance-shaped leaves, from which arises the flower stem, bearing pure white blossoms $\frac{1}{2}$ in. across, of firm texture and arranged in a racemose manner. It is a native of China, near Shanghai. Though it flowers more freely under glass it is perfectly hardy. Some of the *Lachenalias* are very showy, notably the old *L. tricolor*, and also its variety *luteola*, with its flowers almost all yellow. *L. tigrina* is another very desirable kind; it has a brown and green mottled stem and drooping bell-like blossoms, scarlet and pale green tipped with deep chocolate. These, like the rest of the *Lachenalias*, are natives of the Cape, and therefore they require the protection of a cool house or frame. In some of the species of *Pelargonium*, we see colours that have not yet been infused into the hybrid varieties, and none is more striking in this respect than *P. ardens* var. *superbum*, which is truly a striking kind; it has large, hairy, somewhat heart-shaped leaves, and bears dense clusters of rich deep crimson blossoms, with the tips of the petals of a deeper shade. In No. 4 house free use is made of the broad-leaved *Kalmia* (*K. latifolia*), and a very pretty effect it has when mixed with other plants. The *Nepenthes-like* *Arisema* (*A. nepenthoïdes*) is a handsome novelty from Sikkim belonging to the *Arum* family. It is about 2 ft. high, has an erect stem, beautifully mottled with black, purple, and light green, and bears a pair of leaves divided into narrow wavy divisions. The blossom is not showy, being greenish, but the form is angular, the upper part resembling a pitcher of *Nepenthes*.

Stove Plants.—Some highly ornamental climbing plants now adorn the roofs of the Palm-house and stove, and amongst them the twining *Petrea* (*P. volubilis*) is very attractive. It has long, slender branches and oval, deep green leaves, from the axils of which are produced long, drooping racemes of star-like blossoms, consisting of a pale mauve calyx with narrow spreading divisions, considerably larger than the corolla, which is of the size and form of the common Violet, and of a deep bluish-purple tint. It soon drops after expanding, leaving the calyx, which remains in beauty for some time. It is a native of Vera Cruz, and a very old introduction to our stoves, though now but so seldom seen. It was the subject of a coloured illustration in *THE GARDEN* (Vol. XII., p. 40). Few occupants of the stove are more beautiful or useful for general cultivation than *Clerodendron Thomsoni*, an old introduction from Tropical Africa. The pure white lower parts of the blossoms form a striking contrast to the rich, deep crimson of the corolla, seldom seen even amongst tropical flowers, and the profusion with which they are borne, and the length of time during which they continue in perfection, much enhance their beauty. Near to this is *C. speciosum*, a garden hybrid, not nearly so attractive. The showy *Bignonia* (*B. speciosa*), with large, mauve-coloured flowers, pencilled with deep purple, is a highly desirable kind, perfectly amenable to greenhouse culture. It is a native of Uruguay, from whence it was introduced about forty years

ago. *B. purpurea*, which is flowering freely near the preceding, apparently differs but slightly, if at all, from it. *Thunbergia laurifolia* is another showy climber, with large, pale mauve blossoms, produced in long, pendulous racemes. The many-flowered *Pavonia* (*P. multiflora*) is a very ornamental shrub, belonging to the Mallow family. It grows about 18 in. high, and has rigid, slightly-toothed leaves, from 6 in. to 8 in. long. The flowers are produced singly from the axils of the upper leaves; they consist of an outer row of narrow bracts, about 1 in. long, arranged in a cup-like manner, enclosing the deep chocolate-coloured flower, from which a fringy tuft of stamens protrudes. It inhabits the primeval forests of Tropical America, and appears to be the same as the kind known as *P. Wioti*. *Phædranassa chloracra* is an interesting *Amaryllid*, with a stout flower-stem, nearly 3 ft. high, terminated by an umbel composed of about six blossoms, which are 2 in. long and tubular; the base and the tips are of a glaucous green tint, and the rest of a deep flesh colour. The leaves, like the stem and flowers, are also very glaucous. It is a native of Tropical America. More curious flowers in point of structure than those of *Mantisia saltatoria*, a plant belonging to the Ginger family, seldom come under observation; indeed, it is difficult to describe their strange form. They bear some resemblance to the insect known as *Mantis*, hence the generic name. They are also called *Opera Girls*, from the fanciful notion that they resemble dancing figures. The colour of the blossoms, as well as those of the stem and bracts, is pale purple, and there is a bright orange-coloured portion corresponding to the lip of an Orchid flower. Another member of the same family that comes from the same country, viz., the East Indies, is *Monolophus elegans* (syn. *Kempferia*), a plant which bears beautiful large flowers, with a rich purple lip, elegantly pencilled with darker lines, and the other parts pure white. They are, moreover, deliciously fragrant, and appear some time before the leaves.

Orchids.—The large-leaved *Dendrobium* (*D. macrophyllum*) is one of the best late flowering kinds; the numerous large violet-purple blossoms borne on long drooping stems are very attractive. The variety *superbum*, on account of its bright coloured and larger flowers, is an improvement on the original, and deserves a place in every collection. Considerably in the way of the last, but with much smaller blossoms, is a novelty from Moulmein, bearing the almost unpronounceable name of *D. rhodopterygium*. Another Moulmein kind is *D. dixanthum*, with orange-coloured flowers, rather small, and with a nearly round unfringed lip. *D. crystallinum*, with respect to the size and colour of the flowers, much resembles the old *D. Devonianum*, but lacks the beautiful fringed lip of the latter kind. *D. barbatulum*, which is a native of the vicinity of Bombay, is a charming kind. Its blossoms, which are of ivory whiteness, the lip being hairy at the base and tinged with yellow, are arranged in dense one-sided racemes on long slender stalks. It is a very useful kind for cutting purposes, as it lasts so long a time in perfection. One or two novelties among the *Lady's-slippers* attract attention; such as *Cypripedium Boxalli*, which seems to be a compromise between the well-known kinds *C. villosum* and *insigne*. It has the foliage of the former, but the markings and colour of the blossoms more nearly resemble those of the latter. *C. Argus*, a native of the Philippines, has mottled foliage, and flowers having a purplish lip, spotted side petals, and the upper part striped with green. The whole plant strongly resembles the rare Javanese kind *C. superbiens* (syn. *C. Veitchii*). *Odontoglossum ciriosum*, one of the best of its section, is still in flower. It is a variable kind in the matter of colouring and size of flowers, for in a small batch one may detect some well-marked forms. No collection of Orchids can be considered complete without this charming kind.—W.

New Fastigate Silver Poplar.—This, according to Professor Sargent, in the "Gardener's Monthly," has been called *P. alba Boileana*, in compliment to Dr. Charles Boile, of Berlin. Several very finely grown specimens of this pyramidal Silver Poplar may be seen, it is said, in the public garden of Teflis, and as the garden was laid out and planted by a fugitive Persian prince, whose name it still bears, it is probable that this tree was originally brought from Persia. The Fastigate Poplar is perfectly hardy, grows rapidly in any slightly moist soil, and is particularly remarkable for its habit and great size, completely dwarfing the Italian Poplar with which it is associated. The bark, even in old specimens, is smoothed out as if it were polished; it is of a clear bluish-green colour, without spots or cracks. The ramification is strong and characteristic. The brilliant white of the lower side of the leaves, which remains unchanged in its purity throughout the summer, makes a strong contrast with the dark green of the upper side, producing a striking effect, and rendering this tree visible at a long distance off. The wood of the Fastigate Poplar is of finer quality and more highly esteemed than that of the other Poplars. It is an ornamental tree of the first order, and can be highly recommended.

THE FLOWER GARDEN.

DRAPERY FOR THE TRUNKS AND BRANCHES OF TREES.

SOME time ago I saw a Weeping Willow, on the margin of a lake, that had its trunk clothed with Virginian Creeper, and the effect in autumn, when the sun shone through the drooping branches of the Willow—whose leaves were just becoming tinged with gold—upon the crimson of the creeper-covered trunk was rich in the extreme. The Everlasting Pea, both the rose-coloured and the white varieties, are very suitable for planting near small-growing trees, such as Laburnums, Thorns, or standard fruit trees, when such are grown in or within view of the grounds. In small places, where the orchard trees are planted on or near the lawn, some interest may be added to the plantation by covering the stems with some strong-growing creeper that is not easily destroyed, and I have seen

these Peas used for the purpose with good effect. Of course, they cannot be planted in orchards to which stock have access, as in such cases nothing would be permitted to live. Even the trees, until the stems become old and gnarled, must have protection. The Hop is a very effective plant for draping a thin specimen Arbor-vitæ, or Yew tree, but the shoots should be thinned out in spring, and not more than three or four allowed to climb up to the tree. When the leader emerges from the top of the bush, and throws its long, graceful wreaths of Hops over the dark green foliage, the contrast is most effective. In like manner the taller, stronger varieties of *Tropæolum* could be used on shrubs towards autumn without doing any harm, as the first frost would kill them, and they could be removed. After the first year there would be no occasion to plant any seeds of these *Tropæolums* round the shrubs, as enough would fall and winter in the ground to furnish sufficient and to spare. Clematises are well suited to plant at the base of deciduous trees and even Yews, especially those with light-coloured flowers, which are set off to advantage by the dark background. The accompanying woodcut represents a *Clematis montana* on the branch of a Yew tree which I saw last May at Great Tew, and very effective it was. Jasmines and Honeysuckles are general favourites for such purposes. But all these plants do better if planted before the trees become too old or the soil exhausted. In the case of any old tree it may be desired to clothe, some of the exhausted soil should be removed, and some fresh rich material substituted. But the new soil must not be placed much higher up the bole than it was covered by the old soil, or some mischief may arise to the bark of the tree and its health be injured. The Wistaria, if planted before its support has become old, will combine with excellent effect with any single specimen of not too dense a habit. Of course, the Beech should be avoided.

E. H.

HARDY BOG PLANTS AND THEIR CULTURE.

WATER-LOVING plants may, in cultivation, be conveniently divided into two classes, viz., those needing to be totally submerged and those requiring only the soil in which they are planted to be more or less constantly saturated for their successful treatment. The former class has already received full attention in *THE GARDEN* (Vol. XIV., p. 149), and it is the object of the following remarks to describe the most select and beautiful members of hardy bog plants which should be more generally found in cultivation than they are. One of the chief drawbacks to their introduction into gardens probably is that they require a situation that exists naturally in only few gardens; but to construct artificially on a small, or even on a large, scale, a place well adapted for the purpose is a simple matter. Where deep water aquatic plants are grown, bog plants should, of necessity, be an indispensable adjunct, as they flower under ordinary care when placed in pots or pans

upon elevated ridges or shelves, or planted on an ordinary raft made of rough planks, or on the more elaborate principle of the Wilson raft, the appearance of which, or some other simple and inexpensive contrivance, would be welcomed by most lovers of hardy plants. Again, those who are the fortunate possessors of a charming rivulet in proximity to the garden could form, without entailing much trouble, a capital bog garden by simply diverting the whole or part of its course so as to flow amongst rubble, &c., upon which bog soil could be placed, and if the position be in a slanting direction so much the better. In gardens where the above sources are not available, the best substitute is to take out the soil to a depth of 18 in., and then place a layer of clay about 6 in. thick at the bottom and sides, and on it put the soil, which for general purposes—and in which the majority of bog plants will thrive—should consist of three parts fibry peat, one part coarse sand, and one part leaf-mould. The surface should be undulated, so that those requiring less moisture may be

placed on the mounds. It will be found that even during summer comparatively a small amount of water occasionally is required to render it constantly swampy. For growing a few bog plants, or for isolated specimens, ordinary large-sized earthenware pans will be found to answer the purpose capitally. In planting the bog garden care should be taken that the strong-growing kinds will not, when fully developed, overrun those of weaker growth; hence it is advisable, as in the case of rock gardens, to set apart select spots for the more choice and rare kinds.

One great source of annoyance in connection with bog gardens is, that they are very liable to the depredations of the feathered tribe, which, in search of worms, play much havoc both with plants and soil, especially in spring; and if the usual mode of scaring be not effective, the choicest and smallest plants should be protected by pieces of

Clematis montana on a branch of Yew.

galvanised wire netting. Though this charming class of plants has been introduced from almost every temperate region, yet it is the bogs and swamps of North America that have afforded the most plentiful supply, and amongst them are some of the most beautiful. Amongst the choicest of these may be mentioned:—

The Virginian Meadow Beauty (*Rhexia virginica*), a plant which inhabits the sandy swamps of Virginia, &c. It is remarkable as being the only hardy member of the family to which it belongs. It is of a neat habit, with numerous erect, quadrangular stems growing about 1 ft. in height, and bearing for a considerable time during summer terminal clusters of rather large, rosy-purple blossoms with a central tuft of bright yellow stamens. Though reputedly difficult to manage in cultivation generally, it succeeds admirably in some gardens, delighting in a deep, moist, peaty soil, when afforded partial shade. It may be propagated freely by means of seeds, though a somewhat slow process, or by careful division in autumn, and in the operation every portion of the roots should be planted, as every small piece develops buds.

Another equally beautiful plant is

The Worm Grass (*Spigelia marilandica*), though it is questionable whether it succeeds best in a bog bed, or otherwise. The finest specimen of it which I ever saw was growing in a fully-exposed and sunny position in rich, stiff, loamy soil. It appeared to be in the most robust health. As it is generally assigned to bog culture, it is justifiable to include it in our list, but, wherever its position may be in the garden, it may be recommended as one of the most desirable hardy plants which we have, and one which should be included even in the choicest collection.

The Naked Coreopsis (*C. nudata*) is one of the most remarkable of the vast family of Composites. It so strikingly resembles the common Rush when not in flower, that it would be difficult to distinguish them, as the leaves are developed in the same cylindrical manner. The flowers are very beautiful, being about $1\frac{1}{2}$ in. across, of a bright rosy-purple, changing to a lighter hue, and having a yellow centre. They are borne on slender, forked stalks, about $1\frac{1}{2}$ ft. high, which bend gracefully, thus much enhancing its beauty. The only flowering specimen of this rarity which I have as yet seen is in the Kew collection, where it is apparently thriving well in a loamy soil in a moderately moist position. It is a native of Florida, inhabiting moist but exposed places.

Fringed Polygala (*P. paucifolia*).—One of the handsomest of all the Milkworths is this delicate little North American species. It grows only 3 in. or 4 in. high, has a creeping and branching rhizome, and bears slender, erect branches, each with four or five ovate leaves, and terminated by a small cluster of flowers, which resemble those of *P. Chamæbuxus* in form, but they are $\frac{3}{4}$ in. in length, and are of a bright rosy-purple colour. It inhabits sphagnum swamps in various localities, generally in mountainous districts. In cultivation it appears somewhat difficult to manage, but it apparently thrives best in peaty soil, to which has been added a little leaf-mould and white sand. It should be placed amongst the most select occupants of the bog garden. At present it is very rare in English gardens.

Yellow Milkwort (*P. lutea*).—This is scarcely less pretty or interesting. It produces its small, bright orange-coloured blossoms in globose heads, about $\frac{3}{4}$ in. in diameter, on stems from 3 in. to 6 in. high. It is much easier to manage than the preceding, delighting in moist, sandy places, conditions under which it is found in New Jersey and other parts of North America.

Helonias bullata.—This is another useful subject for the bog garden. It is of an erect habit, growing from 1 ft. to 2 ft. high, with a rosette of light green, oblong, lance-shaped leaves. The flowers, which are small but densely arranged in a racemose manner on erect stems, are rosy-purple, and are produced in the beginning of summer. This very handsome plant inhabits various parts of North America, abounding especially in New Jersey and Virginia, where it is found in swampy places. In cultivation it thrives well in peaty soil, and, like the preceding, requires an equable, moist, and not too wet position.

Grass of Parnassus (*Parnassia palustris*).—In addition to our native examples of this, the bogs of North America afford two others equally interesting and beautiful, viz., *P. caroliniana* and *P. asarifolia*. The former has larger flowers than our indigenous species, and the peculiar crown-like appendages inside the flower are fewer in number. *P. asarifolia* is also larger, but has kidney-shaped root leaves, otherwise they both much resemble *P. palustris*, and thrive under the same treatment in a compost of fibry peat, loam, and sand, and in a not too wet position in the bog garden.

Sclerolepis verticillata is an interesting and beautiful bog plant, nearly allied to *Eupatorium*. It has a dwarf, creeping habit and narrow leaves, arranged in whorls of five or six. The flower-heads terminate the branches and are of a beautiful mauve colour, and they last a long while in perfection. It should be allowed to creep about in the wettest parts of the bog; it is quite indifferent as to quality of soil, and is easily propagated by division or by means of seeds.

Galax aphylla, a member of the Heath family, is a most desirable plant for our purpose. It is an evergreen perennial, with roundish leaves, and during the greater part of the summer is adorned with an abundant supply of long and erect racemes of numerous small pure white blossoms. When established, it has a tendency to grow in huge, compact tufts, and when in flower forms a very attractive object. It thrives well in a deep, peaty soil, but should be placed in a not too wet position.

The Twin Flower (*Linnaea borealis*), belonging to the Honey-suckle family, is a charming little plant, dedicated to the naturalist Linnaeus. It is a slender, creeping, and trailing evergreen, with roundish, slightly-toothed leaves, in the axils of which are produced thread-like flower-stalks, which are forked, each bearing a small, bell-shaped, gracefully-drooping flower of a pale pink colour and very fragrant. It thrives admirably when grown under the same conditions as the preceding, but should be afforded partial shade. Besides being indigenous to North America, it also inhabits various parts of Europe, and comprises one of our native wild flowers, though somewhat rare.

Orchids.—Some of the North American representatives of these are especially noteworthy, such as the Moccasin-flower or showy Lady's-slipper (*Cypripedium spectabile*), which is generally acknowledged to be the finest of the genus, and well it merits that distinction. It is too well known to need description, more especially as an excellent coloured illustration of it will be found in Vol. XI. of THE GARDEN. The stemless Lady's-slipper (*C. aculea*), which inhabits shady, moist woods, is another fine kind, well deserving of culture, also the Ram's-head Lady's-slipper (*C. arietinum*), with its small, singularly-shaped blossoms. The small white Lady's-slipper (*C. candidum*) is a rare and very pretty kind, with rather small white and brownish flowers. The larger yellow Lady's-slipper (*C. pubescens*) should rank next to *C. spectabile* as regards size and elegance of blossoms, which have wavy, twisted, purplish-brown outer divisions and a bright yellow lip. All the above-mentioned kinds thrive admirably when associated with bog plants, and all delight in a deep, peaty soil and partial shade; they may be propagated readily by division in autumn or spring. *Calopogon pulchellus* is another beautiful little bulbous-rooted plant, well deserving of culture. It produces erect stems about 1 ft. high, clothed with narrow leaves, and in summer it bears at its apex from two to six blossoms, 1 in. across, of a pink-purple colour, with the lip beautifully bearded with white, yellow, and purple club-shaped hairs; it is, moreover, very fragrant. The *Ophioglossum-like* *Pogonia* (*P. ophioglossoides*) is a handsome kind, from 8 in. to 9 in. high, bearing but one large stem-clasping leaf, and a solitary flower, or rarely more, which is 1 in. in diameter, of a pale purple colour, with a crested and elegantly-fringed lip. The bulbous *Arethusa* (*A. bulbosa*), which inhabits the bogs in Virginia, &c., and which is now of frequent occurrence in cultivation, is an interesting as well as elegant little plant, which is very easy to manage. As its name implies, it produces small, globose bulbs, from which spring the small flower-stems, each bearing, in early summer, a single large blossom, of a lovely rose-purple colour, and sweet scented. There are various other North American terrestrial Orchids in cultivation of less striking beauty than those above mentioned, comprising the curious and rare Northern *Calypso* (*C. borealis*), which bears a large and showy purple and yellow flower; also the white-fringed *Orchis* (*Platanthera blephariglossa*), 1 ft. high, with beautiful pure white blossoms, with a delicately-fringed lip. The large purple (*P. fimbriata*) and the small purple *Orchis* (*P. psychodes*) are not uncommon in cultivation, and are especially noteworthy.

All the preceding kinds of Orchids thrive well in deep, peaty soil, and in partial shade, with the exception of the *Calypso borealis*, which delights to creep in wet, living Moss only. The hardy representative of the gorgeously painted foliage of the tropical *Anætochil* is undoubtedly the downy *Goodyera* (*G. pubescens*), which, although of not such bright colours, the silvery markings on the rich green foliage render it strikingly beautiful. It seems to thrive best in a somewhat shady position, but shade is not indispensable.

Insectivorous Plants.—It is a rather singular coincidence that the majority of the so-called insectivorous plants are natives of

the North American bogs and swamps, and of these there are several of sufficient hardiness to be grown in the open air in this country. Of these, probably the best known and hardiest is the purple Side-saddle flower (*Sarracenia purpurea*). Besides the beautiful markings of the pitcher-like leaves, it bears equally singular blood-red flowers, which, in the case of established plants, are freely produced annually. A still more remarkable plant, in point of structure, is the Californian Pitcher plant (*Darlingtonia californica*) which may now be included in the list, inasmuch as it has proved hardy enough to withstand the full vigour of our climate. Young plants may be obtained from seeds which germinate readily. The best and quickest mode of propagation is, however, by offshoots, which old-established plants throw out plentifully, and which soon make strong specimens. Another, the strikingly-curious Venus Fly-trap (*Dionaea muscipula*) is perfectly amenable to outside culture, with perhaps the protection of a bell-glass during the winter. Like the two preceding, it acquires under such treatment a robustness that is unknown to plants under indoor culture. Of about the same degree of hardiness is the Trumpet plant (*Sarracenia flava*), which inhabits the bogs of Virginia, &c. It differs from its congener (*S. purpurea*) in having its pitchers quite erect and much longer, and the flowers are yellowish. One mode of treatment is applicable to all the four preceding; they should be grown in a compost consisting of one part fibry peat broken roughly, one part live Sphagnum Moss chopped rather fine, and a little sand and broken charcoal. A layer of Moss should be placed on the surface, so that it will grow round the plants, thus tending to keep them in a healthy condition. Their position in the bog garden should be in the wettest part, but the ground should be raised where the plants are placed so that the surface may be somewhat dryer than about the roots.

Sundews.—Two beautiful Sundews inhabit the North American bogs besides those found in this country, viz., the slender Sundew (*Drosera linearis*), with long and very narrow leaves profusely bedewed with the viscid substance peculiar to all the Sundews. It is found on the shores of Lake Superior. The thread-leaved Sundew (*D. filiformis*) is another very handsome kind with still longer and narrower leaves, and with beautiful rose-coloured blossoms, which are produced at the end of summer. It is found in various parts of the United States growing in wet sand, a circumstance which should be noted, as a frequent cause of failure in cultivating this plant is treating it in the same manner as the other kinds; it should be grown in a compost of coarse river sand, with an admixture of a little fibrous loam, and should always be kept in a very moist condition.

Hooker's Chrysobactron (*C. Hookeri*) is a highly ornamental New Zealand plant, where it inhabits the margins of water-courses, boggy places, &c., growing in great abundance, forming clumps sometimes more than 3 ft. across, and, when in full blossom, it is said to afford a splendid sight, as vast areas are covered with its beautiful bright yellow flowers. Its foliage forms compact tufts, the leaves being about 1½ ft. long, narrow channelled, and of a glaucous green colour, shaded with brown at the base. The flower-spikes are leafless, and rise nearly 2 ft. in height, and the flowers are borne in a loose racemose manner, expanding in May or June. It thrives best in peaty soil mixed with a good sprinkling of river sand, and the soil should be constantly moist, but not too wet. It may be propagated freely from seeds, or by division, an operation which should be done in spring.

Samolus litoralis is another very elegant New Zealand bog plant, belonging to the Primrose family, but remarkably unlike one; it more resembles the Cranberry than any other plant with which we are familiar. It has numerous slender branches, 1 ft. to 1½ ft. long, with small, leathery, oblong foliage. For a considerable time during summer the branches are covered with rosy blossoms, ½ in. across, which are borne in the axils of nearly every leaf, thus rendering it very attractive. To be successful with it under culture, it should be grown in a rich, loamy soil, and be kept constantly moist and fully exposed. Propagation may be easily effected by means of the numerous suckers, or offshoots, or by seeds.

Capé Crinum (*C. capense*).—One of the showiest and most stately denizens of the bog garden is this charming bulbous plant and its varieties. As to its hardiness in the south there can be no doubt, as I have grown it for some years wholly unprotected during winter. It is the largest-growing, hardy bulbous plant we have, having bulbs, when fully matured, 6 in. in diameter, each developing numerous glaucous green leaves from 1 ft. to 2 ft. long, and 4 in. broad at the base, tapering to a point. The flower-stems are stout, rising considerably above the foliage, being from 2 ft. to 5 ft. high, each bearing from six to sixteen large flowers in an umbellate manner, varying in colour from almost white to a deep rose. The variety called *C. riparium* is the darkest, and there seems to be every intermediate shade between that and *C. fortuitum*, which is the lightest. *C. striatum* has the dark colour arranged in longitudinal stripes. The position of the

Capé Crinum in the bog garden should be where the roots will be in abundant moisture, but the bulbs raised and comparatively dry. It delights in a deep, rich, loamy soil, the stiffer, the better; in fact, it is advisable to put clay at the bottom, in order that the roots may revel in it. Young plants may easily be obtained from seed, which should be sown as soon as it is ripe; it may also be increased by division of the bulbs. If there be but one bulb, and it shows no sign of making offshoots, it should be cut over at the top, when it will immediately send out numerous shoots, by which it may be propagated.

Native Bog Plants.—Our native flora affords a few very desirable objects for the bog garden; indeed, some are not surpassed in beauty by the choicer exotics. Amongst these may be noted the Marsh Gentian (*Gentiana Pneumonanthe*), which inhabits low, healthy, moist places, growing from 6 in. to 12 in. high, with erect stems and narrow, pointed leaves. The flowers are borne in terminal clusters, and are from 1 in. to 2 in. long, bell shaped, of a lovely deep blue within, and with five broad, greenish lines corresponding with the divisions outside. The white variety, though rare, forms a charming contrast when associated with the type. It thrives best in a deep, peaty soil, where it is constantly moist. It may be increased by seeds or careful division in spring. The bog Asphodel (*Narthecium ossifragum*), with its Iris-like leaves, forms dense tufts from 6 in. to 8 in. high, and produces numerous elongated, straight racemes of rather large yellow flowers, succeeded by red capsules, which remain on the plant during winter. It delights in a spongy, wet place, with live Moss on the surface, in which the fibry, creeping roots like to creep. An elegant little plant, too, is the bog Pimpernel, which is found in various parts in wet, Mossy bogs. It has thread-like, creeping stems and roundish leaves, from the axils of which are borne its pretty pink blossoms on long, slender stalks. It will take care of itself if placed under the conditions mentioned above, and will soon cover large spaces. Grass of Parnassus (*Parnassia palustris*) is another very interesting bog plant, differing from its North American congener in its more numerous gland-like appendages inside the corolla, which give it a more fringed appearance. Like the other two kinds previously mentioned, it succeeds well in ordinary bog soil in a moderately wet position. The common Marsh Marigold makes a very showy plant, enlivening the bog garden in early spring with a profusion of its bright golden blossoms, and, on this account, it is well worth growing. *Caltha radicans* is a kind much resembling it, but it has a creeping habit, smaller flowers, and triangular, not heart-shaped, leaves. The British Sundews well merit attention, as they are scarcely less beautiful than the rarer exotic kinds, especially the common round-leaved kind (*Drosera rotundifolia*), with its rosette of dew-bespangled leaves and small spikes of white flowers. The Great Sundew (*D. anglica*) and the spatulate-leaved kind (*D. intermedia*) are less common; the former has longer and much narrower leaves than the latter, but both are copiously covered with viscid matter. They all thrive in company with the North American kinds before alluded to, and should be grown where they would be fully exposed and not likely to be overrun by plants of ranker growth. The Scottish Asphodel (*Tofoelia palustris*), a plant with the habit of an Iris in miniature, and spikes of pale yellow flowers, may also find a place amongst others. The Summer Snowflake (*Leucojum æstivum*) also deserves a passing notice, as it thrives better when grown with bog plants than in an ordinary border, and very valuable it is for the purpose with its drooping clusters of Snowdrop-like flowers. A moderately moist place and loamy soil will be found to suit it capitally. Some of the indigenous Orchids prefer bog treatment, and these include some of the best. The handsome lax-flowered Orchis (*O. laxiflora*) which inhabits the bogs and wet meadows in the Channel Islands, attains high perfection in the bog garden in rich, loamy soil; also the Marsh Orchis (*O. latifolia*), a larger and even finer kind, with long spikes of numerous blossoms, varying in colour from a pale rose to deep purple, and beautifully dotted with purple. The Marsh Helleborine (*Epipactis palustris*) is another handsome kind requiring like treatment, and one which would thrive better with an admixture of broken chalk to the compost. The Butterworts again are very pretty as well as curious little plants, always found growing wild in spongy bogs, amongst Moss, &c., and under these conditions they should be cultivated. The best is the Irish Butterwort (*Pinguicula grandiflora*) which inhabits boggy places in the south-west parts of Ireland. It has large Violet-like blossoms of a purplish-blue colour, white in the centre, and is the finest-flowering kind in cultivation. The common and Alpine sorts (*P. vulgaris* and *alpina*) are much smaller and less desirable. The Vallisneria-leaved Butterwort (*P. vallisneriaefolia*) which was the subject of a coloured illustration in the last volume of THE GARDEN, is sure to be a popular favourite when it shall have become better known than it now is.

The foregoing remarks allude chiefly to the choicer kinds of bog plants, but there are many others that might with advantage be associated with them, and especially those with hand-

some foliage which would considerably enhance the interest and beauty of the bog garden and break up the monotonous effect of dwarf vegetation. For instance, what fine specimens of the noble *Gunnera scabra* can be obtained in a short time under such treatment! also the fine-leaved Japanese Groundsel (*Senecio japonica*) and a host of others; but care should be taken when planting them that they are arranged so that the weaker and dwarfer kinds will not be overrun by them, though in many instances they afford the partial shade that is indispensable to the well being of some plants.

Subjoined is a list of desirable kinds adapted for bog culture, and the majority of them are readily procurable at most nurseries. Those marked thus * are British species.

Dwarf kinds which succeed best in peaty soil:—

<i>Coptis trifoliata</i>	* <i>Drosera anglica</i>
<i>Helonias bullata</i>	<i>Cornus canadensis</i>
* <i>Gentiana Pneumonanthe</i>	<i>Rhexia virginica</i>
<i>Galax aphylla</i>	<i>Chrysobactron Hookeri</i>
<i>Spigelia marilandica</i>	<i>Durandionia californica</i>
* <i>Anagallis tenella</i>	<i>Onoclea sensibilis</i>
* <i>Linnaea borealis</i>	<i>Lastrea novaboracensis</i>
<i>Sarcocolla purpurea</i>	thylyperus
* <i>Saxifraga Hirculus</i>	<i>Cypripedium spectabile</i>
<i>aquatica</i>	aristinum
<i>Sclerolepis verticillata</i>	guttatum
<i>Polygala paucifolia</i>	acule
<i>lutea</i>	caudatum
<i>Drosera linearis</i>	<i>Goodyera pubescens</i>
* <i>intermedia</i>	* <i>Narthecium ossifragum</i>
* <i>rotundifolia</i>	<i>Struthiopteris germanica</i>

Kinds that like rich, loamy soil, and being kept constantly

very moist:—

<i>Criauum capense</i> and vars.	<i>Hydrocotyle nitidula</i>
* <i>Callitha palustris</i> and fl.-pl.	<i>microphylla</i>
<i>leptosepala</i>	<i>moschata</i>
* <i>radicans</i>	<i>Lobelia siphylifolia</i>
* <i>Epipactis palustris</i>	<i>Primula sikkimensis</i>
* <i>Orcelis laxiflora</i>	Munroii
<i>foliosa</i>	* <i>Sagittaria sagittifolia</i> , var. fl.-pl.
* <i>latifolia</i>	<i>Panacratium rotatum</i>
* <i>palustris</i>	* <i>Pinguicula grandiflora</i>
<i>Myosotis palustris</i>	* <i>vallisnerifolia</i>
<i>Polygonum Brunonis</i>	* <i>vulgaris</i>
<i>Lachyris palustris</i>	<i>Swordia perennis</i>
<i>Tuibaghia alliacea</i>	* <i>Viola palustris</i>
<i>Symplocarpus foetidus</i>	* <i>Parnassia palustris</i>
* <i>Chrysosplenium oppositifolium</i>	<i>asarifolia</i>
* <i>alternifolium</i>	<i>coriandrina</i>
<i>Drosera bifloris</i>	* <i>Alisma Plantago</i>
<i>Gratiola officinalis quadridentata</i>	<i>Villarsia ovata</i>
* <i>Campanula hederacea</i>	* <i>reniformis</i>
<i>Corynephorus nudata</i>	* <i>alpina</i>
* <i>Leucojum aestivum</i>	* <i>lucatanica</i>
<i>Hydrocotyle bonariensis</i>	

The following are tall-growing kinds, all of which thrive in rich loamy soil, except those marked thus †, which require peaty soil:—

* <i>Butomus umbellatus</i>	<i>Tradescantia virginica</i>
<i>Hibiscus palustris</i>	<i>Scirpus lacustris</i>
<i>moschato</i>	<i>Equisetum Telmateia</i> , and others
<i>militaris</i>	* <i>Carex pendula</i>
<i>Gunnera scabra</i>	* <i>riparia</i>
* <i>Lythrum Salicaria</i>	<i>Arundo Phragmites</i>
<i>alatum</i> , &c.	<i>Donax variegated</i>
<i>Irises</i> , various	<i>Saxifraga peltata</i>
<i>Senecio japonica</i> (syn. <i>Erythrochaete</i>	<i>Justicia pedunculosa</i>
<i>pinnatifida</i>)	<i>Saururus cernuus</i>
<i>Eupatoriums</i> , any	Louiei
* <i>Cyperus longus</i>	* <i>Epilobium angustifolium</i>
<i>vegetus</i>	<i>album</i> var.
* <i>Osmunda regalis</i>	<i>Typia</i> , various
* <i>Rumex Hydrolapathum</i>	<i>Pyrethrum serotinum</i>
<i>Eriophorum polystachyum</i> , and other	* <i>Leucanthemum lucustris</i>
kinds	* <i>Spiraea Ulmaria</i>
<i>Phoridium tenax</i>	* <i>Aster tripollum</i>
* <i>Epilobium hirsutum</i> , &c.	<i>Lilium canadense</i>
* <i>Lysimachia thysiflora</i>	† <i>pardalinum</i>
* <i>vulgaris</i> , &c.	† <i>Robinsoni</i>

W.

Mistakes.—The "Rural World" in its report of the Missouri Horticultural Society, gives an amusing statement of the mistakes made by the different members as reported by themselves. Mr. Garrett said his mistake was in planting too many kinds of fruits. Esperant said he planted Hale's Early on too rich ground, causing rot. Mustard says his was in setting out too many Pears. Evans in not planting all Ben Davis Apples. Goodman in trying to raise fruit with the nursery business. Slocomb in going into the fruit business at all. Todd in planting too many sorts of Apples.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Selaginella Kraussiana.—"J. L." (p. 250) speaks of *Selaginella Kraussiana* (usually called in gardens *denticulata*) as having proved hardy with him this winter in an unheated house. I presume this is near London, but he does not say. With me the same plant has stood uninjured for three winters past in the open air on a Fern rockery quite unprotected, the thermometer having on one occasion been so low as 8° Fahr.—P. NEILL FRASER, *Rockville, Murrayfield, Edinburgh.*

Golden Feather Pyrethrum.—Where a large supply of this is in request, the most expeditious mode of obtaining it is to make a slight hotbed in a frame or brick pit in spring, and sow its seeds broadcast on finely-sifted soil. Only just cover the seed and keep the lights close until it germinates, when air may be gradually given, and as soon as the young plants are hardened off, the lights may be dispensed with altogether.—J. GROOM.

Tigridia Culture in New Jersey.—In THE GARDEN (p. 142) are some interesting remarks on *Tigridias*. While, however, your correspondent is right on most points, I cannot quite agree with him in some of his cultural directions, and especially when he recommends planting in "a partially shaded position." *Tigridias* do particularly well in my grounds, and I grow many thousands of them every year. The soil in which they are grown is very light and sandy, is manured only moderately, and is dug to a depth of not less than 1 ft. Instead of being best planted in partial shade, *Tigridias*, on the contrary, luxuriate in the broiling heat of our sunny summer weather, which seems to be but seldom, even in the slightest degree, either too hot or too dry for them.—GEORGE SUCH, *South Amboy, New Jersey, U.S.*

Nymphæa scutifolia.—Here, at the Cape of Good Hope, this and *Aponogeton distachyon* grow together; and as the *Aponogeton* has proved to be quite hardy in England, I am inclined to think that *Nymphæa scutifolia* will be found to be equally hardy. Should this on trial prove to be so, the following four plants would form a very pretty group, grown in ornamental water, viz., *Calla æthiopica*, *Nymphæa scutifolia*, *N. alba*, and *Aponogeton distachyon*.—CHARLES AYRES, *Cape Town, South Africa.*

Spring and Summer-blooming Clematises.—Although the spring-flowering varieties of the *Clematis* are yet best known as pot plants, and in this form are very effective for cool conservatory decoration, they are also most beautiful trained on a wire trellis or against a wall, or, indeed, in any place where climbers are at home and will thrive. A wall or fence devoted exclusively to varieties of the *Clematis* would be only half planted if the spring-blooming kinds were not included, as some two months of additional flower are lost if these be not planted. I have one showing flower buds already. All of this section bloom from the wood of the previous year, and therefore the pruning must be of the most careful description. Only late, weak shoots should be taken out, whilst the strongest should be left and regulated, the points being shortened back very moderately. The summer-blooming kinds flower on the wood of the present season, and the stronger the growth the greater the amount of bloom. The strongest growths invariably spring up from the base of the plant; therefore, the wood of the previous summer should be cut back in the following winter to within 1 ft. or so of the ground. As the spring growths have the first start, these should in all cases be kept close to the trellis or wall, and the young growths of the summer kinds should be carried over them, as they will have to be entirely removed in the winter, whilst the larger portion of the others will remain. These kinds should be planted alternately. I have found that the spring-flowering sorts, through the early ripening of their wood, have proved even harder during the past severe winter than has the summer bloomers, the wood of which is grosser, and therefore less able to withstand hard frost.—A. D.

Myosotis dissitiflora Best from Seed.—This favourite *Forget-me-not* has suffered much from the severity of the past winter, and will be very late in flowering. I find that seedling plants of it are much more vigorous and altogether better than those raised from cuttings, but, as it is not a free seedling variety, the difficulty lies in getting sufficient seed. The best plan is to plant a quantity of old plants, rather thinly, on a partially-shaded border, when the beds are cleared in May, covering them at once with a small-meshed fish-net to keep linnets and other small birds from the seed; allow the latter to scatter itself on the soil and keep it moist in times of drought. Abundance of seedlings will spring up that will be fit for transplanting in August, and they will make beautiful plants with which to furnish beds for spring display.—J. GROOM, *Linton.*

Sowing Stock Seed.—The frost this year has made a complete clearance of all kinds of Stocks, and as few flowers are more beautiful, either in a cut state or for the decoration of beds or bor-

ders, no time should be lost in getting seeds sown under some kind of glass covering. In a few flower-pots, pans, or boxes, enough plants may be raised for even a large garden, and by the end of April they may be planted out with a fair chance of being unchecked by cold weather. The Ten-week varieties are very beautiful for beds or borders, and so are the Intermediate kinds, especially the scarlets, purples, and whites. During mild winters established plants flower almost continuously through the year, but this season we must start afresh, and the best way in which to insure continuous blooming is to provide a deeply-trenched, well-fertilised root-run, for Stocks are strong-rooting subjects, and they grow and flower just in proportion to the way in which they are treated.—J. GROOM.

The Edelweiss. This interesting little Alpine has this winter proved to be perfectly hardy, having stood as an edging to a small round bed on the lawn without any protection whatever. It flowered here last year, and as clumps of it are now showing nine or ten crowns each, I hope to see it flower well during the coming season. Here, on the sandstone, it grows vigorously. I may add, that among Alpines in flower we have several varieties of *Hellebores*, *Hepaticas*, and *Aubrietia*, also *Saxifraga virginienensis* and a variety called *atro-purpurea*, one of the Moss section, which, either in or out of flower, is an acquisition on account of its beautiful green foliage and compact habit. Several tufts of *Anemone Pulsatilla* are also now coming into flower, and among *Primulas* we have *P. viscosa*, *P. capitata*, and *P. marginata*. *Cortusa Mathiola* has also got through the winter well.—A. B., *Pusey Gardens, near Faringdon, Berks.*

NEW AND RARE PLANTS.

A FEW NEW OR LITTLE-KNOWN PLANTS.

Aralia californica.—Those who are familiar with *A. racemosa*, a species indigenous to the Eastern States of North America, will readily recognise this, which may be succinctly described as a gigantic form of the plant named, reaching in its adult size a height of from 6 ft. to 8 ft. It is a smooth branching, herbaceous plant, with bipinnate foliage. The flowers, which are small and whitish, are produced in umbels, which are arranged in compound panicles, 1 ft. or 2 ft. long, and are succeeded by five-seeded, deep purple, berry-like fruits. It remains long in bloom, and will be found a useful and effective plant for the wild garden shrubbery, or for any situation requiring a vigorous habit of growth.

Coronilla libanotica.—Several pretty species of this genus are commonly cultivated, and this plant is not unworthy of being associated with them. It is a dwarf herbaceous species, forming a low bushy tuft of slender stems, clothed with neat pinnate-foliage, yielding an abundance of flowers in axillary umbels, of a creamy-white colour, fading to pale purple. It blooms the first season from seed, but more strongly the second year, and appears to be perfectly hardy, having stood without protection the recent severe weather.

Delphinium decorum.—Of tall perennial Larkspurs there is happily no lack, but the dwarf species are comparatively restricted in number. This plant can scarcely fail, therefore, to meet with a favourable reception, combining, as it does, a height not much exceeding 1 ft. with rather large, deep blue flowers on long foot-stalks, in an open raceme. The lower leaves are five-lobed, the upper ones with narrow linear divisions. I have no personal experience of this plant, but believe it will be found a perfectly hardy perennial of easy cultivation. The seeds much resemble those of *D. nudicaule* in size and form, and are hardly distinguishable from them. It is a native of California.

Erythrina herbacea.—Coral plants have long been represented in gardens by several fine species, and their beauty is such that they need but one addition to their good points, viz., greater hardiness, to render them the most popular of plants. The well-known *E. cristagalli* and the almost equally familiar *E. laurifolia* are occasionally met with in favoured localities, more or less completely exposed in summer; but even at Kew, they are generally planted in a pit from which the soil is removed in summer, and it is doubtful if they are ever seen in perfection when fully exposed. How far this plant will prove an efficient substitute for the older and better-known species remains to be seen, but, having been found to resist a New York winter, it may be fairly assumed to be sufficiently hardy for open-air cultivation in England, and it is eminently deserving of a trial. It is of rather dwarfer habit than the two species above-named, having a woody root-stock which throws up in summer, under favourable conditions, stems from 2 ft. to 4 ft. high, these stems being of two kinds, one sort bearing leaves only, the other only flowers with a very few leaves. The leaves are trifoliate, each leaflet being triangularly egg-shaped and stalked, and both stems and leaf-stalks are prickly. The flowering stems bear a raceme 1 ft. or 2 ft. long of narrow flowers,

each about 2 in. in length, the deep scarlet standard which in so many genera is erect, being here horizontal and folding over the wings and keel. The seeds are of bright scarlet, resembling those of *E. viarum*, and should be sown on heat as early as practicable, the seedlings being kept in a good frame the first winter. This species is a native of Texas, and is found as far north as Carolina, and westward to Sonora.

Fraseria speciosa.—This has a more robust habit, and bears somewhat larger flowers than *E. Parryi*. It is, like the plant just-named, a biennial of stout erect habit, growing from 3 ft. to 5 ft. high, with nerved leaves, in whorls of four to six, the lowest being 6 in. to 9 in. long, and about 2 in. wide, tapering into a long petiole, the upper ones connate and linear. The flowers are produced in umbel-like pedunculate cymes, the corolla being about 1 in. across, four-parted, rotate, of whitish colour, tinged with blue, and conspicuously dark dotted. At the base of each division are a pair of oblong and strongly-fringed glands with a fringe of eight to ten long bristle-like filaments. This is likely to prove an interesting plant, and will be best raised in a cold frame, the seedlings being subsequently planted out as early as is practicable, to obtain strong growth the first season. The seed may also be tried in the open ground, either with or without the aid of a hand-light. This plant is a native of Western America, from Colorado to California.

Gentiana affinis.—This is a neat sub-alpine species from the Rocky Mountains, with the general habit of growth of *G. pneumonanthe*, and, like it, perfectly hardy. It grows from 1 ft. to 1½ ft. high, with the foliage oblong to lanceolate, rough on the margins, and flowers six to twenty in number, arranged in a leafy spike or thyrsus. The corolla is deep blue, about 1 in. long, and nearly as much across, when expanded. Though less showy than *G. septemfida*, it is a desirable plant, and is quite as easy of cultivation. The seed is best raised in a cold frame, artificial heat being inadvisable with the plants of this genus.

Petalostemon Searlsiae.—The genus *Petalostemon* comprises an interesting group of Leguminosae, occurring chiefly east of the Rocky Mountains, having small pinnate foliage, and small flowers arranged in dense terminal bracteate cylindrical spikes. Two species are occasionally met with, *P. candidum* and *P. violaceum*, but they are scarcely to be found outside botanic gardens. *P. Searlsiae* is of recent discovery, having been first collected on the Pahranagat Mountains in South-eastern Nevada, by Miss Searls, whose name it appropriately bears. It is a perennial plant, with pinnate foliage composed of from five to seven oblong-linear leaflets, which with stem and branches are clothed with large glands, and a long, compact spike of rosy-purple flowers, which, though individually small, produce some effect by their number. It is probably quite hardy, and is deserving of a trial as a border plant, or even on the rockery.

Pentstemon Menziesii.—One distinct early-blooming form of this shrubby species of *Pentstemon*, with tubular pale violet flowers, has long been cultivated in gardens under the name of *P. Scouleri*, but the typical species is either unknown in cultivation or very rare. *P. Menziesii* resembles *P. Scouleri* in having obovate-oblong, toothed foliage, somewhat leathery in texture, under purplish beneath, with flowers of a reddish-purple in terminal one-sided racemes. The anthers are remarkable for being densely covered with long hairs. It is a native of California and the neighbouring States.

Silene pennsylvanica.—Although this pretty species of *Catchfly* is not entirely new to cultivation, seeds have hitherto been unobtainable, and it has consequently been scarce in gardens. It is of dwarf habit, seldom reaching 1 ft. in height, with numerous spreading stems furnished with foliage varying from spatulate to lance-shaped, and bearing rosy-purple flowers in terminal cymes, each blossom being about 1 in. across. When strongly grown, it forms an attractive border plant. It succeeds best in rather light sandy soil, but is not particularly fastidious in its requirements. It will occasionally produce flowers the first year, but more generally it does not blossom till the second season.

Quamoclit heterederafolia.—Under the somewhat loose name of scarlet Ivy-leaved *Ipomaea* *Quamoclit*, this pretty species has been offered by an eminent French firm. It is, however, totally distinct from the common *Cypress Vine* just named, differing both in its foliage and its inflorescence, the former being pedately five-lobed, and the latter, instead of being axillary and solitary, is produced in terminal clusters or cymes. The fine scarlet tint of the flowers and the profusion with which they are produced compensate for their rather small size. Its stems are very slender, and tinged with purple. It is said to be of very rapid growth, attaining a height of from 6 ft. to 8 ft. in a few weeks, and continues in bloom during the entire summer. It may be treated either as a half-hardy annual, in which case it should be sown under glass or on a hotbed in February or March; or as a hardy annual, the seeds being sown in April or May in the open ground. *Quamoclit heterederafolia* occurs over a wide extent of the South American Continent, and extends even to the West Indies.

Ipswich.

W. THOMPSON.

THE KITCHEN GARDEN.

TOMATOES AND THEIR CULTURE.

TOMATOES are fast rising in favour, and deservedly so, for unquestionably they are among the most useful and wholesome esculents grown. In America and on the Continent, where they are eaten fresh gathered from the plant, they are much more appreciated than they are here. The best-flavoured and most agreeable for eating without being cooked is Carter's Greengage, which, when perfectly ripe, is very handsome-looking, having a clear yellow skin that gives it a most tempting appearance. Last autumn, being fine and dry, Tomatoes were particularly good, and, although they may not be liked at first, one soon acquires a relish for them. It is not many years ago that people would not eat Rhubarb, bundles of which were offered in Covent Garden Market and could not be sold at any price, and yet, as is well known now, the consumption of Rhubarb is enormous. Owing to the more tender nature of the Tomato, and the consequent difficulty and expense of growing it in this country, fruit of it can never be very plentiful or cheap; but, from the free-bearing habit of the plants, and the heavy crop, they carry, I see no reason why it should not be offered at a much cheaper rate than it is. Early in the season, when produced under glass, the price must of necessity be high to be remunerative; but later on, when they ripen under the shelter of a wall or fence, or even in the open ground, they ought almost to be within the reach of all. So simple as regards culture, however, are they, that any one having the convenience of any ordinary garden frame to raise the plants in may grow a supply for themselves, as any building facing the sun will do to train them on, or they may be planted out in any warm border and supported by stakes, or be allowed to trail over the ground with their fruit resting on a few tiles or pieces of slate. These will keep them clean and by the warmth absorbed from the solar rays help to ripen the crop. To aid in doing this, it is necessary to trim out the superfluous branches, that the clusters of Tomatoes may have full and free exposure, light being essential not only to give them colour, but to impart flavour.

There are thousands of amateurs who, though not having much room, are in possession of small houses in which they winter their bedding plants, and when these are turned out, in nine cases out of ten these structures stand idle during the summer, but if filled with Tomatoes they might be very ornamentally furnished, and a heavy yield might be obtained. Nothing can possibly be more easy to manage, as the chief attention they require is plenty of water and the thinning already alluded to; if they get this and a tie occasionally to prevent their falling about, they are sure to do, for they are in no way subject to insects, or liable to get injured by inattention in the way most other plants are. What they like is plenty of air during the day to aid in setting the fruit, and once the crop is secured, an abundance of moisture at the root to assist in swelling it off. Soap-suds, or any mild sewage of that kind, proves most acceptable to the plants after they have filled their pots or boxes with roots, as does also soot or guano water, and if assistance be given in this way it matters little what soil is used, as they are sure to grow quite strong enough during the earlier stages of their existence, and up to the time when the fruits begin to swell. If it can be managed they do best trained to strained wires within 1 ft. or so of the glass after the manner of Vines or Cucumbers, in which way the huge clusters of fruit, hanging beneath the foliage, have a very ornamental appearance. Not only may Tomatoes be grown to perfection in this way or in pots in

any backyard, but they do well in boxes outside of windows, where trailing down or tied to a trellis they are objects of great beauty and utility.

To have them strong and fit for turning out-of-doors at the end of May, seed should be sown at once, and placed in any warm house or frame to induce it to germinate. Once up, it is necessary that the pot or pan containing it be stood near the glass where the plants can obtain plenty of light, otherwise they soon draw up weakly, as they do also if allowed to remain thickly together. It is best, therefore, as soon as they are large enough to handle, to pot them separately, or two in a 5-in. pot, from which they can be shifted on when they require more room. If they are intended to be turned out against a wall or on an open border, it should not be done till quite the end of May, and then only after the plants have been previously hardened, they being, when young, very tender and exceedingly susceptible of frost. For growing in houses or any spare pits or frames, the object should be to get them into a fruit-bearing state as quickly as possible, for, however early they commence they always keep on till destroyed by cold in the autumn, so that there is no fear of them ceasing to give a supply through exhaustion. The best kind to grow for culinary purposes is Hathaway's Excelsior, a fine large red sort almost as smooth and round as a ball.

S. D.

York Regent Potato.—Having known this variety ever since I can remember, I am confident that it is not a Dalmahoy, although, perhaps, there is not difference enough between them to give them separate names at Chiswick. In the west of England the York Regent is grown largely under several names, such as Early Orange, Early Knotts, Early Frame, &c., but it is always a second early, and generally sells well after the Ashleaves are over; but the haulm of the Dalmahoy, as grown by Mr. Scott, at Merriott, from Scotch seeds, is at least three weeks later in dying off, and the tubers in shape are very like the Victoria, but the skin is rougher, and the Potatoes, when seen in quantity, are rounder than those of that variety, though a few tubers may be mistaken for those of the Victoria.—HENRY FARR, *Bushey Grove*.

Dwarf Peas Unprofitable.—I fear that those who follow "A. D.'s" advice (p. 255), and sow such Peas as First Crop, Maclean's Wonderful, Laxton's Omega, Princess Royal, Premier, Veitch's Perfection, and others, with the intention of growing them well, or in any form to secure a crop without sticks, will find themselves greatly disappointed. Not one of the Peas just mentioned grows dwarfer than 2½ ft., and some of them, such as Princess Royal, attains the height of 5 ft. under ordinary cultivation. I have found, and I have no doubt others have done the same, that no Pea over 18 in. can be properly grown without sticks, and when they attain a height of 4 ft. or 5 ft. they require a great many sticks to support them. To grow Peas requiring no sticks, and be thoroughly on the safe side, Premium Gem, Little Gem, Maclean's Blue Peter, and Tom Thumb can be recommended. I have never found any of these to exceed 15 in. in height, and the crop which they produce is surprising for their size. But, at the same time, I may just say that I am not in favour of dwarf Peas at any time or in any garden, as they yield so very little in proportion to tall-growing kinds. After gathering one good dish from dwarf Peas, the best and most of the produce will have been secured; but tall-growing sorts generally yield a long succession of dishes, and to such an extent is this the case that I would recommend all to grow only the tall varieties of Peas. Where sticks cannot be secured for them, it will be found to pay handsomely in the end to buy wire hurdles for them. These will last any one's lifetime, and they answer the purpose for which they are intended capably. We grew dwarf Peas here at one time, so as to test them thoroughly, but we have now quite given them up as unprofitable.—CAMERLIAN.

New Plan of Preventing Lettuces Running to Seed.—The best heads of Lettuces often run to seed and become unfit for table. A German paper says this can be avoided by drawing a knife through one-half of the stem to which the head is attached. The sap, or, as it is called in Germany, the milk, will flow and rob the head of the power to open, yet enough sap will still remain to keep it fresh and growing for another week or so.

GARDEN DESTROYERS.

THE GOAT MOTH.

(COSSUS LIGNIPERDA.)

THIS insect, which is one of our largest moths, is very destructive, when in the caterpillar state, to various trees by boring long galleries in their stems and branches, which soon reduces them, particularly in the case of young trees, into an unhealthy condition, thus rendering them more liable to the attacks of various other insects; this is especially the case with Elms, which are very often attacked by Scolyti when in an unsound condition. The branches of trees bored by this insect are often so much weakened that they are very liable to be broken off by a high wind. The caterpillars have been found in the following trees, viz., Apple, Plum, Walnut, Oak, Ash, Willow, Poplar, Beech, and Lime; but they are much more common in the softer-wooded trees, such as the Willow and Poplar, than in the others. There are, unfortunately, but few means of destroying this insect. The moth may be found resting on the stems of trees during the day-time, but, though they are

so large, they are very difficult to find, as they much resemble the stems in colour. As the caterpillar usually passes the whole of its life within the wood of the tree, it generally escapes detection until its presence is betrayed by some portion of the tree flagging. If this part be carefully examined, a hole will always be found from which a mixed with small sawdust-like pieces of wood (the excrement of the caterpillars) is exuding; at times the neighbourhood of the insect may be detected by its strong and peculiar goatly smell. It is on account of this smell that this insect has been given the name of goat moth. Perhaps the best means of

stopping the ravages of the caterpillar is to cut off the bough, when practicable, in which it is, and then to destroy it; at times, by enlarging the entrance to the hole, the caterpillar may be killed by means of a long wire. Tobacco-smoke blown into the hole has been suggested as a means of dislodging the insect, but I am not aware if it has been tried with good effect. When in the chrysalis state they are quite as difficult to destroy, as they nearly always pass this period of their existence within the tree. The goat moth generally emerges from the chrysalis in June or July. The female soon afterwards lays her eggs, which are very numerous, from 700 to 1000; these are deposited beneath the outer bark of a tree by means of a strong ovipositor; by far the greatest number of these eggs are probably destroyed by some small parasitic insect, or there must be a great mortality amongst the young caterpillars, as few comparatively attain maturity. The newly-hatched caterpillars do not at once eat their way into the hard wood of the tree, but for the first year content themselves with the more sappy portion of the tree. They seldom or never leave their

galleries unless they cannot obtain the required amount of nourishment, or have been in some way disturbed. They do not attain their full size until they are nearly three years old, during which period they have changed their skins seven times. Besides the unpleasant smell which these insects always emit, they discharge a very strong-smelling liquid from their mouth, which is probably of some use in softening the wood. They are very strong, as the following experiment, made by a naturalist, will show:—One was placed under a bell-glass, weighing $\frac{1}{2}$ lb. (more than ten times the weight of the insect); this it raised with the greatest ease. A book weighing 4 lb. was then placed on the glass, and even with this weight in addition it raised the glass and escaped. The shape of the glass somewhat favoured the caterpillar wedging it up, as it were, with its head. Lyonnet has made a very interesting study of the anatomy of this caterpillar, and has found that its head contains 228 muscles, its body 1647, and its stomach and intestines 2186.

Some naturalists have tried to identify this caterpillar with the Cossus of the Roman *gourmets*, but one can hardly imagine

any one eating an insect with such a strong unpleasant smell, unless they were starving. When about to assume the chrysalis state the caterpillar forms a rough cocoon, composed of small pieces of wool and silk thread, round itself, near the entrance to its hole, within which it undergoes its change. Occasionally, however, the cocoons are formed in the earth at the foot of the tree. The moth measures from 3 in. to $3\frac{1}{2}$ in. across the wings when they are fully expanded; its body is stout and large, and about $1\frac{1}{2}$ in. long. The males are somewhat smaller than the females, and their antennæ more deeply toothed. The general colour of both sexes is brownish-grey, more or less dark;

The Goat Moth (*Cossus ligniperda*).

the body is striped with alternate transverse dark and pale bands. The upper wings are mottled with blackish-brown, and covered with innumerable small wavy, transverse lines of the same colour, with several dark bands of various lengths near the tips interspersed with various lighter patches; the lower wings are dark grey with darker markings, which are much less distinct than those on the upper wings. The full-grown caterpillars are about 4 in. in length, and nearly as thick as the finger. The head is black, and is furnished with a strong pair of jaws; the entire insect is very sparsely covered with short hairs. The chrysalis is yellowish with very well-defined joints, on the back of each of which are two transverse rows of short spines, of a darker colour, which point towards the tail; by means of these spines the chrysalis is able to work its way out of the cocoon and to the entrance of the hole, when the perfect insect is matured within it; the moth having escaped from the chrysalis case crawls on to the stem of the tree, leaving the empty case, as a general rule, at the entrance of the hole.

THE GARDEN IN THE HOUSE.

PLATE CLXXV.

AQUATICS IN BASINS.

THERE is an impression abroad that it is only those who have regular hot-house aquariums who can grow tender aquatics. This, however, is not the case, as there are numbers of handsome-leaved or flowering subjects that may be grown successfully even in basins. The beautiful *Nymphaea odorata* I first became acquainted with in a shallow milk basin that stood during the summer on one of the shelves of a stove, and well the plant grew and flowered. We give the names of a few of the species that may be cultivated in basins, with some particulars regarding their culture. The one we have named above is one of the best, as it is not of the strongest habit, and can easily be accommodated in a large milk basin; if considerably larger all the better. It may either be planted in a layer of soil laid in the bottom of the basin, or it may be potted in a 6-in. pan, which should be submerged a few inches below the rim of the basin. The flowers are white and deliciously scented. It will grow either on a sunny, warm shelf in a greenhouse during summer, or in a stove or in favourable localities outdoors. The basin should be kept full of water, and, to prevent a green scum forming on the surface, fresh and clean soft water should be added weekly by pouring it into the basin through a coarse-running rose until the scum has been run off over the sides. The object of giving the water through a rose instead of a spout is to prevent the soil from being stirred and making the water muddy. Another grand subject is the *Nymphaea candidissima*, the flowers of which are amongst the best of subjects for decoration in a cut state. The plant grows well enough out-of-doors, but it does not flower freely except in favourable localities, unless warm water be run into the tank daily to keep the temperature of the water above the normal figure. Where the waste water from a hot-water tank was allowed to run into an outdoor tank in which this *Nymphaea* was planted, we have known it to do well and flower most profusely during the summer, while in another tank in the same garden, but not so heated, the growth was equally strong and vigorous, but flowers were scarce. And this applies to most of the exotic aquatics grown in garden ponds and pools, which, as often as otherwise, might be heated at very little expense or trouble. When grown in a basin *N. candidissima* requires a pretty large one, 2 ft. inside at least, and if wider all the better. As it requires rather deep water, too, it cannot very well be potted, but should be planted out in the bottom of the basin. The same directions apply to the beautiful *Aponogeton distachyon*. It, too, likes deep water and room for the spread of its leaves. It is a rapid-growing plant, and is soon up and in flower. A plant of ours, grown in a basin under a frame with other aquatics, was in flower this spring in less than three weeks after the root had been planted. The beautiful pearly-white flowers are so deliciously and strongly scented, that the perfume of one flower pervades a whole structure. The foliage of the plant is also pretty and interesting, and in the still atmosphere of a glass house the leaves arrange themselves beautifully on the surface of the water, always keeping their upper surface perfectly dry and clean. Flowering aquatics that it is desirable to cultivate in the way here described are necessarily limited, and of the hardier species the above three are the best, but there are one or two hot-house *Nymphaeas* that may be added to the list. These are *Nymphaea Devoniana* and *N. cerulea*. The first has beautiful crimson and the last blue flowers; both are beautiful varieties. They however need a stove heat or a temperature between a stove and a greenhouse, otherwise they require the same treatment as the others. As to general treatment, all the species named should have a position near the glass and abundance of light; the more sunshine the plants receive the better they will grow and flower; shade ruins the plants. The sunny side of a greenhouse or stove is the best place for them, but for the first-named a cold frame is as good as anything. Of course, where these grow well enough outdoors there is no need to grow them under glass, but all are natives of much warmer countries than ours, and they enjoy a high temperature and produce cleaner and finer flowers under glass. We have seen the whole of them grown splendidly in a Victoria tank, where the temperature was much above their requirements; besides, when grown under glass the plants can be had in flower much earlier in the year, and later also. As regards winter treatment, it is not necessary to keep the plants in the house except when they are growing. For convenience the water may be poured off about November, and the plants may be taken up and laid in soil in any corner where the light is not entirely excluded; if they are kept moist they will keep well enough and begin to push in spring, when they may be again planted in the basins. Of course, the different species must be kept in a suitable temperature. The hardy sorts will do anywhere where they are safe from frost, and the stove plants may be placed in any corner of that structure.

CHIEF.

ROSES JEAN LIABAUD AND M. E. Y. TEAS.

Drawn by ALFRED PARSONS.

ON a pleasant morning in June I left my hotel in one of the squares of Lyons, and travelled by the short tunnel railway at an angle of 45° to the manufacturing district of La Croix-Rousse. Here, high above the rest of the city, I looked down on the fine streets and squares which lie in the angle of the two rivers, the Rhône and Saône, which meet just below the town. Up through the main street, the old-fashioned garden of M. Jean Liabaud is reached, the raiser of the dark Rose illustrated in the accompanying plate. Here I had a hearty welcome, and was shown M. Liabaud's best Roses, seedlings and others, amongst them Jean Liabaud. We owe to M. Liabaud two or three distinct families of Hybrid Perpetuals, the very dark race of which his Monsieur Boncenne and Baron de Bonstettin were the first, culminating in this splendid Rose, Jean Liabaud, now figured, which is really well represented in everything but in form, which is hardly good enough, the petals being usually more evenly arranged than in the flower from which the drawing was prepared. Elie Morel, Marquise de Mortemart, and Anna Alexieff are some of M. Liabaud's seedlings, but it is the race of which the best representation is here given, for which we are most indebted to M. Liabaud, containing, as it does, the fine climbing Roses named above. His Roses are good, and his description of them never too ornate. M. E. Y. Teas is, perhaps, the finest-shaped of any of the Hybrid Perpetuals, and no prettier sight can be seen in the Rose nursery than rows of this beautiful kind in full bloom. Nearly every flower is perfect, and the difficulty is, when cutting for exhibition, to choose the most beautiful. Would it were rather more vigorous, says the Rose grower; but, alas! how few things are perfect. It is very free flowering, and is richly scented. The raiser of it is M. Eugène Verdier, of Paris, to whom we are indebted for many good Roses.

Cheshunt, Herts.

GEORGE PAUL.

MR. WM. MORRIS ON THE ART OF THE FUTURE.*

I WISH people to understand that the art we are striving for is a good thing that all can share, that will elevate all; in good sooth if all people do not soon share it, there will soon be none to share; if all are not elevated by it mankind will lose the elevation it has gained. Nor is such an art as we long for a vain dream; such an art once was in times that were worse than these; when there was less courage, kindness, and truth in the world than there is now; such an art there will be hereafter when there will be more courage, kindness, and truth, than there is now in the world. Let us look backward in history once more for a short while, and then steadily forward till my words are done.

I began by saying that part of the common and necessary advice given to art students was to study antiquity; and no doubt many of you, like me, have done so; have wandered, for instance, through the galleries of the admirable museum of South Kensington, and, like me, have been filled with wonder and gratitude at the beauty which has been born from the brain of man. Now, consider, I pray you, what these wonderful works are, and how they were made; and, indeed, it is neither in extravagance nor without due meaning that I use the word wonderful in speaking of them. Well, these things are just the common household goods of those past days, and that is one reason why they are so few and so carefully treasured. They were common things in their own day, used without fear of breaking or spoiling—no rarities then—and yet we have called them wonderful. And how were they made? Did a great artist draw the designs for them—a man of cultivation, highly paid, daintily fed, carefully housed, wrapped up in cotton wool, in short, when he was not at work? By no means. Wonderful as those works are, they were made by "common fellows," as the phrase goes, in the common course of their

* From an Address to the Students of the Birmingham Society of Arts school of Design, delivered on February 19.

daily labour. Such were the men we honour in honouring those works. And their labour—do you think it was irksome to them? Those of you who are artists know very well that it was not; that it could not be. Many a grin of pleasure, I'll be bound—and you will not contradict me—went to the carrying through of those mazes of mysterious beauty, to the invention of those strange beasts and birds and flowers that we ourselves have chuckled over at South Kensington. While they were at work, at least, these men where not unhappy, and I suppose they worked most days, and the most part of the day, as we do. Or those treasures of architecture that we study so carefully nowadays—what are they? How were they made? There are great minsters among them, indeed, and palaces of kings and lords, but not many; and, noble and awe-inspiring as these may be, they differ only in size from the little grey church that still so often makes the commonplace English landscape beautiful, and the little grey house that still, in some parts of the country at least, makes an English village a thing apart to be seen and pondered on by all who love romance and beauty. These form the mass of our architectural treasures, the houses that everyday people lived in, the unregarded churches in which they worshipped. And, once more, who was it that designed and ornamented them? The great architect, carefully kept for the purpose, and guarded from troubles? By no means. Sometimes, perhaps, it was the monk, the ploughman's brother; often, his other brother, the village carpenter, smith, mason, whatnot—a common fellow, whose common every day labour fashioned works that are to-day the wonder and despair of many a hard-working "cultivated" architect; and did he loathe his work? No, it is impossible.

I have seen, as we most of us have, work done by such men in some out-of-the-way hamlet—where to-day even few strangers ever come, and whose people seldom go five miles from their own doors—in such places, I say, I have seen work so delicate, so careful, and so inventive, that nothing in its way could go further. And I will assert, without fear of contradiction, that no human ingenuity can produce work such as this without pleasure being a third party to the brain that conceived and the hand that fashioned it. Nor are such works rare. The throne of the great Plantagenet or the great Valois was no more daintily carved than the seat of the village mass-john or the chest of the yeoman's good wife. So you see, there was much going on to make life endurable in those times. Not every day, you may be sure, was a day of slaughter and tumult, though the histories read almost as if it were so, but every day the hammer clinked on the anvil, and the chisel played about the Oak beam, and never without some beauty and invention being born of it, and consequently some human happiness.

That last word brings me to the very kernel and heart of what I have come here to say to you, and I pray you to think of it most seriously—not as to my words, but as to a thought which is stirring the world, and will one day grow into something. That thing which I understand by real art is the expression by man of his pleasure in labour. I do not believe that he can be happy in his labour without expressing that happiness; and especially is this so when he is at work at anything in which he especially excels. A most kind gift is this of Nature, since all men, nay, it seems all things, too, must labour, so that not only does the dog take pleasure in hunting, and the horse in running, and the bird in flying, but so natural does the idea seem to us that we imagine to ourselves that the earth and the very elements rejoice in doing their appointed work; and the poets have told us of the spring meadows smiling, of the exultation of the fire, of the countless laughter of the sea. Nor until these latter days has man ever rejected this universal gift, but always, when he has not been too much perplexed, too much bound by disease or beaten by trouble, has striven to make his work at least happy. Pain he has too often found in his pleasure, and weariness in his rest, to trust to these. What matter if his happiness lie with what must be always with him—his work? And, once more, shall we who have gained so much forego this gain, the earliest, most natural gain of mankind? If we have to a great extent done so, as I verily fear we have, what strange fog-lights must have misled us; or rather let me say, how hard pressed we must have been in the battle with the evils we have overcome, to have forgotten the greatest of all evils. I cannot call it less than that. If a man has work to do that he despises, that does not satisfy his natural and rightful desire for pleasure; the greater part of his life must pass unhappily and without self-respect. Consider, I beg of you, what that means, and what ruin must come of it in the end. Oh, if I could only persuade you of this, that the chief duty of the civilised world to-day is to set about making labour happy for all, to do its utmost to minimise the amount of unhappy labour—nay, if I could only persuade some two or three of you here present—I should have made a good night's work of it.

Do not, at any rate, shelter yourselves from any misgiving you may have behind the fallacy that the art-lacking labour of to-day is happy

work—for the most of men, it is not so; it would not take long, perhaps, to show you that the would-be art which it produces is joyless. But there is another token of its being most unhappy work, which you cannot fail to understand at once—a grievous thing that token is—and I beg of you to believe that I feel the full shame of it as I stand here speaking of it; but if we do not admit that we are sick, how can we be healed? This hapless token is that the work done by the civilised world is mostly dishonest work. Look now; I admit that civilisation does make certain things look well, things which it knows, consciously or unconsciously, are necessary to its present unhealthy condition. These things, to speak shortly, are chiefly machines for carrying on the competition in buying and selling, called falsely commerce, and machines for the violent destruction of life—that is to say, materials for two kinds of war, of which kinds the last is no doubt the worst, not so much in itself, perhaps, but because on this point the conscience of the world is beginning to be somewhat pricked. But on the other hand, matters for the carrying on of a dignified daily life, that life of mutual trust, forbearance, and help, which is the only real life of thinking men—these things the civilised world makes ill, and even increasingly worse and worse. If I am wrong in saying this, you know well I am only saying what is widely thought, nay widely said, too, for that matter.

It is quite true, and very sad to say, that if anyone nowadays wants a piece of ordinary work done by gardener, carpenter, mason, dyer, weaver, smith, what you will, he will be a lucky rarity if he get it well done. He will, on the contrary, meet on every side with evasion of plain duties, and disregard of other men's rights; yet I cannot see how the British working man is to be made to bear the whole burden of this blame, or indeed the chief part of it. I doubt if it is possible for a whole mass of men to do work to which they are driven, and in which there is no hope and no pleasure, without trying to shirk it—at any rate, shirked it has always been under such circumstances. On the other hand, I know that there are some men so right-minded that they will, in despite of irksomeness and hopelessness, drive right through their work. Such men are the salt of the earth. But must there not be something wrong with a state of society, which drives these into that bitter heroism, and the most part into shirking, into the depths often of half-conscious self-contempt and degradation. Be sure there is. That the blindness and hurry of civilisation as it now is have to answer a heavy charge as to that enormous amount of pleasureless work—work that tries every muscle of the body and every atom of the brain, and which is done without pleasure and without aim—work that everybody who has to do with it tries to shuffle off in the speediest way that dread of starvation or ruin will allow him. I am as sure of one thing as that I am living and breathing, and it is this: that the dishonesty in the daily acts of life, complaints of which are in all men's mouths and which I can answer for it does exist, is the natural and inevitable result of the world, in the hurry of the war of the counting-house and the war of the battle-field having forgotten—of all men, I say, each for the other, having forgotten that pleasure in our daily labour which Nature cries out for as its due. Therefore, I say again, it is necessary to the further progress of civilisation that men should turn their thoughts to some means of limiting, and in the end of doing away with degrading labour.

I do not think my words hitherto spoken have given you any occasion to think that I mean by this either hard or rough labour. I do not pity men much for their hardships, especially if they be accidental, not necessarily attached to one class or one condition, I mean. Nor do I think (I were crazy or dreaming else) that the work of the world can be carried on without rough labour, but I have seen enough of that to know that it need not be by any means degrading. To plough the earth, to cast the net, to fold the flock—these, which are rough occupations enough, and which carry with them many hardships, are good enough for the best of us, certain conditions of leisure, freedom, and due wages being granted. As to the bricklayer, the mason, and the like—these would be artists, and doing not only necessary but beautiful and therefore happy work, if art were anything like what it should be. No, it is not such labour as this which we need to do away with, but the toil which makes the thousand and one things that nobody wants, which are used merely as the counters for the competitive buying and selling falsely called commerce, which I have spoken of before—I know in my heart, and not merely by my reason, that this toil cries out to be done away with. But besides that, the labour which now makes things, good and necessary in themselves, merely as counters for the commercial war aforesaid needs regulating and reforming. Nor can this reform be brought about save by art; and if we were only come to our right minds, and could see the necessity for making labour sweet to all men, as it is now to very few—the necessity, I repeat, lest discontent, unrest, and despair at last swallow up all society. If we, then, with our eyes cleared, could but make some sacrifice of things which do us now no good, since we unjustly and uneasily possess them, then indeed I believe

we should sow the seed of a happiness which the world has not yet known, of a rest and content which would make it what I cannot help thinking it was meant to be, and with that seed would be sown also the seed of real art, the expression of man's happiness in his labour—an art made by the people, and for the people, as a happiness of the maker and the user. That is the only real art there is, the only art which will be an instrument to the progress of the world, and not a hindrance.

I believe there are two virtues much needed in modern life, if it is ever to become sweet; and I am quite sure they are absolutely necessary in the sowing the seed of an art which is to be made by the people and for the people, as an happiness for the maker and the user. These virtues are honesty and simplicity of life. To make my meaning clearer I will name the opposing vice of the second of these—luxury—to art. Also I mean by honesty, the careful and eager giving his due to every man, the determination not to gain by any man's loss, which in my experience is not a common virtue. But note how the practice of either of these virtues will make the other easier to us. For if our wants are few, we shall have but little chance of being driven by our wants into injustice; and if we are fixed in the principle of giving every man his due, how can our self-respect bear that we should give too much to ourselves? And in art, and in that preparation for it without which no art that is stable or worthy can be, the raising, namely, of those classes which have heretofore been degraded, the practice of these virtues would make a new world of it. For if you be rich your simplicity of life will both go towards smoothing over the dreadful contrast between waste and want, which is the great horror of civilised countries, and will also give an example and standard of dignified life to those classes which you desire to raise who, as it is, indeed, being like enough to rich people, are given both to envy and to imitate the idleness and waste that the possession of much money produces. Nay, and apart from the morality of the matter, which I am forced to speak to you of, let me tell you that though simplicity in art may be costly as well as uncostly, at least it is not wasteful, and nothing is more destructive to art than the want of it. I have never been into any rich man's house which would not have looked the better for having a bonfire made out-side of it of nine-tenths of all that it held. Indeed, our sacrifice on the side of luxury will, it seems to me, be little or nothing, for as far as I can make out what people usually mean by it, it is a gathering of possessions which are but sheer vexations to the owner, or a chain of pompous circumstances which checks and annoys the rich man at every step. Yes, luxury cannot exist without slavery of some kind or other, and its abolition will be blessed like the abolition of other slaveries, by the freeing both of the slaves and their masters. Lastly, if, besides attaining to simplicity of life, we attain also to the love of justice, then will all things be ready for the new spring time of the arts. For those of us who are employers of labour, how can we bear to give any man less money than he can decently live on, less leisure than his education and self-respect demand; or those of us who are workmen, how can we bear to fail in the contract we have undertaken, or to make it necessary for a foreman to go up and down spying out our mean tricks and evasions; or we the shopkeepers, can we endure to lie that we may shuffle off our losses on to someone else's shoulders; or we the public, how can we bear to pay a price for a piece of goods which will help to trouble one man, to ruin another, and starve a third; or, still more, I think, how can we bear to use, how can we enjoy something which has been a pain and a grief for the maker to make?

TREES, SHRUBS, AND WOODLANDS.

THE ROYAL FORESTS.

DURING the last few years much has been written respecting these Crown lands which is in the highest degree misleading. Such paragraphs as the one from "Truth," which was lately printed in your columns would make it appear that the small income derived from these valuable possessions of the State is the result of mismanagement on the part of the Commissioners entrusted with the care of them. This illusion is quickly dispelled by a careful examination of the "Report of Her Majesty's Wood, Forest, and Land Revenues," which was printed by order of the House of Commons in July, 1878. Leaving out of consideration the Royal park and woods at Windsor, which, as the surroundings of a Royal residence, the abode of Her Majesty, are as much a national duty to maintain in the highest state of order as any of the public parks in the metropolis, the other forests might soon become by wise legislation sources of vastly increased national profit. But the half-hearted measures adopted for some years past have so hampered the action of the Commissioners, that in spite of the most earnest protests on their part, they are compelled to look on while year after year the property of the State

is sacrificed to private interests. That this is not allowed to pass without protest is shown by the able report of Commissioner Howard, who, in speaking of the laws at present regulating the management of the New Forest, characterises their effect as "producing a gratuitous transfer of the property of the State to private landowners—a measure neither supported by precedent nor founded upon principle," and in this sentence lies the gist of the whole matter.

The total area of the New Forest is 91,000 acres, 2,000 of which are the property of the Crown absolutely, and 26,000 acres belong to private landowners, but are subject to the Crown's forestal rights. This leaves about 63,000 acres to be dealt with by the Commissioners. From this the income of the past year amounted to about £12,000, while the expenditure was about £10,000. Before the introduction of the Bill of 1851, the Crown was entitled to the soil and freehold of the 63,000 acres and to forestal rights, as well as to powers of enclosure for planting and powers of management. When the trees within the enclosures were "past danger of browsing of deer, cattle, or other prejudice," they were to be laid open and an equivalent quantity of land enclosed. At the same date the rights possessed by the commoners were (1) rights of pasturage; (2) of feeding pigs on the Mast; (3) of turbarry or cutting turf; (4) of fuel and marl. These rights they could exercise for about six months in the year. By the Bill of 1851, the rights of the Crown to keep deer in the Forest were extinguished, and as an equivalent it was allowed to enclose 10,000 acres in addition to 6,000 acres which were previously enclosed. The expenses of making and maintaining such enclosures were to be met by the sale of decaying trees, or any other trees not adapted for shipbuilding. The Crown was thus supposed to be possessed of a "rolling power" by which it could continue to enclose and throw open from year to year, always provided that no enclosure was less than 300 acres exclusive of roads.

Though the Crown thus resigned the valuable right of keeping deer, up to the present time only about one-half the land allowed by law to be planted as an equivalent has been actually enclosed and planted, or about 5000 acres; and even in this such difficulties had arisen, and such obstacles were encountered that a Select Committee was appointed in 1868 to inquire into the operations of the Act, and they recommended the allotting to the Crown of certain portions of the forest in fee freed from all common rights, the rest to be left for the unrestricted use of the commoners. Following this, a resolution of the House of Commons in 1871 directed that, pending legislation on the forest, no ornamental timber should be felled, no enclosures made, and, in short, nothing cut save for purposes of thinning existing plantations, executing repairs, and satisfying the fuel rights of the commoners.

Another Select Committee was appointed in 1875, and passed the following resolutions: 1.—That the forest remain open and uninclosed, except to the extent of the Crown's right to plant trees. 2. That the ancient woods, trees, and scenery be carefully preserved. 3. That powers of enclosure be exercised only on the area which has been hitherto taken in at various times. 4. That the Crown retain the power of keeping the 16,000 acres of growing timber and trees at all time under inclosure, but that the rolling power over the open part of the forest should cease. 5. That a nominal quit-rent be charged by the Crown to the commoners for the exercise of the right of common during fence months and winter heyning. These are the resolutions bearing more immediately upon the subject. The Crown claims, and undoubtedly possessed, the right of making successive plantations over the whole 63,000 acres, with the limitation that not more than 16,000 were to be enclosed at any one time. The old woods cover about 5000 acres, which are reduced every year to meet the fuel rights of the commoners. By the above resolutions the valuable rights of the State over between 40,000 and 45,000 acres are extinguished, and the commoners are given the rights of pasturage for twelve months instead of six months, as formerly, for which the State is to receive no compensation, except the nominal quit-rent. As a protest against this spoliation, the Commissioner, in his Report, says: "I submit to your lordships that it cannot be to the interest of the public that new or enlarged private rights should be created over the property of the State."

In the operations of these resolutions of the Select Committees, and not in any mismanagement by Crown Commissioners, are to be found the reasons for the very small returns made from these valuable Crown lands. An Act of Parliament defining and limiting the rights of the commoners, and maintaining the rights of the State would strengthen the hands of the Commissioners, and enable them to realise an income more commensurate with the actual value of the land, whether for agricultural or arboricultural purposes. Or, should a severance take place, the area allotted to the Crown would at once be placed under such scientific treatment as would make it a valuable school for young foresters, and eventually an important addition to the income of the State.

A. J. BURROWS.

THE CLIMBING HYDRANGEA.

(SCHIZOPHRAGMA HYDRANGEOIDES.)

SUBJOINED is a representation of this new Japanese climber, referred to in *THE GARDEN* (p. 237), which, although much reduced in size, affords a good idea of the general aspect of the plant. As will be seen, the leaves are somewhat heart-shaped in outline, and as deeply toothed as those of the common Nettle, and their maximum size appears to be about 4 in. in length and $2\frac{1}{2}$ in. in width. In habit the plant apparently resembles the common Ivy, and, like it, emits throughout the whole length of the branches an abundance of roots, which cling to a wall or the sides of a pot with considerable tenacity. The flowers are white, and, though somewhat small, are produced in such profusion as to give the plant a pretty appearance, accompanied by their small floral leaves. It exists in several collections in this country, and doubtless will soon

The Climbing Hydrangea (*Schizophragma hydrangeoides*).

become common, as it is one of the easiest plants to propagate, merely requiring the branches to be cut into short lengths, pegged to the soil, and treated as cuttings of ordinary hardy perennials. It is probably perfectly hardy, as during the past winter it has been quite frozen. It is now, however, growing vigorously, but, as a rare plant, it necessarily received the protection of a hand-light for the sake of precaution. As a wall or trellis climber it will doubtless become valuable, and if, by cultivation, the flowers become sterile, and thereby the petals or sepals enlarged, as is seen in its congeners, the *Hydrangea* and *Viburnum*, it will, indeed, be a desirable acquisition. It inhabits woody districts at considerable elevations on the mountains of Japan, and, therefore, most probably partial shade will be found to be beneficial to it; but this, and some other points connected with its culture, will doubtless be enlarged upon as the plant becomes better known and appreciated.

W.

INDOOR FRUIT GROWING FOR MARKET.

FORCED STRAWBERRIES.—Strawberry forcing is carried on in the neighbourhood of London to a large extent, and with very profitable results. People within a short distance of the market can gather the fruit when it is required by the salesman, and it can thus be supplied fresh, whereas growers at a distance, who have to pack their fruit and send it by rail on the chance of its being sold, are not in so good a position as far as profits are concerned. Mr. Wilmot, of Isleworth, grows a large quantity of early Strawberries. Sometimes they are placed in the Vineries until active growth has commenced; but, as a rule, they are confined to pits and other places specially provided for them, thereby avoiding the chances of their introducing red spider into the Vineries, which they are very apt to do. Upwards of 20,000 Strawberry plants in pots are forced here every year, and large quantities are planted out in heated pits and frames. For the former purpose the strongest and earliest runners produced by outdoor plants after their fruit has been picked are layered, when they soon take root. They are then carefully lifted with as much earth adhering to their roots as possible, and carried on hand-barrows down to the potting-shed, to be potted into 6-in. pots. The soil used for potting consists of a stiff, loamy character, with a liberal addition of good rotten manure. The plants are potted firmly in the soil, and when that is done they are placed closely together in pits, where they are kept well watered, and have but little air given them until they have commenced to make fresh roots, when the lights are removed and the plants exposed to as much sun and air as possible. Plants treated in this manner are not so good as those layered in small pots in the first instance and potted into larger pots afterwards, but it is probable they pay best, because the labour incurred in keeping from 20,000 to 25,000 small pots well supplied with water during the hottest part of the summer is by no means slight, to say nothing of the labour of filling them with soil and pegging the runners down on them. Portions of the pits in which the plants are placed are supplied with 3-in. hot-water pipes running all round them, and into these compartments the best and earliest plants are put in order that they may be brought gradually on when forcing time arrives. When wet weather sets in in autumn the lights are put on and tilted up at the back, and water is withheld from the plants in order to induce them to ripen their crowns thoroughly, a condition in which lies the principal secret of success. Soon after the commencement of the new year the first batch of plants is plunged in a gentle hotbed, consisting of manure, tan, or leaves, and made up to within 6 in. or 8 in. of the glass. An atmospheric night temperature of from 40° to 45° with a rise of 10° by day is maintained until the plants show flower, when the temperature is gradually increased until the blooms are expanded, at which stage the plants are removed to the Strawberry house to set and ripen their fruit. Water is cautiously applied to the roots until the young fruits are formed, and abundance of air is admitted on every favourable opportunity. When well set the smallest and unshapely fruits are picked off, water is more freely administered, and liquid manure is occasionally applied to assist the swelling of the fruit. When the fruit begins to change colour, a cool, airy temperature is maintained and water is again more sparingly given to the plants, in order to enable them to ripen the berries perfectly and improve their flavour. By the time the first plants have ripened their crop a successional batch, which has been brought on in the same way as the first, is ready to be put into the house, and thus the plants are brought on until the stock is exhausted. Mr. Wilmot's Strawberry house is one of the best of the kind to be met with in market gardens. It is 10 ft. high, and

about the same in width at the bottom, and one side of the roof comes nearly down to the ground, the other, which is short, resting against the back wall. The staging inside consists of shelves arranged like the steps of a stair, and is placed quite close to the glass. Here the plants set and ripen their fruit remarkably well, owing to being subjected to abundance of light, air, and sunshine. Strawberries that are planted out in frames consist of young plants dug up from between the rows of outdoor plantations, when they are forked over and manured in March. As much earth as possible is brought in with the roots, and they are immediately planted about 12 in. apart each way in unheated pits, in which have been put a few feet of warm manure, covered with 1 ft. or 18 in. of good rich soil. After planting, a good watering is given, and the lights are kept rather close until the plants are in flower. The gentle heat of the bed in which these plants are placed quickly promotes root action, and trusses of flowers are soon visible, when they are afterwards treated exactly the same as pot plants. Another batch of plants from the same source is also planted in cold frames without bottom-heat, in order to keep up a succession. These two plantations yield a good supply of fruit after that from the pot plants is exhausted, and before the earliest fruit can be gathered out-of-doors. When in bloom women are employed to pick off the runners and tie a piece of bast, which is supported by a few small sticks, round each plant, in order to afford a better opportunity of watering and keeping the fruit clean.

One grower near London who forces some 9000 plants annually always keeps a plantation out-of-doors on purpose to supply runners, but instead of waiting until these have attained a good size, and layering them in pots (as is generally done), as soon as runners can be had with a pair of good leaves, they are severed from the plants, and dibbled ten or twelve together in 6-in. pots filled with sharp sandy soil; they are then placed in a warm temperature, such as that of a Cucumber or Melon house, where a little shade and moisture can be afforded them. When well rooted, they are shaken out of the pots and potted singly in 3-in. pots, and again placed in a warm house until they have become established, when they are hardened off and placed out-of-doors. Early in August they are potted into their fruiting-pots in good, rich, stiff loam, and placed in an open, sunny situation on a bed of ashes, where they receive plenty of water, and all runners are kept regularly cleared from the plants, which are encouraged to ripen their crowns well before wet weather sets in, a point on which ultimate success greatly depends. Plants which have been forced are also used for that purpose a second time. As soon as the fruit has been gathered from them, they are hardened off, and placed closely together out-of-doors in a shady situation, and are given plenty of water, and otherwise well attended to. In July they are shaken out of their pots and planted in well-prepared ground for a few weeks, where they get well hardened, and make a quantity of new roots close to the stems; they are then taken up, all the old roots cut off, and the stems cleared of dead leaves, &c.; the plants are then placed in their fruiting pots. Thus treated, they produce fruit quite as plentiful and good as that from runners. Strawberries here are placed in cold pits, &c., when bad weather sets in, and batches of about 1000 at a time are taken to Cucumber and Melon houses until they are in bloom, when they are removed to a more airy place to set their fruit; and when fully set they are placed in the large, flat-roofed house, already alluded to, to ripen, which by this time will have been cleared of bedding plants. Sir Charles Napier is the only kind of Strawberry grown here; its fine appearance makes it a good market fruit, and being firm-fleshed, it sustains little injury from travelling.

Another grower, who informed me that he usually gathered about 280 lb. of ripe fruit from 3000 plants in pots, obtains runners from outdoor plants which are layered in small pots filled with garden mould in July. In August they are potted in 6-in. pots in stiff loam, little or no manure being used; by this means rank growth is kept in check, and the crowns ripen thoroughly and never fail to bear good crops of large fruit. The plants are brought into bloom in the Cucumber-houses, and when they have set their fruit, they are taken into the Vineries or similar places to ripen. They are then placed on shelves, not near the glass, as is usually the case, but simply placed on boards laid on the floors of the houses; and, although shaded to a great extent, the fruit, both in colour and flavour, is all that can be desired. Sir Charles Napier is here also the only kind grown, with the exception of a few hundreds of Keen's Seedling to produce a few early fruit. The bulk of the crop is ripened and gathered by the middle of May, as after that time there is no convenience for Strawberries under glass; and, moreover, if kept in houses with other subjects, they are apt to infest them with red spider.

A larger grower at Hammersmith cultivates Strawberries in pots to the extent of 30,000 plants yearly. They are raised from runners layered in 3-in. pots as early as they can be obtained from plants in the open ground, and, when well rooted, are shifted into 6-in. pots. They are then placed in a sunny position, and when wet weather sets in the pots are laid on their sides, a position in which they remain until frost sets in, when they are stacked one on the other in mounds and covered over with ashes or dry litter. Early in February all dead leaves are picked off the plants, and they are placed on the floor of a large lean-to house 12 ft. from the glass. Here they remain until the fruit is gathered, shelves and similar contrivances being entirely dispensed with. Strawberries are not forced here very early in the season, but the fruit is ripened in quantity a month or so before it can be obtained out-of-doors. Strawberries in May fetch from 4s. to 6s. per lb., according to quality, and pay much better than those obtained a month or more earlier, although the latter realise double the price. The house in which Strawberries are grown here was at one time intended for a Vinery; but as it was found that Strawberries succeeded in it so admirably with very little trouble, the idea of planting Vines was abandoned, and it was kept entirely for Callas, Spiræas, Deutzias, &c., during the winter, and Strawberries in spring and early summer. The back wall is planted with Peaches and Nectarines, which yield large crops.

Strawberries in pots have been very successfully grown by Mr. Bennett, of Rabley. One year he fruited a large batch of plants that had been forced the previous year, shaken out and re-potted, and placed on the shelves in the houses. The quantity of fruit obtained from these plants in November and December was something wonderful, and when I paid Mr. Bennett a visit in March he informed me that he was then picking good Strawberries from the same plants, as well as from some that had been grown from runners in the ordinary way the previous summer. Garibaldi is Mr. Bennett's favourite variety for forcing, and in his hands it is certainly superior in every respect to any other kind I have seen used for that purpose. The fruits produced even in the darkest days of winter are of a bright scarlet colour, and on several occasions large fruit of it has been exhibited at the Royal Horticultural Society's meetings at South Kensington, and obtained each time first-class certificates. In the middle of March I have seen shelves of this Strawberry presenting an appearance equal to that often seen in May; the fruit was large and well-coloured, and, contrasted with Keen's Seedling, it had a decided advantage both in appearance and flavour. The pots

were placed about the house wherever it is convenient, on shelves close to the glass, no pans or saucers being employed for placing the pots in, but abundance of water was given whenever the plants required it. Thinning the fruit was never thought of, each plant being required to produce as much as possible, and some of them yielded as many as fifty good Strawberries. The fruit is picked three times a week, packed in punnets, and taken to market. For those produced before Christmas Mr. Bennett obtained from 12s. to 15s. per lb., and during February and March Strawberries of good quality fetch double that price. Strawberries when grown in pots or frames to a large extent are gathered by women every other morning, who place them in small punnets used for that purpose. When all are picked, the punnets are covered with leaves, packed in hampers or boxes, and sent to market. Sometimes the pickers are paid by the day, and at others they receive so much per dozen punnets, according to the crop. When forced plants have ceased bearing, the best are picked out, placed in a sheltered position and kept well supplied with water until a convenient time has arrived for them to be planted out-of-doors in rows between fruit trees or in open quarters on land previously heavily manured and deeply dug, a position in which they seldom fail to yield heavy crops the next season, but, as they seldom bear sufficient to be remunerative the second year, they are dug up and the ground is planted with other crops.

OUTDOOR STRAWBERRIES.—Strawberries are extensively cultivated around London, especially in the neighbourhoods of Isleworth, Acton, Deptford, Chiswick, and Twickenham. In the Fulham Fields the soil is considered to be too light to grow Strawberries well, and therefore scarcely any are grown there, it being considered more profitable to grow other crops that succeed better. Strawberries are often grown under fruit trees, but there are also many open fields devoted to their culture. Those who grow Strawberries for forcing often plant out some of their plants after the fruit has been gathered, but the majority of the Strawberries in market gardens are obtained from runners taken off the outdoor plants after the fruit has been gathered; the best of the runners are then selected and severed from the parent plant with a spade, so as to make them entirely dependent on themselves for support, and thus they are allowed to remain until required for planting, which usually takes place about September or October. The ground to be planted is heavily manured and deeply trenched, or, if it was exceptionally well manured for the previous crop, only a little is used, and sometimes it is only dug one spade deep. The ground, being levelled, is marked off into lines 18 in. apart, lengthwise and crosswise, and the plants, which are dug up with as good balls of earth as possible adhering to their roots, are placed exactly at the intersections of the lines, thus leaving them 18 in. apart each way. In some cases, however, more space than this is allowed. After the first year's crop is gathered, Mr. Dancer, of Chiswick, lifts every fourth row in order to make a pathway to enable the women to gather the fruit off those remaining. These paths are cropped with Lettuces or Coleworts, and thus little or no loss is sustained. Although, as I have stated, Strawberries are largely grown under the partial shade of fruit trees and between rows of fruit bushes, the most favourable situation for them is acknowledged to be an open one. When under fruit trees the distance apart of the plants varies, and depends on circumstances, but 20 in. or 24 in. is the average; one, or at most two rows only, are grown between the bushes. For the first year after planting Lettuces, Turnips, or other dwarf crops are grown between the rows, and even in the winter of after years that space is not unoccupied. No care is exercised in their culture beyond hoeing and mulching, the latter being performed in May or June, or early in spring, and

consists of the common stable manure, which, after it is washed by a shower, is quite clean. A common way of mulching is to scatter the manure all over the field, covering the plants as well as the ground. This being done early in spring, the foliage rises up through the litter fresh and strong. Gathering is done chiefly by women, and in dry weather. The fruits are carefully packed into punnets, which are packed in large baskets for the convenience of waggon transit. After the fruit has been gathered the runners are cut away on either side of the rows, and all refuse taken immediately to the centre of the alleys, which are then dug and cropped. A plantation lasts good for three years, bearing sometimes more or less, according to the land and the dry or wet summers.

Most of the Strawberries grown near London are disposed of for dessert, the chief supply for preserving coming from Kent. At Swanley there are hundreds of acres devoted to Strawberries, the climate and soil being admirably adapted to their growth; I say the soil, because the plants appear to succeed in it so well, but in reality the climate must have the most beneficial effect, or else cultivators, as a rule, are decidedly wrong in their statements with regard to the most suitable soil for Strawberries. It has often been said that a stiff clayey loam of a rich character is indispensable to the perfect culture of the Strawberry; the soil at Swanley is, however, exactly the reverse of this. In some places it may be termed rather solid and stiff, but in the majority of cases it is of a light sandy and remarkably stony character; and in this the plants appear to succeed quite as well, and bear crops equal to those planted in soil of a heavier nature. Indeed, the soil which produces the best crops here is one in which no gardener would think of planting his Strawberries, and yet the yield is enormous. In well-established plantations may be seen as many as 100 good fruits on a single plant. The chief kinds grown are Keen's Seedling, Sir Joseph Paxton, Sir Charles Napier, Late Pine, James Veitch, and Early Crimson Pine. British Queen may be found here and there, but not in very large quantities. The plants are put out in well-manured soil in autumn in rows about 2½ ft. apart and 1½ ft. from plant to plant. Other crops are seldom planted between the rows, the aim being to give the Strawberries the full benefit of the soil. The plough is run between the rows in autumn, which keeps the plants on ridges, thereby keeping the roots well drained. In spring the horse-hoe is used and the ground levelled, after which, in many cases, a slight coat of litter or straw is laid between the plants, in order to prevent the fruit being splashed by the rains. The majority of Strawberries are grown in open fields by themselves, but large quantities are to be found between young Gooseberry or Currant bushes, a position in which they succeed well until the trees get so large as to injure them by their shade. For preserving, Strawberries are not in such great demand as other small fruits; therefore they are often picked with stalks attached to them. They are picked in small baskets, which, when full, are emptied into sieves holding about 24 lb. For each of these the pickers get 5d. in ordinary seasons, and at this rate they make good wages. Even in a year when the crop was not so heavy as usual, one grower informed me that he had sent away nearly 6 tons in one day. Altogether, one year an extensive grower sent away 125 tons of Strawberries to the London markets; and in one day the next year one grower sent away 2500 pecks, the weight of which is nearly 16 tons. All runners are kept regularly cut off the plants, and the ground is kept free from weeds. The best fruit finds its way to the London and other markets, but what are termed squashers, which means the bruised or over-ripe ones, are picked without stalks, put into tubs, and disposed of at some of the jam factories.

Amongst all the Strawberries that come to Covent Garden Myatt's British Queen still retains the foremost position as regards flavour, price, and the quantity sold for dessert purposes. This fact is well known to Strawberry growers, who cultivate it extensively wherever the soil is suitable, but in Kent few of this variety can be seen, the reason assigned being that the Kentish growers sell most of their fruit to the jam manufacturers, and they say their soil is too light for it. The variety called Sir Joseph Paxton created quite a sensation in Covent Garden when it was first introduced, for when unpacked the fruit came out fresh and uninjured, whilst other kinds were much bruised. Fruit of Sir Joseph Paxton resists wet remarkably well; it is fine in form, of a good colour and flavour, and fetches more money in the market than any other kind, British Queen excepted, and it is the chief variety grown in Kent. Goliath, a kind which will endure drought well, is also grown; likewise Comte de Paris and Princess Alice, both early and prolific sorts.

The cost of rooted Strawberry runners is about 5s. per 1000, and if planted in rows $2\frac{1}{2}$ ft. apart each way 7000 plants per acre are required, but if planted in rows $2\frac{3}{4}$ ft. apart and $1\frac{1}{2}$ ft. from plant to plant about 10,500 would be wanted. The best fruit, which is picked in punnets early in the morning and placed in boxes, each of which holds some five dozen punnets, and sent to market early in the day, realises, on an average, 1s. 6d. per lb. If a field of Strawberries be sold to a merchant it realises about £18 or £20 per acre, the purchaser bearing the expense of gathering, &c. Strawberries gathered in tubs and sent to the jam merchants fetch about £25 per ton.

PACKING STRAWBERRIES.—Most of the finest of English-grown Strawberries sold in Covent Garden are packed in shallow punnets, 9 in. or 10 in. in diameter, and in these all, or nearly all, the fruit is exposed to the eye of the purchaser. In the midst of the Strawberry season large quantities of fruit are brought to market in sieves and half-sieves, a sieve containing about seven imperial gallons, but in this case the fruit is principally intended for preserving, and, therefore, its appearance is a matter of less moment than when it is to be used for dessert. There can be no doubt that the broad, shallow English butter-basket, or the Bordeaux basket with a loop handle on the lid, are the best forms of basket to use for transporting Strawberries in quantity either by rail, steamer, or road, and after these the English punnet system is most to be recommended. In the latter case the Strawberries are picked and placed immediately into the punnets by women and children, who carry them when full into the packing-shed, there to be packed in large boxes. A few leaves are scattered in between the layers to keep the fruit moist and cool, and in this way most of the fruiterers and salesmen in Covent Garden are supplied with freshly-gathered Strawberries two or three times a day. An Enfield grower, who annually sends large quantities of the finest Strawberries to Covent Garden, uses what may be termed combination baskets, made in the form of half-sieves, and 10 in. in diameter, by 7 in. in depth. The lid consists of a flat, bottomless basket, over which a cloth is tied by the corners, and this, placed over the basket, forms a well-ventilated covering, and also prevents the fruit from being crushed by any weighty substance falling on the basket from above. Erect cylindrical jars have been recommended in which to pack Strawberries, but the shape is against them, inasmuch as the weight of the upper layers of fruit crushes those below them. Such jars are cool, and the fruit may keep fresh for a longer time placed in these and securely tied down with paper than in shallow baskets, but the weight of the jars themselves is as much or more than that of

the fruit, and this alone would prevent their ever being largely used for packing purposes.

Mr. Gloede, of Hamburg, writing on the subject, says:—"I found from experience that the best material in which to pack Strawberries are the leaves of the green garden Orach (*Atriplex hortensis*); I therefore always sow a certain quantity of Orach seed in March or April, so as to have young leaves available for packing purposes before the crop of Strawberries is fit for use. For packing I use shallow boxes of various sizes which do not hold more than two or three layers of fruit; I line the bottom with Orach leaves and thereon put the Strawberries packed closely together. The first layer being finished, I again use Orach leaves, and so on until the box is full, when I add a good layer of leaves on the top, so that when the cover is put on the boxes will, if necessary, endure hard usage for a couple of days without their contents being in the slightest degree injured. I have frequently sent Strawberries packed in this way both by post and rail over 200 miles, and they have invariably arrived in excellent condition. The sorts which I prefer for such purposes are La Constante, Sir Joseph Paxton, Waltham Seedling, Duke of Edinburgh, The Countess, Early Crimson Pine, Cockscomb, Fairy Queen, Lucas, Dr. Hogg, Unser Fritz, Ascot Pine-apple, and Duc de Magenta, all of which may be picked when quite ripe; whilst President, Frogmore Late Pine, and James Veitch should be gathered a day beforehand. It is useless to attempt sending such soft kinds as Black Prince, Marguerite, Keen's Seedling, Jucunda, &c., however handsome they may be, any distance, as they would be sure to be more or less damaged.

C. W. S.

GARDENING FOR THE WEEK.

Flower Garden.

The charm of a garden is the constantly-recurring freshness which the various plants present at all seasons, but more especially this spring, after the long, dreary winter through which we have just passed. Though many spring-flowering plants have succumbed, those that have survived are thereby rendered the more enjoyable. Amongst them may be named common Violets, red and white Daisies, Crocuses, Primroses, *Anemone apennina*, *Arabis albidia*, and *Scilla sibirica*. These will very shortly be supplemented by *Omphalodes verna*, *Irises*, *Candytufts*, *Hepaticas*, *Gentians*, and others. All of these should be plentiful in every garden. Expense as regards these plants need be no barrier, as they can all be had for a few pence each, and can be transplanted at almost any season. The denser Sedums and Saxifrages are appropriate plants for association with the foregoing, either as undergrowth or as intermediate patches. The following are now very beautiful, viz., *Sedum aureum*, *S. acre elegans*, *S. glaucum*, and *S. lydium*, *Saxifraga rosularis*, *S. hirta*, and *Thymus hirsutus*. The smallest plant of any of these split up and propagated during the summer would make several good patches for next spring time. Lily of the Valley is now starting into vigorous growth, and its flowers will be much improved if the inert surface soil be removed and replaced with fresh loam and well-rotted manure in equal proportions. Beds of *Dicentra spectabilis* and *Spiraea japonica* should be treated in the same way, but it will be necessary to protect these in the event of sharp frost occurring. Mats laid on hooped sticks form the simplest protection for them and other spring flowers of doubtful hardiness. Where spring gardening is not practised, and the beds at liberty, a good deal may now be done to advance the summer bedding and prevent a pressure of work at that inevitably busy season. The arrangements can be completed, the designs marked out, and the hardy and half-hardy plants may be at once planted. Edgings, divisional lines, and groundworks of *Violas*, *Echeverias*, *Sempervivums*, *Saxifrages*, *Sedums*, *Menthas*, &c., can all now be planted with safety, and very shortly *Calceolarias* and *Verbenas* may follow. Tastes differ both as to arrangement of colours and designs; I shall therefore say nothing on either of these points, except that there should never be a preponderance of glaring colours, of which the eye soon tires, and the designs should be of the simplest kind; intricate designs are never effective. Autumn-sown annuals that have survived the frost may now be thinned out; the plants are sturdier, and flower better than if left too thick. Sow in the open ground Sweet Peas, Mignonette, Candytufts, *Eschscholtzias*,

Larkspurs, and Clarkias, and prick out those sown in frames as soon as they are fit to handle. Bedding plants have driven annuals for summer embellishment out of our flower gardens, and though this is to be regretted it cannot be wondered at, seeing that bedding plants are so much more lasting and amenable to manipulation. Still, there is room for both in most gardens—the bedding plants for the parterre, and the annuals for the mixed borders, supplementary to the herbaceous plants, a purpose for which they are every way adapted. Shrub planting, pruning, hedge clipping, and all other extraneous work should now be completed, as each week will bring its own work that must be done, such as mowing and rolling lawns, sweeping, weeding, and rolling walks, and planting out bedding plants.

Auriculas.—Exhibitors now of these will have an anxious time of it, as all the trusses of flowers are showing themselves, and the question arises as to whether certain flowers will be in perfection at the time required. No definite instructions on this point can be laid down for those who have not had experience in such matters; suffice it to say, however, that, as a rule, selfs are in good condition early, and that they do not stand so well as the best green, grey, or white-edged flowers. There are exceptions, however, as one of the latest Auriculas to flower is Duke of Argyll, a fine crimson self, and some of the edged flowers lose their character in a few days after the zenith of their beauty has been reached. If it be intended to push forward any late trusses, the plants may be placed in a warm house, near the glass, and air must be admitted rather freely by day, with a little at night. The Auricula shows are fast approaching, and as many growers at long distances off may want to exhibit, but are deterred from doing so owing to the expense, I may mention that if such persons would turn the plants out of their pots, and wrap the balls round with old shading tightly, they might be packed into very small boxes. I have, indeed, seen an exhibitor carrying a box in each hand, in each of which there were thirty plants—as many as most amateurs would be able to exhibit. The societies provide pots and Moss for surcising them.

Carnations and Picotees.—These seem more stubborn to start into growth this year than usual; when they do fairly start, they will probably make up for lost time. Look over the plants and remove decayed leaves, also weeds which will be sure to grow in the fresh compost. Keep all tender sorts under the protection of cold frames as long as is convenient to do so. If cuttings of Perpetual-flowering Carnations have not yet been put in, no time ought to be lost in seeing that this is done. Those who are desirous of having a large stock of plants should put in the small side growths as soon as they are large enough for that purpose. If these be placed under a close glass light in the propagating house, not 5 per cent. will fail to strike root. Cuttings put in early and now well rooted should be potted off singly in small pots, setting the pots in a warm, rather close place, to induce the formation of fresh roots; afterwards place them in a cold frame.

Hollyhocks.—These should be grown much more extensively than they now are. Seeds from the best sorts may now be sown in the open air if there be no glass lights or frames available, but they will germinate more freely in a gentle hotbed, although they must not be coddled under glass after they are aboveground. Plants raised in this way will flower well next year. See that no time is lost in getting all named sorts planted out, using the precautions previously recommended.

Pansies.—These are even more deserving of attention than the Hollyhock, as they are attacked by no disease that cannot be easily combated. Plants in pots are now making a charming display, and if the leaves have been kept free from mildew and greenfly, a continuation of fine flowers may be expected. When the flowers begin to fall off in quantity, as they will do in time, pick all of them off, surface dress with rich soil, and on this peg the shoots down; this will produce renewed vigour, and perfect flowers will be the result.

Hardy Primulas in Pots.—Sparrows are very destructive to these when planted outdoors. We have hundreds of Primroses and Polyanthus planted out, and it is disheartening to see the flowerbuds picked off and dropped on the ground in thousands before they open. Grown in cold frames, the finer forms of Primrose rival even the Auricula and laced Polyanthus. They require but little attention, but that must not be denied them; they must have free ventilation, plenty of water, and the leaves kept free from red spider and greenfly. Plants of *P. nivalis* are now masses of bloom, which is admired by every one. We place the plants under a north wall when they go out of flower, and there they make free, healthy growth.

Tulips.—These everywhere have made slow, but healthy growth. I wish we could cover the beds with glass lights, to prevent rain and frost from injuring the leaves, and also to save the rising flowers from injury. We would rather, as yet, use them for the Carnations. In

order to grow the finer kinds of Tulips well they ought to have a glass protection. The canvas shades should now be used on cold nights.—J. DOUGLAS.

Parks and Open Spaces.

Plants for Out-of-the-way Corners.—In public parks, especially where they are extensive, will always be found, comparatively speaking, neglected corners in out-of-the-way places, where, from some cause or other, it is both impracticable and unadvisable to carry out the usual routine work of the more conspicuous portions. This is particularly the case under large trees (where few plants will thrive), on banks, &c. These positions may be considerably improved by the addition of plants which require but little attention. One of the most useful for this purpose is the Giant Cow Parsnip (*Heracleum giganteum*), a plant which produces noble umbrageous foliage and bears immense umbels of greenish-white flowers on stout stems, from 8 ft. to 10 ft. in height. It soon establishes itself, and care could be taken that it does not seed too freely, as it would cause much trouble. Altogether it is a most desirable plant, and wonderfully effective. Thistles (*Carduus*) are very handsome subjects for the same purpose, some of the varieties reproducing themselves freely. Galega officinalis should be found in every wild or neglected garden, as a few plants of it placed at intervals of 6 ft. or 9 ft. apart will soon establish themselves over a large area, as they seed profusely. The foliage is extremely elegant, the Pea-shaped flowers (pale blue and white) exceedingly pretty, and they continue in perfection for a considerable time. The annual Sunflowers are most desirable. A few seeds of them sown in the most open places between trees and shrubs produce an effective show during the summer and autumn months. Evening Primroses (*Oenothera*) and Marigolds produce a profusion of bright, yellow flowers, and require no further attention than an occasional weeding. *Phytolacca decandra* is a hardy perennial, growing some 4 ft. in height, and bearing very handsome and peculiar spikes of dark crimson fruit. Centaureas, belonging to the hardy section, are particularly attractive, some having golden-yellow ball-like flowers, others blue, purple, &c., and all of them are of easy cultivation. Verbascums are also well adapted for shrubberies, and produce a profusion of singular Orchid-shaped flowers of various rich shades. Among plants that are more suitable for the front rank in shrubbery borders may be mentioned the following: *Nasturtiums*, *Antirrhinums*, *Canterbury Bells*, *Columbines*, *Foxgloves*, *Geums*, *Pyrethrums*, *Rockets*, *Sweet Williams*, *Valerian*, *Polemoniums*, *Gladiuncs*, *Lupins*, *Wallflowers*, *Polyanthuses*, *Pansies*, *Saponarias*, *Mignonette*, &c. These are all extremely varied and beautiful, and require but little attention, reproducing themselves freely, and yielding a round of flower extending over several months. Beets, Fennels, and *Acanthus* are most useful in the way of furnishing foliage, as are also *Artemisias*. With such plants as these, many a nook which is now neglected might be made attractive. The whole of the above require only the simplest treatment, and will well repay those who will give them a trial.

Annuals, &c., as Substitutes for Bedding Plants.—Although annuals do not, as a rule, last long in flower, there are some which may worthily rank with bedding plants, and amongst these may be mentioned the following: *Asters*, *Balsams*, *Heli-chrysums*, *Nasturtiums*, *Ten-week Stocks*, *Phlox Drummondii*, *Portulacas*, *Tagetes*, *Sanvitalias*, and *Zinnias*, as flowering plants, and *Beets*, *Amarantuses*, *Perilla*, *Artemisias*, *Tobacco*, *Ice plants*, *Solanums*, *Ricinus*, and *Salvia argentea* as fine foliage plants. There are also a few perennials, biennials, and annuals which may be raised from seed, but which are usually struck from cuttings in order to preserve some special character, viz., *Ageratums*, *Verbenas*, *Lobelias*, *Petunias*, *Cannas*, *Chamepseudes*, and *Pyrethrums*; all these are beautiful as regards either foliage or flowers, and, if carefully used, may be induced to produce a display almost equal to that yielded by our most favoured bedding plants. With the exception of *Sanvitalia* and *Beets*, the whole may be raised in pots on a slight bottom heat, and as soon as they are fairly out of the ground they should be placed in a greenhouse for a few days to harden off. A cold frame having been prepared with rich soil, the flowering section, with the exception of *Ageratums*, *Balsams*, *Lobelias*, *Petunias*, *Phloxes*, *Portulacas*, and *Verbenas*, which should be pricked off in pots and kept in moderate heat close to the glass, should be pricked off about 3 in. or 4 in. apart. The whole of the fine-foliaged section should be put into pots, pans, or boxes, and retained in heat. A knowledge of the heights and colours only is then required to make a grand display. A moist, warm day should, if possible, be chosen to put them in the open ground, and if taken up with balls of earth they will be sure to succeed. *Sanvitalia* and *Beets* may be sown where they are required to stand and thinned out where necessary. *Pyrethrums*, *Petunias*, *Lobelias*, *Ageratums*, *Cannas*, and *Chamepseudes* should, to have them in good condition, be sown as early as possible.

Trees and Shrubs transplanted during the winter should be carefully watched in regard to watering. Many failures are attributable to neglect in this respect. I would recommend, except in wet, heavy soils, that as soon as the buds show signs of expansion water be given on the least appearance of shrivelling of either bark or buds, and in dry weather watering should be continued until the foliage is fully developed. In many cases a weak mixture of manure water may be given with advantage.

Grass Seeds sown during March will soon be fairly above ground, and should be well rolled as often as the weather will permit. As soon as the Grass is sufficiently grown the mowing machine or scythe should be used; this cannot be done too soon or too often, as some Grasses, and also weeds, will be found to grow rapidly, and will, if allowed to remain, destroy some of the most desirable kinds of Grass.—CHARLES DENNIS.

Conservatory.

Where conservatories of large size are kept fully furnished with flowering plants all through the season, it not only requires several other houses or pits to bring the plants into flower in succession, but also others into which they can be moved after blooming. When conservatories are kept, as they generally are, at a much higher temperature than ordinary greenhouses, and the structures into which the plants have to be moved after blooming are insufficient for the purpose, the plants often receive a check which much interferes with the season's growth. All such subjects as Genistas, Acacias, Daphnes, and even *Deutzia gracilis*, that have been pushed on in heat, should, immediately after blooming, be placed where growth, already begun to be made, can go on unchecked. Any plants of these descriptions that require more root-room should at once be potted, for, in their case, the flowering capabilities for next winter will, in a great measure, be proportionate to the growth which they make through the summer, and any that will bear cutting back should be operated on freely, for with plants such as those just named, it is usually much better to have a good number of a compact, useful size than to allow them to get too large, as, in that case, they often have a bare-stemmed and unsightly appearance. *Azaleas* and *Camellias* taken from the conservatory should at once be placed under conditions favourable to their growth; the *Camellias* should be kept close, and should have a night temperature of 50° or 55°, and higher in the daytime, according to the weather. There should be plenty of moisture in the atmosphere and at their roots, and they should be shaded from bright sunshine. *Azaleas* thus started into growth should be kept scrupulously clean from their worst enemy—thrips; but in their case, little, if any, shade is required or should be used, as it induces a soft, weak condition of the leaves, rendering them more liable to suffer from the attacks of insects and less capable of bearing any application for their destruction. Cyclamens done flowering should, at once be placed in a house or pit where the atmosphere can be kept a little close, with plenty of light, but slightly shaded from the sun; these are also liable through the spring months to get infested with green fly and red spider, which, confining themselves almost exclusively to the undersides of the leaves, frequently go unobserved until the foliage is very much injured, the result of which is that it dwindles away through the summer, and the roots get into a stunted, hard state, which prevents their afterwards growing and flowering satisfactorily. Where means exist, and the hints that have been given are followed for keeping back a few of the latest-flowering kinds of *Camellias*, these will be found very useful in the conservatory during this month along with *Epacris*, *Boronia*, *Eriostemons*, *Azaleas*, *Rhododendrons*, the latest batch of *Hyacinths*, *Tulips*, *Lily of the Valley*, forced *Roses*, *Cinerarias*, &c. As the sun's power increases, there will be still more need for attending to shading, or the flowers of most plants will be of comparatively short duration.

Climbers that were cut back during the winter, and that have now commenced growth, must have regular attention in the way of training. Those possessing a twining habit require constant care in this matter, otherwise the shoots get interlaced to such an extent that it is impossible afterwards to get them disentangled, and the young growth of all such plants as these is generally so tender as to scarcely admit of being untwined from anything that it lays hold of without stopping further extension. Plants of this description, either grown in pots, tubs, or planted out in borders, where the root space is limited, will, in most cases, require the assistance of manure water. It is, however, of little use applying this unless growth is actually in progress; for, if given at other times, the fertilising elements which it contains get washed away by the usual waterings, and do no good. In structures of this description the use of ordinary manure water is not admissible, from its offensive odour, but if made from guano, with a little soil, and applied early in the morning, that objection will be obviated, and in places where nothing of the kind can be employed, Standen's manure dusted on the surface of the pots, tubs, or beds, where it gets washed into the soil with the ordinary waterings, will be found most effectual.

Greenhouse.

Hard-wooded Plants.—Whatever potting remains to be done should be finished forthwith; not only is this necessary to make way for other work, but it will be much more conducive to the well-being of the plants. The roots of such as were potted earlier will now be beginning to take to the new soil; they may be gradually inured to a fuller admission of air, but during this month it must be given at the sides of the house and with caution, for, although on some days the weather is favourable, on others it is not, and it should always be remembered that plants grown under glass are, for the most part, indigenous to countries considerably warmer than our own, and that consequently during our cold spring weather they are not able to bear exposure to anything in the shape of a direct draught. Young plants that have been potted should now be well tied out, with a view to laying the groundwork of future specimens, determining the shape by their natural habit, or that which they would assume if undisturbed, and stopping and bending lower down the strongest shoots, so as to equalise the growth. The whole stock, large and small, should now be gone over every morning in order to ascertain what requires water, as any inattention in this matter is much more injurious in its effects in the case of hard-wooded than in that of soft-growing plants.

Tuberous-rooted Begonias.—A stock of these should be grown in all places, large or small, on account of their being so useful in many ways. Roots of them started some time ago will now have made some progress, and should be furnished with root-room proportionate to the size of the bulbs. They will thrive under ordinary greenhouse temperature, but will come on faster if kept a little warmer. Any remaining bulbs that may yet be in a dry state should immediately be started; they will come into flower later in the season.

Calceolarias.—The herbaceous varieties will now be growing apace, and should be well attended to with manure water; they are gross feeders, and the advancing flower-spikes will be much benefited by it. They should be kept in a temperature of 45° at night. There are no plants that require more care as to keeping them free from aphides, for if these be once allowed to get ahead, it takes a severer application of Tobacco to kill them than the blooms will bear. The shrubby kinds are equally deserving of cultivation as the softer sorts, although their flowers may not be so conspicuous. There are few more useful subjects for general decoration than the old *C. anæa floribunda*. It is serviceable in the shape of small plants, such as are grown for the London market; but so managed it is insignificant compared with the character which it assumes when grown on for years and regularly cut back each season after flowering, something like a *Pelargonium*, part of the soil being removed, and the plant re-potted similarly. In this way I have kept these shrubby *Calceolarias* on for a number of years until they were from 2 ft. to 2½ ft. through, forming dense masses of golden-yellow, which continued in perfection in the conservatory for weeks after the spring-flowering plants were mostly over, a time at which they are very acceptable. Any of the stout-habited, dark-flowered kinds are suitable for growing in the same way. The treatment which they want at this time of the year is such as that which answers for the herbaceous sorts.

Cinerarias and Primulas.—Those who intend to save seeds of these should select the best marked forms as seed bearers. In the case of the *Primulas* they should be set on a dry, airy shelf, where they will get plenty of light, choosing plants that have not been weakened through early flowering, as they will not produce nearly so much seed as those that have only bloomed recently. With *Cinerarias* it is necessary to keep the colours separate. My practice is to put the best forms and colours of red, and also of blue, as well as the white grounds with red tips, each by themselves in small frames from the time they come into flower, selecting for the purpose the latest bloomers. Thus treated, these three colours will produce plenty of variety, including the many shades of purple and violet; but only by keeping them apart can a preponderance of the blues and purples of different shades be avoided. A little more *Cineraria* seed may again be sown towards the end of the month, and the plants from the first sowing must be treated so as to prevent their being drawn up weakly. A little *Primula* seed should also be sown to come into flower before Christmas. Double *Primulas* may now be propagated by means of cuttings kept a little warm, but not so much confined, or they are liable to damp. They are not nearly so effective for decorative purposes as the single varieties, but where flowers are much in request for cutting the double kinds are a great deal the best, as they last longer than the single ones.

Berry-bearing Solanums that are to be planted out during the summer, a system of treatment which, when the plants are managed in accordance with their requirements, I have found to be better and entail less labour than keeping them in pots; but to suc-

ceed in having the berries coloured early enough in the autumn they must be put out at once; they will stand much more hard weather than is generally supposed. I have never seen any frost after this time that will injure them in a fairly sheltered position, such as that ordinarily selected for their summer quarters. The advantages of planting out over growing in pots are, a denser habit of growth, more profuse and better coloured foliage, with much less trouble in keeping the plants free from red spider, and supplied with water.

Orchids.

The house in which the cooler section of Orchids are grown will now be getting gay with the flowers of *Odontoglossums*, *Masdevallias*, and other spring-blooming, cool house species. White or nearly white flowers like those which most of these *Odontoglossums* bear are very much more liable to show the effects of condensed moisture by becoming spotted than flowers of other colours; therefore, to keep the bloom fresh as long as possible, no more atmospheric moisture should be maintained than is necessary for the well-being of the many subjects that will now be making growth. Plants that have been affected the preceding season by that diminutive little pest the yellow thrips must be looked to, as increased solar heat will cause them to breed fast, and, if left unchecked, they not only make the foliage unsightly, but the injury which they cause to the young leaves in a partially developed condition has a serious effect upon the strength of the plants, for leaves that have been so damaged in their young state do not retain their vitality for the allotted time, and with these plants, as with all others, a premature loss of leaf has a weakening influence upon the whole plant proportionate to the extent of the injury inflicted. Whatever potting in this department remains to be done should be at once carried out, and the pots of those that do not require more root room ought to be surfaced with a little fresh material.—T. BAINES.

ANSWERS TO CORRESPONDENTS.

Cool Orchids.—Having greenhouse and forcing house attached, I would be obliged if you could give me the names of a couple of dozen Orchids that I could grow without a great amount of heat.—E. F. S.—*Bryophyllum calycinum*, *A. K.*—*Cornus Mas* (the Cornelian Cherry). *H. A.*—*Dendrobium densiflorum* album. Of this there are several varieties, the largest and best being named *Schredleri*. *Miss T.*—*Sisyrinchium grandiflorum*. *W. L. A.*—*Tropaeolum tricolorum*, certainly not *T. azureum*.

Camellia Sports.—I send you herewith two blooms from the same tree of the *Camellia Laxia*, one of which has the usual cherry-rose tinge and stripe on a white ground, and the other is a deeper cherry-rose self-coloured sport, and shall be glad if any of your readers would inform me whether to their knowledge a similar sport has occurred elsewhere in the case of the above-named variety. This is the first year during which it has appeared with me, and therefore it is fair to conclude that it is likely to be permanent, and may be worth propagating.—T. B.

Vines.—*Sub.*—If your Vines be as bad as you describe, your best plan will be to take them up and plant new ones.

Wellingtonia.—I have a well-grown plant about 30 ft. high that the frost has severely injured, the points of the shoots being dead and an ugly brown coat 9 in. to 12 in. How should the tree be treated? Shall I cut back all over?—W. B. [Yes; cut the dead tops off at once.]

Questions.

Vines in Greenhouses.—What am I to do with a Vine, a Black Hamburgh. It is ten years old, yet the stem is no thicker than a man's finger, and it has borne no fruit. The shoots are weak, and it looks starved, and yet it has good manure and manure water, and been closely pruned last year. The roots are in a bed outside a small greenhouse, and the two branches are trained inside and supported by the supports of a span-roof. I must add that the greenhouse is small and full of flowering plants, and are best applied to it nearly all the winter. I should like a few bunches of Grapes for effect if not for enjoyment. What is to be done?—WETTERDEN.

Zinc Labels.—Are these injurious to Orchids? A writer on these plants, speaking of wire, recommends copper, because, he says, any other metal is probably injurious to the plants.—W. B.

Androsace helvetica.—I have a large cushion of this in a pot which I planted two years ago in Cocoa-nut fibre refuse mixed with sand, and I find now that the roots have penetrated into the plunging material. Now, as I want to save seed from it, I should not like to do anything which would interfere with the formation of flowers, but I am afraid the roots, rambling in the Cocoa-nut fibre, will, in themselves, be a cause of preventing a free production of blooms, and I think this must have been the cause of its not having flowered last year, while the year before, when the roots were confined in a pot, there was a good show of bloom. What had I best do to attain my object?—E. H.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 8.

The show of plants on this occasion was an exceedingly good one, many of the leading nurserymen contributing attractive groups, but the special feature of this exhibition was seedling *Amaryllises*, from Messrs. Veitch & Sons, Chelsea, consisting of about 150 plants of unusual excellence. Amongst them were introduced, with good effect, healthy dwarf Palms, Ferns, and similar plants. A group of Orchids, from Sir Trevor Lawrence, also attracted great attention.

First-class Certificates were awarded as follows:—

Dendrobium Brymerianum (Veitch & Sons).—A species with golden-yellow flowers and bearded lip; previously described in THE GARDEN.

Amaryllis Duke of Connaught (Veitch & Sons).—A scarlet-flowered kind, with broad, round petals of remarkable substance, and very smooth.

Chionodoxa Lucilliae (Barr and Sugden).—A charming, hardy, Scilla-like plant, having starry flowers, white and tipped with blue.

Cœlogyne ocellata maxima (Williams).—A free-blooming kind, with white yellow-barred flowers set on long, graceful, arched spikes.

Masdevallia bella (Sir Trevor Lawrence).—A fine variety of the *Chimara* type, having large and singular blossoms, which, in the case of plants grown in baskets, come through their meshes, as *M. Chimara* often does.

Dendrobium crassinode album (Sir Trevor Lawrence).—A variety having finely-formed flowers, of snowy-whiteness, with a well-defined golden-yellow throat.

Cultural Commendations were awarded to Mr. Green, gardener to Sir G. M. Macleay, Reigate, for a cut spike of *Mackaya bella*, a fine old greenhouse climber rarely met with, and bearing Bougainvillea-like blossoms of a delicate lavender veined with crimson. To Mr. Boller for a singular *Echinocactus* named *E. myriostigma*; and to Mr. Woodbridge, for a fine specimen of *Cyrtopodium punctatum*.

Medals were awarded as follows:—Large gold Banksian to Messrs. Veitch & Sons for their group of seedling *Amaryllises*; small gold Banksian to Mr. Williams for a similar exhibition; a silver Banksian to Mr. Barr & Sugden for cut blooms of *Narcissi*; a silver-gilt Flora to Mr. Bull for a group of new and rare plants, Orchids, &c.; large gold Banksian to Sir Trevor Lawrence for a group of Orchids; silver-gilt Flora to Messrs. Paul & Sons, Cheshunt, for a collection of pot Roses; and a small silver Banksian was recommended to be given to Mr. Woodbridge for his plant of *Cyrtopodium punctatum*.

Miscellaneous Subjects.—Mr. William Bull showed an attractive group of new and rare plants, Orchids, &c. Among them were good plants of *Dracena Goldieana*, *Curculigo recurvata striata*, *Kentia Belmoreana*, *Encelphalaris villosus*, *Epacris onosemiflora*, *fl. nivalis* (in good condition), a little Alpine *Azalea* named *A. balsameiflora*, *Croton Dornmannianum*, and *Hemanthus cinnabarinus*. With these were associated *Cœlogyne ocellata*, *Dendrobium Falconeri*, *D. crassinode Barberianum*, *D. Wardianum*, *Lady's-slipper*, *Odontoglossum gloriosum*, *O. triumphans*, *O. odoratum*, *O. Pescatorei*, *O. crispum*, *O. cirrhosum*, and *O. Halli*; also *Masdevallia ignea* and *Harrayana violacea*, and *Cymbidium Lowianum* and *eburneum*. Among Orchids shown by Sir Trevor Lawrence were *Dendrobium Jamesianum*, bearing twenty flowers; *D. thyrsiflorum*, with a dozen pendulous trusses; *D. Devonianum*, bearing a pseudo-bulb upwards of 3 ft. long, and beset with large fringed blossoms; the yellow *Oncidium concolor*, with from fifteen to twenty graceful spikes of unusually large blossoms; also fine examples of the brilliant *Masde-*

vallia Harryana, and a fine purple variety of it named *M. H. cœru*lescens; *Cœlogyne corymbosa*, the curious *Cœlia Baucaria*, *Odontoglossum cirrhosum*, *O. triumphans*, *Lady's-slippers*, and *Phalenopsis*. Mr. B. S. Williams, Holloway, showed a group of plants, consisting of *Sobralia aurantiaca*, *Vanda tricolor superba*, *V. suavis*, *Odontoglossum triumphans*, *O. cirrhosum*, and *Pescatorei*; also *Lycaste Skinneri* and *Cymbidium eburneum*. With these were associated *Crotos variegata* and *Williamsi*, fine-leaved *Dracenas*, *Yucca filamentosa dispersa*, the curious *Sarracenia psittacina* in flower, a fine panful of *Dionaea muscipula*, and well-flowered plants of *Anthurium Scherzerianum*. The same exhibitor also showed a rich and varied group of *Amaryllids*. A fine group of pot *Roses* came from Messrs. Paul & Sons, Old Nurseries, Cheshunt. Among them were *La France*, *François Michelin*, *Madame Lacharme*, *Catherine Mermet*, *Comtesse de Serenyi*, and *Royal Standard*, all in good condition; also cut blooms of *Maréchal Niel* and others. Messrs. Barr & Sugden exhibited cut blooms of *Daffodils*, among which were the following kinds, viz., the double *Florence Daffodil*, *Narcissus Humei*, *N. Pseudo-Narcissus Leedsii*, *N. obvallaris*, *N. o. maximus*, *N. incomparabilis albus Leedsii*, *N. cernuus*, *N. nanus*, *N. lobularis*, *N. Telemionius*, *N. bicolor of Florence*, and *N. lorifolius of Leeds*. The same exhibitors also showed a box of cut blooms of *Hellebores*. A group from Messrs. Charles Lee & Sons, Hammersmith, contained well-flowered *Indian* and *Ghent Azaleas*, *Rhododendrons*, *Amaryllises*, & *Spiræas*, intermixed with *Palms* and other fine-leaved plants. Messrs. Osborn & Sons, Fulham, had a group of plants consisting of *Azaleas*, *Anthuriums*, *Hyacinths*, *Arum Lilies*, and fine-foliaged plants; and Mr. Aldous, South Kensington, showed a group of *Hydrangeas*, *Azaleas*, *Pelargoniums*, *Ferns*, and similar decorative plants. Mr. Parker, Tooting, contributed hardy plants, amongst which were the double-flowered variety of *Primula acutis lilacina*, a suitable sort either for pot or border culture; also blue *Scillas*, *Floricas*, and *Saxifraga diapiensoides*, a dwarf kind with white flowers, like those of *S. Burseriana*. Mr. Dean, Bedford, exhibited a group of *Primroses*, among which were single and double kinds possessing various colours, such as purple, white, crimson, yellow, mauve, lilac, and intermediate shades. Large-flowered blue *Aubrietias* and brilliantly-flowered *Polyanthuses* also came from the same grower. Mr. Wiggins, gardener to H. Little, Esq., Hillingdon, showed *Cinerarias* very dwarf in habit, and having well-formed, finely-coloured flowers. From Chiswick came remarkable plants of *Hebelcolum inanthum*, with large bronzy leaves and *Ageratum*-like heads of blossom; also well-grown examples of *Primula rosea* and *P. denticulata*. Messrs. Veitch & Sons showed standard plants of *Lilac Charles X.*, having clean stems 4 ft. high, surmounted by large, round heads of blossom; also a fine panful of the sweet-scented Australian *Boronia megastigma*. Messrs. Cutbush & Sons, Highgate, exhibited several boxes of cut blooms of *Camellias*, among which we noted large flowers of *reticulata*, the well-known kind called *Chandleri*, and many of the best white and striped kinds. The same firm also showed a group of *Epacris*, among which were plants having white, pink, and rose flowers, and various intermediate shades of these colours. Mr. Green showed blooms of *Abutilon venosum*, a kind with palmate leaves and large crimson-striped flowers of large size. Mr. Howe, gardener to A. Smith, Esq., Streatham, showed fine blooms of *Rhododendron Nuttalli*, and Mr. Heims, gardener to A. Philbrick, Esq., fine blooms of *Odontoglossum nebulosum parvum superbum*. Mr. Wiggins furnished, amongst *Cinerarias*, *Dolly Little* and *Rosa Little*, two dwarf kinds, the former having purple flowers with white centres, and the latter white flowers edged with blue. Mr. Hovey again showed *Camellia* blooms, consisting of kinds already alluded to in THE GARDEN. Mr. Hunter, Lambton Castle, contributed plants of *Valeriana Phu*. The Rev. J. T. Boscawen showed a plant of the white-flowered *Rhododendron* Mrs. Townshend Boscawen.

The prizes offered for new *Amaryllises* brought but little competition, the only prize awarded being to Mr. Speed, Chatsworth, for a plant bearing a remarkably strong spike of scarlet blossoms with white centres—six in number.

AMERICAN NOTES.

A Useful Turf-cutter.—For making a small lawn it is far more expeditious and satisfactory in all respects to lay down turf, if it can be procured, than to sow seeds, and even where the surface is too large to be turfed sods are almost indispensable for those portions bordering upon roads or paths, as well as for the outlines of such beds as may be made in it. The usual method of cutting turf is to lay down a board of the desired width; the operator, while standing upon the board, cuts down on each side of it with a sharp spade; then, lifting an end of the strip with the spade, one person rolls the

turf, while another, with the spade, cuts away the roots that penetrate the soil below. A roll made of a strip 12 ft. long is as large as two persons can conveniently handle. A new turf-cutter, made as follows, has been found to be an improvement on the old method:—The body of the cutter (A) is a block of hard wood, 10 in. thick, 12 in. wide, and 3 ft. long; the cutter (B) is a strip of $\frac{1}{4}$ -in. iron, 3 in. wide, and bent at the ends at right angles to fit the block, as shown in the engraving; one side of this is hammered thin and ground to an edge, not only along the horizontal part, but for 3 in. or 4 in. on

Home-made Turf-cutter.

the turn-up portions. This is then firmly bolted to the block, the distance below it being governed by the thickness at which the turf is to be cut. The lower part of the block, immediately above the knife, is hollowed out to allow the turf to pass easily between the block and the cutter. There is, of course, an arrangement for hitching a horse to it, and a couple of handles, like plough handles, are attached to allow the implement to be guided. The block may be weighted, if necessary, to keep it down.

India-rubber Floor-wipers for Greenhouse or Dairy Floors.—There is an article called the "window-wiper," which is coming into very general use in cities. It is a strip of vulcanised India-rubber, about $\frac{1}{2}$ in. thick or less, fastened upon the edge of a

Stone Floor-wiper.

flat piece of wood, and projecting from it as an edge, as seen in the engraving. This is used to clean windows, and being wiped over wet glass leaves it clean and dry. The effect of a similar use of the wiper, or of a stronger one adapted to the purpose, upon wet floors, is to sweep and wipe the floor, leaving it clean and nearly dry, much better and more rapidly than any mop or broom, or both combined can do. In fact, in greenhouses, dairies, and kitchens, when once tried, it becomes almost indispensable, and upon cement floors, where water can be freely used, it is efficient in its action, both cleansing and drying the floor very rapidly.

An Improved Road-scraper.—If the operation of an ordinary road-scraper be observed, it will be seen that it is faulty in one important point, viz., that it leaves the hollows as it finds them, if, indeed, it does not scrape them out deeper. It simply smooths the surface, but does not level it. By the simple addition of runners

An Improved Road-scraper.

by which it is kept from falling into the hollows, it will draw earth into them instead of scooping them out. The runners are raised 1 in. or 2 in. above the bottom of the scraper. It will thus scrape up the loose soft earth and deposit it where needed, that is, in the hollows, thus levelling as well as smoothing the surface. The form of the improved scraper is represented in the annexed engraving.—"American Agriculturist."

"This is an art
Which does mend Nature: chance it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

TOMATOES EVERY MONTH IN THE YEAR.

HAVING been very successful in the cultivation of Tomatoes, allow me to give an account of my mode of treatment, and to show how Tomatoes may be obtained every month in the year. To the main crop I have a house exclusively devoted. It is span-roofed, 45 ft. long and 11 ft. wide, and runs from east to west, but it would have been better from north to south, as in that way more light and sunshine are secured. In the house in question, though I plant the largest plants on the north border, those on the south side soon shade them. I sow the seed the first week in January, and pot off the seedlings when fit to handle. I plant early in March, and from this house I have sent Tomatoes to market from the first week in May, 1878, to the first week in April, 1879. I pulled the old plants up in March, when I planted the fresh crop; but I put the green Tomatoes in a box, covering them up, and they coloured satisfactorily. The soil for Tomatoes should not be over-rich at planting-time; when fairly started they should have a good dressing of manure; but be careful as regards the use of fresh stable litter. They require liberal watering, and as soon as I see the first fruits setting, I give them liquid manure.

In the house above alluded to I have them planted 2 ft. apart. One row of Trophy is planted all round the house, and when the plants get up to the wires they are stopped and the next shoots are trained over the trellis-work. Then there is a row of the old Red, the plants of which run up a stick 5 ft., and are kept to single stems. Trophy is the principal cropper, and it is astonishing what a quantity of fruit can be got off a single stem; the plants fruit at every alternate joint, beginning about 1 ft. from the bottom. The front row on the north border is planted so that the plants do not face the back row of Trophy. Although Trophy is the kind upon which I most depend, its fruit being heavy—a great consideration where fruit is sold by weight and the plants abundant bearers—still, I would recommend your readers not to plant many of it, as it is not every one who can fruit it at first; but, after watching its peculiarities the first year, more of it may be planted. In the house just described I have had plenty of fruit, each of which weighed over 1 lb., and they were almost as round as an Apple. I am very careful as regards seed saving. Tomatoes planted here in March are now in flower, and by the first week in May fruit will be ripe. I should state that the whole of our Tomatoes are grown in heated houses.

In our late Vinery, which is 80 ft. long, I have a row 18 in. plant from plant on the back wall; these I fruit in the shape of single stems. I do not, however, expect these to do much good this season, as the Vines are now three parts up the rafters. Nevertheless, the Tomato plants being strong, may get up the wall before the Vine leaves shade them too much. Tomatoes are very accommodating after the fruit is set; but, until then, they require plenty of light. In this house, when the Vines were younger, I had as many as forty large fruits of Trophy on a square foot, but I cannot get that now. In July, 1874, I cut eight fruits of Trophy in a bunch, which weighed 6 lb. The largest single fruit I cut of this variety weighed about 2 oz. short of 2 lb. In this house last year I did not get many fruits at the bottom, but towards the top, especially in the autumn, the produce was excellent. I grow the same

varieties here—the old Red and Trophy—as in the early house, but I am trying a few of Hathaway's Excelsior and six plants of Acme. In growing Tomatoes on the single stem system it is necessary that all the side shoots should be pinched out.

Let me now give some account of a supplementary crop which I had in my Cucumber house, a lean-to 80 ft. long with an east aspect. At the end of September, having a fine lot of plants ready, I pulled the old Cucumbers up and planted Tomatoes in the same soil 12 in. apart, training them in the form of single stems up the trellis. These plants fruited well and supplied an abundance of Tomatoes from Christmas to the middle of February, when they were pulled up to make room for Cucumbers. Had it been possible to plant the Tomatoes two or three weeks earlier, they would have done better still; as it was, I found that very few fruits set after Christmas, but doubtless more sunshine would have made a difference.

As to varieties, first on my list stands Trophy, but this requires room to run, and but little fruit is got off it till it reaches the wires. This is the finest flavoured of all I have tried; it is always admired for its fine appearance, and with those who eat the fruit raw as grown it is a great favourite. I find this kind to require starving in order to get the first blooms to set; after that more liberal treatment may be given. Secondly, the most useful sort for general cultivation is the old Red, and, with liberal treatment, this variety acquires a larger size. I weighed some of the fruit which I raised in the Cucumber house at Christmas, and found them to weigh 8 oz. and 9 oz. each, although this is a light-weighting variety. Winter fruit do not turn the scale as that grown in summer does. In regard to Trophy, I forgot to mention that after the first fruits are set, it should never be allowed to get dry or the fruits will crack, and it requires plenty of ventilation. Of Acme I had some good fruits last year at the end of June, but later on when I wanted them they failed to come, and they cracked very much. I will not, however, condemn it, as it was grown in a Vinery, and the treatment was not such as I should have given it anywhere else.

In saving seed, as soon as the fruit is ripe, take the seed out, or it will spear and be useless. I have grown Tomatoes in large pots very well; Keyes' Early Prolific and Earley's Defence are very suitable kinds for this purpose. During some years I have planted Tomatoes 3 ft. apart and trained up three stems, but in that case one must keep all the side shoots well pinched in. Acme, being so prettily coloured, is well worth growing, and it is a kind that is well flavoured.

In order to have Tomatoes in perfection, they should remain on the plant till they are ripe. This is my plan, but in clearing out the old plants any fruit that happens to be unripe should be placed in layers in baskets or boxes covered over and kept warm. Under such conditions, they soon acquire colour, and are fit for market. It is astonishing the length of time they will hang after they have become red. Being troubled with wireworm, in planting we cut a Potato into two or three pieces and place them about 4 in. from the stem. These act as traps, which can be examined every third day and the wireworms destroyed. I have found these pests to be very troublesome in new soil, but after the plants get fairly established they sustain no harm. The chief points in Tomato growing consist in having strong plants to begin with, then plenty of water, afterwards liberal feeding, and abundance of ventilation. My practice is, as soon as the fruit sets, to take out the centre piece of the leaf, an operation which assists the swelling of the fruit.

STEPHEN CASTLE.

Broadwater, Worthing.

VEGETABLES AND FRUIT GROWING FOR MARKET.

THE information which Mr. Groom gives (p. 237) respecting fruit culture in Kent is interesting; but quoting the fact that "really first-class Keswick Codlings fetched only 2s. per bushel" does not prove that fruit culture generally was unprofitable in Kent at the time of which he speaks. There are losses to be borne in every business, and I do not suppose fruit culture to be exempt from them at times. Now, if those interested will turn to Vol. VIII. of *THE GARDEN* (p. 465), they will find an instructive account of Kentish fruit culture, from which I venture to make a few extracts. At Sittingbourne is a 9-acre plot of Cherries and hard fruit, which has yielded £30 per acre, on an average, for five years. An old plantation of the same, which lies well near Barden and Tunstall, has produced an average of £34 per acre for thirteen years. A little estate of 88 acres has for fourteen years yielded fruit worth £19 9s. 6d. per acre. The lowest average quoted is £13 14s. per acre for thirteen years, other plantations having furnished a yearly average of £20, £19, £27, and £17 per acre, the bottoms for grazing being let at £2 per acre, an allowance being made to the tenant for a proportion of rates and tithes. A plantation of Green Gage Plums at Gillingham "bore abundantly one year, making, I believe, more than £100 per acre. The owner was offered £50 an acre for the fruit on the whole 28 acres (£1400), half of which was not nearly so valuable as the Green Gage part." So much for Plum culture. In the same paper as much as £100 per acre is mentioned as having been obtained in exceptional seasons by the culture of Gooseberries, Black Currants, and Kentish Cob nuts. For the very ordinary systems of fruit culture now generally adopted, however, these last returns are as exceptional, on the one hand, as Mr. Groom's illustration, to which I have alluded, is on the other. From a proprietor's point of view, fruit culture in Kent, as elsewhere, is profitable, much more so than some would have us believe, seeing that land suited for fruit culture is worth more by 50 per cent. at least than other ground in the same neighbourhood equally good, but under arable or pasture crops. There is much market garden land in Kent, and also around London, let at from £4 to £6 per acre, while close alongside such plots, similar land planted with fruit trees fetches from £10 to £15 per acre, and is considered to be better worth the money. These facts speak for themselves, and show very plainly that it would pay landed proprietors to plant good land near towns with suitable fruit trees, previous to letting it to market growers. That fruit and vegetable crops are profitable on the farm, even although they cost more producing and marketing than ordinary farm produce, is well known, and we even find Mr. Mechi growing Strawberries and Peas for market on his farm at Tiptree, and we can scarcely believe he would risk lowering his yearly balance sheet unless he thought that they would yield a good profit.

Mr. Groom tells us that London is not always the best market for fruit, and that the cost of carriage and marketing Apples from Kent is 1s. per bushel, a very moderate cost, seeing that Cherries from the same county cost 3s. per sieve for gathering and marketing. Large quantities of good fruit are wasted in fruitful seasons; hence the reason I have so often recommended that the unsaleable surplus should be preserved or canned, as is done in America and France. I took exception to "C. W. S.'s" statement, that "both for hardy and indoor fruit there is always a ready sale," because that statement certainly "fails to fairly represent the case," especially when on the very next page (p. 200) we are told that "hundreds of bushels of good Plums, Apples, and similar fruits are allowed to rot," which proves most conclusively that there is not always a ready sale for them, even "at a price" that is barely remunerative. The same market is open to both home and foreign growers, and, as I said before, home fruit growers must protect themselves. The best proof that foreign growers do, on the whole, export their fruit at a profit is that the imports generally increase, which they would not do unless a profit were made.

As to the fruit v. meat-growing question, it is admitted that more than £100 worth of fruit and vegetables can be produced on two acres of good land in three years. Now is it possible to obtain £100 annually from 6 acres of a meat-producing farm? He would be a successful man indeed who could make £2000 a year from a meat farm, or any other farm of 300 acres, unless fruit and vegetables be grown; and yet this is only about half of what the farm should yield, if it be true that large holdings give better returns than small ones, or if the results are to be equal to those derivable from fruit and vegetable culture combined, and they must be so combined if the best results are to be obtained. I am well aware that fruit crops generally are not so certain as vegetable crops or farm crops, and yet if a fair crop be produced once in three years, fruit culture is too remunerative to be abandoned. There is a fruit, vegetable, and flower farm at Fulham for which a rental of £12 per acre has long been paid, and I am told the proprietor is satisfied with a fruit crop every three

years. The market gardeners are far better off than the farmers, so far as foreign imports are concerned. The American growers cannot compete with our own in the production of fresh, soft fruits or vegetables, as they do in the farmer's case in the production of fresh meat and corn. All over the country our farmers have had from 5 to 10 per cent. of their rents remitted by their landlords during the past year, and if this has been done in the case of men paying from 40s. to 50s. per acre only, how is it that market growers of vegetables and fruit, who pay from £4 to £15 per acre can afford to do so, if it be not that this branch of land culture is more profitable than farming? Proximity to London or other large towns does not wholly account for the high rents paid by market growers, nor does the cost of planting, since in most cases this has been done at the tenant's own expense. Good land is worth more to them than to any one else, unless it be the speculative builder, and this is the principal reason that high rents are paid.

It is easy to see that the market grower's position is not so good as it was; the fact cannot be denied that cheap imports have lowered his profits, and his remedy is to grow better crops than those imported at an equal or lower cost. If manual labour is too expensive he must use horse power. The land must perforce be cultivated and increased crops must be obtained; again we must meet the foreign imports and their tendency to lower home prices by growing more fruit and vegetables, especially of such easily-damaged kinds as will not bear carriage well from abroad. The foreign grower obtains the best general price for his fruit during our times of greatest scarcity; hence we may compete best with him by extending our fruit and vegetable-producing area to its utmost limit. The only real drawback to a more extended system of fruit and vegetable culture is the distribution question. Consignments of all garden produce sent to Covent Garden and other metropolitan markets are now in comparatively few hands; indeed, it is not going too far to say that the fruit salesmen have it in their power to form a "ring" by which the wholesale prices are fixed. They have comparatively no risk, and yet they monopolise a large share of the profits of the grower, and increase the cost to the consumer as well. As I have before said, they favour the influx of foreign fruit, because the rapidity of open auction sales affords them a better chance of speculating with advantage to themselves. I have often thought that if a little of that spirit which induces fruit growers to let their produce rot on the ground rather than market it when profits are too low to be worth their notice, had been displayed by them at the first auction sales of foreign produce, they might have competed to better advantage with their opponents.

The Continental grower, however, of both fruit and vegetables makes his greatest gains by bringing his produce into the market two or three weeks earlier than our own climate will allow being done. Our own cultivators must undersell him at all other times. Large growers of fruit or vegetables can never deal directly with the consumer; they can sell their fruit by auction, or instead of sending it to London, which it appears is not always the best market, they might place agents of their own not only in London, but also in all our principal provincial towns, and then trust to the telegraph wires in order to find the best market. For the sale of the finest fruit especially, a co-operative fruit store might be tried in London with advantage, and, if carried out on a broad basis, such an institution would be sure of success, for then people would buy their fruit, as they now buy their other supplies, with far more comfort than they can possibly do in Covent Garden. F. W. B.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The Regent Potato.—This variety which has been so much eulogised by several contributors could not be mistaken for Dalmahoy. The Red Regent is the best as a thoroughly good second early sort, fit for raising the first week in August if planted in March.—E. P. LEGGE.

Dwarf Peas.—These must not be wholly condemned. No two better Peas can be grown than the Kentish Invicta for a first crop, and Hare's Dwarf Marrow, which I never found to exceed 4 ft. in height. Concerning the last named, the verdict I have always heard is "Could not be better."—EUGENE P. LEGGE, *Court House, Litton Cheney, Dorset.*

Earthing up Potatoes.—Whatever may be the necessities of Potato culture in fields that in gardens should not be performed in the same off-hand way, and no implement can well be more unfit for the purpose of earthing up Potatoes than the hoe. Misled by the instructions commonly given as to planting in rows at 2 ft. apart, &c., persons continue planting so close together that when the haulm or shaws are above ground, they are driven to the necessity of using the hoe as an earthing implement or of doing nothing. In-

stead of planting at 2 ft. apart, let the rows be according to the sort, from 2 ft. 6 in. to 3 ft.; use a fork to earth up with instead of the hoe, and far better results will be obtained. It is an excellent plan to line out the ground to be planted in widths as may be required; then in digging work down each portion, and throw it into a ridge. When this has been done throughout the entire piece to be planted, the furrows should be forked over deeply and left lying as fine and loose as possible. At planting time strain a line along the furrow, draw a shallow drill with a hoe, in order that the sets may lie regular and even; plant and dress with artificial manure, wood-ashes, soot, or other useful light compounds; then fork down the finer surface of the ridges, and cover the tubers to a depth of 4 in. When the plants are through the soil, fork over the intervening spaces, and when the haulm is from 6 in. to 8 in. in height, earth up carefully with a fork, and perform the operation again some eight or ten days later, leaving the ridges sharp and neat throughout. With such wide cultivation it is possible to plant winter Greens between the rows, and a good dressing of manure may be worked into the furrows before planting. The crop resulting from the wider space allotted will certainly repay the extra trouble.—A. D.

Lettuces Running to Seed.—The German plan (see p. 296) of preventing this cannot be called new, as it has been practised here for many years. Our mode is to cut the stem nearly three parts through, securing the Lettuce to a stake, and inclining the head to the north as much as possible. During hot weather in summer, when any deficiency is likely to happen between the different plantings, we have, by means of this method, prolonged the supply for at least a fortnight. I have known German Greens, grown for competition, to be treated in a similar manner, in order to prevent them from bolting.—DAVID MURRAY, *Cutcean, Ayrshire.*

THE INDOOR GARDEN.

HOYA CARNOSA AND BELLA.

THE best known and most useful species of this handsome genus are *H. carnosa*, a fast-growing creeper, and *H. bella*, a dwarf and more delicate growing kind. Both have thick, fleshy leaves, and both produce abundantly for a considerable period in summer, clusters of wax-like flowers, from the centre of which exudes a single drop of a honey-like fluid, which has led to their receiving the name of honey plants. Although these two species of *Hoya* are commonly classed as stove plants, and they may, indeed, be cultivated successfully in a stove, yet *H. carnosa* will grow equally well in an intermediate or warm greenhouse, and will often flower more freely in such a structure than in the stove, simply because its drier atmosphere leads to the better maturation of the wood, without which flowers must be scanty. In the stove the plant should stand in the full sunshine during the time the growth is being made. When grown in a low temperature it must not be over watered in winter; indeed, during that period this class of plants should be kept comparatively dry. If ever disease overtakes the plants it is generally caused by using too large pots, and plying the watering-pot too freely in winter, when but little root-action is taking place. Very large plants of *H. carnosa* can be grown in very small pots; indeed, I saw a large plant last year growing on the back wall of a damp stove that had absolutely no soil at all. It had originally been planted in a small chink of a border in the back path, but the branches, wherever they touched the damp surface of the wall, had thrown out roots like those which the Ivy generally and Fig sometimes do, and when I saw it the connection with the border had been a long time severed without having produced any effect upon the plant's health or progress.

Both *H. carnosa* and *H. bella* make admirable basket plants; indeed, they show to better advantage treated in that way than in any other, as their drooping flowers seem intended to be seen from beneath. *H. bella* is especially a choice subject for a basket, but its culture must be confined to the stove. It is not so hardy or robust in constitution as its vigorous relative, but it is more elegant in appearance, and in a choice collection

of stove plants it will always attract attention. Like many other of our choice-flowering hothouse plants, the taste for foliage has driven them, temporarily, into the background, but plants, in themselves so beautiful, cannot long remain in obscurity.

The main cause of failure (where failure occurs) in the culture of this class of plants is potting in soil of too close a texture. *Hoyas* are impatient of stagnant moisture about their roots, and the material forming the root medium must be of a porous character. In potting specimens of considerable size, the pots must first be well drained; more attention should be paid to this, in this case, than is customary or even necessary for the general run of stove plants. The soil should consist of about equal parts of good turfy loam and peat, pulled to pieces with the hand, and the fine, light particles should be shaken from it so that only the turf remains; to this should be added about a sixth part of sand and the same quantity of broken charcoal. In such material the plants may be firmly potted, leaving sufficient space at the top in proportion to the size of pot used, for giving water, as in the growing season the plants delight in and require a liberal supply of moisture both at the root and in the atmosphere. It is only stagnation that must be avoided. In potting small plants the turf should be broken up small, but never sifted.

The best position for *H. carnosa*, if grown in a pot, is trained on a wire trellis just under the roof, or it may be trained over a wire trainer, either globular or of any other desired shape. *H. bella* must be neatly supported with small stakes, but no more than are necessary should be used, as they add nothing to its beauty, and the roots of a plant are often injured by having the ball honeycombed with stakes. A very handsome basket of plants for suspending in the stove may be filled in the following manner: A plain wire basket of a suitable size should be procured, 10 in. in diameter and 6 in. deep, which will grow a fine specimen. The bottom and sides should be lined with Moss, and towards the top of the basket should be worked in half-a-dozen small plants of *Panicum variegatum*, with the ends of the shoots hanging through the wires, which will be pegged under the bottom, and form a beautiful covering for it. In the top of the basket should be planted five or six healthy plants of *Hoya bella*, pressing them in firmly and then covering all in neatly with Moss. After the plants are well established the basket may be hung in the full sunshine, except when the *Hoya* is in flower; then a little shade will be beneficial. Most of the *Hoyas* are readily increased by cuttings of soft, young shoots in sandy soil in a brisk bottom heat, either with or without the assistance of a bell glass. If a plant should become sickly, it is best to start afresh with a young one, and they are so easily propagated that a few young plants of *bella* might always be coming on. Plants in a bad state of health are difficult to restore, as it, in nearly all cases, arises from decay of the roots through imperfect drainage, or the soil having become close and sour. There was years ago a variety of *bella* under the name *Paxtoni*, if I remember rightly, that had a slightly more vigorous habit, but otherwise resembled it. When mounted on wire the flowers of all the species are useful for bouquet making, although if used too freely they impart to the bouquet a rather too formal an appearance.

E. HOBDAY.

Primula amoena.—I observe that Mr. Gumbleton alludes to this beautiful Japan Primrose as *Primula Sieboldi*. It would be well if this appellation were universal, but I hesitate to employ it until botanists have decided as to its proper title. I wish now to say that it is not possible to display the full beauties of this handsome *Primula* until it has been grown for a couple of years in large pots. The crowns are then thick, the foliage abundant and dense, and the flowers thrown up strongly and in abundance. Early in its growth

the foliage is crowded up into a mass, but as it lengthens in stem, it falls in a graceful way round the pot, and the numerous flower-stalks carry a very ornamental head of bloom. It is an especially beautiful species for the cool greenhouse or conservatory.—A. D.

ABUTILONS GROWN FOR TRIAL AT CHISWICK.

BY A. F. BARRON.

THE following varieties were all propagated from cuttings early in spring, and grown and flowered in pots in a cool greenhouse. For this purpose few plants can be more highly recommended, or are better adapted for the autumn decoration of the conservatory. Good plants planted out early in June will grow and flower well, and are very suitable for the sub-tropical garden.

ANNA CROZY (Bull).—Plant of robust, vigorous growth; fine habit; flowering freely late in the season; good for winter flowering. Leaves large, broad. Flowers large, and of finely cupped form; pale lilac, with dark veinings. Very pretty.

ALPHONSE KARR (Lemoine).—Plant of tall, free growth, and fine branching habit. Leaves small, deeply cut. Flowers small, of fine rounded form, borne on long slender stalks; colour reddish-orange, with dark veinings. Free flowering.

BERANGER (Van Houtte).—Plant of tall, erect habit of growth; not branching. Leaves large, deeply cut. Flowers very large and elongated, of a clear pale orange colour, beautifully streaked with dark brown. Very showy, but somewhat shy flowering.

BOULE DE NEIGE.—Plant of fine free-branching habit. Leaves of medium size, somewhat pointed. Flowers of medium size, of finely-cupped form; pure white. Very free flowering. Excellent.

COMTESSA DE MEDICI SPADA (Van Houtte).—Plant of strong, robust growth. Leaves large, woolly. Flowers of medium size; pale lilac. Very shy flowering. Worthless.

DARWINI (Lemoine) (Fraser).—Plant of free, vigorous growth. Leaves large, broad. Flowers bright orange, with darker veinings; fine-cupped form. Not free flowering.

DARWINI COMPACTUM (Lemoine).—A compact-growing, free-flowering variety. Flowers reddish-orange. Inferior.

DARWINI GRANDIFLORUM (Bull).—Plant of fine habit. Leaves large. Flowers very large, of longish form, of a pale orange colour, with dark veins. Free flowering and good.

DARWINI MAJUS (Lemoine) (Bull).—Plant of smaller growth, but in other respects very similar to D. grandiflorum.

DARWINI ROBUSTUM (Lemoine).—Plant of fine, compact habit. Free flowering. Flowers orange, shaded with rose; of fine form. Distinct and good.

DARWINI TESSELLATUM (Veitch).—Plant of fine, robust habit. Very free flowering. Flowers bright orange, similar to Darwini. Leaves large, broad; beautifully variegated or marbled; light green and yellow. A very ornamental plant, whether in or out of flower.

DUC DE MALAKOFF (Fraser).—Plant tall; free growing; not flowered.

LOUIS MARIGNAC (Bull) (Lemoine).—Plant of fine habit. Very free flowering. Flowers large, of finely-rounded cupped form; clear pale lilac colour, with slight venations. Very pretty. Distinct. One of the best. First-class certificate.

LOUIS VAN HOUTTE (Bull).—Plant of compact habit of growth. Free flowering. Flowers large, of fine cupped form, but somewhat rough; dark purple colour, with white throat. Distinct and beautiful.

MONTGOLFIER (Van Houtte).—Plant of tall, free growth. Leaves large, deeply out and pointed. Free flowering. Flowers large, much expanded, of loose form, of a dull pale yellow colour. Worthless.

MEGAPOTAMICUM (Van Houtte).—Plant of slender, spreading habit. Leaves small and pointed. Flowers small, bell-shaped, and

singularly beautiful, the calyx being dark red, the corolla pale yellow, and the stamens dark brown, in very pleasing contrast.

MEGAPOTAMICUM VARIEGATUM (Van Houtte).—A variegated leaved form of the preceding.

MEGAPOTAMICUM VENOSUM (Van Houtte).—A very tall, strong-growing variety of Megapotamicum.

NIVEUM MARMORATUM.—Plant of free growth. Leaves large, broad, downy, beautifully marbled pale green and yellow. Flowers of medium size and loose form; yellow, streaked with dark orange. Valuable as a handsome foliage plant, and very suitable for bedding.

PETITE D'OR (Bull).—Fine dwarf-growing habit. Free flowering. Flowers of fine, rounded, cupped form; of a pale Primrose colour. Very pretty. A good variety.

INSIGNE (Williams) (syn. igneum).—Plant of tall, free growth. Leaves large, heart shaped; very thick and rugose; deep green; stem covered with short brown hairs. Flowers borne on long and slender panicles; the petals short, broad, much reflexed, of a dark purplish-crimson colour, with dark venations. A late autumn or winter-flowering species. Very distinct and beautiful.

LA LORRAINE (Bull).—Very similar to Darwini grandiflorum.

LE PROGRES (Bull).—Very similar to roseum floribundum.

LE GRELOT (Bull).—Plant of fine, compact habit. Free flowering. Flowers large, and rather long; finely cupped; of a pale rose colour, with dark venation. A very beautiful variety.

LEMONNE.—Plant of fine, free habit. Leaves large, somewhat pointed and toothed. Free flowering. Flowers large; pale yellow; of finely-cupped form, borne on short stalks. A very fine variety.

LEMONNE (Van Houtte).—Same as Duc de Malakoff, of Fraser.

LILACEUM ALBUM (Bull).—Plant of vigorous growth. Flowers large, of a pale lilac colour; finely-cupped form. Very pretty, but considered inferior to Louis Marignac.

—“Horticultural Society's Journal.”

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Failure of Lily of the Valley.—Many have had their Lilies of the Valley fail this year; but the fault, I think, cannot lie with the Lily clumps or eyes, as we have had, and still have, this season some of the finest which I ever saw. Our clumps, which are obtained from two Dutch firms, have thrown up from twenty to thirty spikes each. I have always found Dutch clumps preferable to Belgian ones. The single eyes also have been fine ever since Christmas. My opinion is, that protecting the clumps before putting them in to force is the main cause of failure. I find the harder they are frozen the better they flower, and the quicker they come into blossom. I also find that placing enough dry Moss to hide the eyes loosely on the tops of the pots when they are put in to force of great service. Our conservatory now is very gay with hundreds of Spiræas, quantities of Azaleas, Rhododendrons, Imantophyllums, Amaryllises, and Orchids.—JAMES O'BRIEN, Pine-apple Nursery, Maida Vale, Edgware Road.

Thunbergias.—Any one in want of a good useful conservatory plant should sow in gentle heat a supply of Thunbergia alata and T. aurantiaca, both of which form charming edgings for masses of other plants, or for draping stages or baskets, or indeed, setting off to advantage any arrangement of decorative plants, as, in addition to their bright and cheerful flowers, their habit is drooping and graceful, and they look extremely well in suspended baskets. Such plants conceal angularities, soften down hard lines, and give arrangements strictly artificial a more natural appearance than they otherwise would have.—J. GROOM.

Conservatory Climbers.—I am about to add a conservatory to my villa at Torquay. It will be erected against the side of the house, and be between 40 ft. and 50 ft. long; the entrance hall will be reached by crossing it, so that it will be divided into two beds, surrounded by a path 4 ft. wide. Pillars and arches will rise on each side of the path, on which I desire to train a choice collection of flowering climbers. Having long been accustomed to a similar edifice, I am well acquainted with the ordinary decorations of a conservatory, but I wish to inquire of readers of THE GARDEN if any distinct plants have come under their notice that I might add to my collection. The numerous additions to our horticultural treasures may have introduced some hitherto unknown, or the constitution of some plants may have developed themselves so as to render them suitable denizens of a house of a lower temperature than a stove. I would, however, mention that to suit an invalid member of the family the conservatory in question will be kept at a higher temperature than houses of this description usually are, as the boiler is intended to heat the rooms of the villa, which must be kept at the same temperature five or six months of the year. The late Mr. Smee, in “My Garden,” mentions Stigmaphylla ciliata as thriving as well

in a conservatory as in a stove. Can any reader of THE GARDEN confirm this statement from experience? Is *Thunbergia natalensis* likely to succeed? and what Passion-flowers and Bignonias can I plant with a fair hope of success? I had for many years in a conservatory *Bignonia venusta*, the branches of which were about 40 ft. long, but it never produced a single flower. Will the different *Bougainvilleas* answer my purpose? What tropical Ferns of striking appearance can I grow at the northern end of the house, where it is intended to fix the boiler? The names of from twelve to twenty would be welcome. Has any one ever bloomed *Gelsemium sempervirens*, which old writers eulogise? I had it for some years, but discarded it from its total absence of flowers. It is now used in medicine as a sedative.—J. L.

Flowerless Stephanotis.—There can hardly be any doubt that the flowering of the *Stephanotis floribunda* is much influenced by culture, but there can be just about as little doubt that there are free-flowering and shy-flowering varieties of the same plant. It is a well-known fact that the *Stephanotis* is frequently raised from seed, and, considering how much seedlings of most plants vary in habit and floriferousness, there is nothing surprising in the fact of there being what are called "flowerless varieties" of the *Stephanotis*, and

Pelargoniums, and similar plants, furnishing as it does a soft tint of colour. We have used it for this purpose the whole winter, as well as for cut bloom, which looks well in the daytime, but not under gaslight. I would recommend all who require cut bloom in quantity to grow it, feeling sure that they will not be disappointed. Our plants of it for conservatory decoration have been grown on in a greenhouse, the temperature of which is generally about from 45° to 50° at night, with a rise of 10° by day. This variety is far in advance of any *Ageratum* previously in cultivation, both for the flower garden and for house decoration.—J. C., *Furnboro'.*

HERBACEOUS PÆONIES IN THE WILD GARDEN.

THE accompanying engraving represents one of the most beautiful effects obtained in wild gardening by an Oxfordshire gentleman, who, when he took up the subject seven or eight years ago, had before that time paid no attention to hardy plants. Struck with the idea, he partially cleared out a portion of a neglected wood, and in it and by walks and glades leading to it, planted a great variety of the more vigorous hardy plants. Herbaceous Pæonies were amongst those that succeeded best in the past early summer, when our sketch

Herbaceous Pæonies in Wild Garden in Oxfordshire.

it is mere assumption to attribute all cases of failure to flower the plant to bad culture. Nurserymen profess not only to distinguish varieties by their free-flowering habit, and *vice versa*, but also by their foliage. Not long ago I saw, in a large nursery, many plants of what was considered an exceedingly free-flowering variety. The plants were of all sizes, from a one-year-old plant up to others covering a great part of the roof of a stove, and all flowering profusely, while beside them, and growing in a tub in the same house, was a large plant of the flowerless variety, with no flowers on it at all, and which I was told was kept simply as an example of its kind. We have also had the two growing in the same house here. One flowered profusely from the beginning, yielding basketful of bloom from both the young and the old wood, while the other flowered scarcely at all, and although the latter was a large and fine plant covering a large portion of the roof of the stove, we removed it, threw it on to the rubbish-heap, and the other plant now occupies its place.—CHEF.

Ageratum Lady Jane.—This is a very accommodating and useful plant for flowering in winter. It is easily cultivated, an abundant bloomer, and its blossoms continue for a long time in perfection. We have had plants of it in flower since the end of September. It associates well with *Primulas*, *Cyclamens*, *Scarlet*

was taken; the effect which they produced was very beautiful and striking, either close at hand or seen at a considerable distance off. Herbaceous Pæonies are amongst the most free, vigorous, and hardy of perennial plants, and with them alone most novel and beautiful effects may be carried out in most places where there is room. Even in comparatively small places, a group or two outside the margin of a shrubbery would be desirable. The effect of the blooms amongst the long Grass of the wild garden is finer than any appearance which they make in borders, and when out of flower they do not seem to be in the way, as they often are thought to be when in borders and beds. It is almost needless to speak here of the great variety of beautiful forms now obtainable amongst these herbaceous Pæonies, many of which are also very agreeably scented. The older forms were not remarkable in that respect, but rather the contrary. This, it will be seen, is part of a scheme for embellishing country seats with hardy flowers without interfering with the flower garden proper at all, and without relation to the long standing dispute as regards the merits of bedding out *v.* mixed borders.

Sophora speciosa.—A Texan correspondent writes to the "Gardeners' Monthly" as follows:—"We have a broad-leaved evergreen here, called *Sophora speciosa*, that is the perfection of beauty. It is a native of this region, and grows from 10 ft. to 20 ft. high. Its flowers, which are purple, are pea-shaped, and are borne in large clusters, and very fragrant."

FRUIT CULTURE FOR MARKET.

ORCHARD FRUIT.—The end of July, and throughout the month of August, is perhaps the best time to see fruit in market gardens, but those who prefer floral beauty should visit them in April and May when laden with blossoms, and when the bright green leafage is just sufficient to tone down the too gorgeous display. A walk through Mr. Wilmot's grounds in the month of May is, indeed, a treat to any one who loves floral beauty; grand old specimen Pears, Plums, and Apples towering high overhead, intermixed with dwarfier-growing trees all loaded with bloom, are, indeed, a sight worth seeing. In the spring of 1877 there was probably the finest display of blooms ever seen near London, but, owing to the late frosts, the trees were soon left destitute of both flowers and fruit, and many growers suffered severe losses in consequence; but Pear and Apple trees, capable of bearing many bushels each, being in some gardens completely stripped. There is probably no body of men more alive to the value of the surface culture of the soil between fruit trees than market gardeners, and if we compare the crops produced in such market orchards as those of Mr. Dancer, at Sutton, with those under Grass, the immense advantage to the crops found in surface cultivation, dressing, and cropping is at once apparent. For the production of permanent orchard trees market growers give the preference to maidens, as sooner producing good fruiting trees. It is their impression that these develop into good trees sooner than two-year or three-year-old trees, because the removal from the nursery at an early age induces an earlier and better establishment in their permanent homes; also that these do not require staking and are not affected by the wind, as is the case with older trees, all of which require stakes and a larger amount of attention than it is sometimes possible to give them. Maidens, moreover, can be fashioned into any shape the grower may prefer, which is not the case with older trees. In sheltered orchards the standard is still preferred, but, where winds prevail, a dwarfier form of growth proves most advantageous. For the first few years a little careful pruning is given to the trees; but, when once established and in fruit, an occasional thinning of surplus branches is all that they receive.

Nearly all the orchard land in the neighbourhood of London is cropped with vegetables. Of what are termed Grass orchards there are but few; the land is too high rented to admit of its being thus applied. Bush fruits, Moss Roses, Wallflowers, and Lettuces form important under crops. Most of the orchard trees are of the old standard form, which are allowed to grow undisturbed, the only pruning they receive being simply the removal of dead or fruitless branches. But these tall, large-headed trees of olden times are rapidly giving way to dwarfier ones, and to those which can be trained in a convenient manner, so that little room is taken up and better fruit is obtained. As old trees die out, they are replaced by a very different form of tree from that formerly planted, and these are very differently arranged about the ground. Dwarf neatly trained trees are found to produce large crops of fine fruit in favourable seasons, and they afford greater facilities for gathering it when it is ripe than the old form of standard, and much expense and labour are thereby saved; vegetable crops, moreover, can be grown between them with far more profitable results than could be obtained under large, unwieldy-headed trees, the branches of which shade nearly every inch of ground. Should a failure in the fruit crop occur where dwarf trees exist, the loss is not so severely felt as it otherwise would be, on account of there being a good vegetable crop to fall back upon. Sometimes market gardeners cut back the branches of old and useless sorts of fruit

trees, and graft the stumps with kinds of a more valuable character. Mr. Wilmot, of Isleworth, practices this method extensively, and obtains in some instances remarkably good results, but as a rule such trees are felled and replaced by young ones. Orchard trees were at one time planted in rows, at distances varying from 10 ft. to 20 ft. apart, but in many cases these have been thinned by natural causes as well as by the felling axe, and old orchards that now exist have, as a rule, a very irregular appearance.

When market gardeners plant fruit trees to fill up blanks, they do not treat them as was formerly done, viz., plant them exactly in the same places occupied by their predecessors, to be choked and shaded by the overhanging branches of their more stately neighbours; on the contrary, they endeavour, as far as possible, to plant them several yards away from where the old roots were extracted, and by thinning out the branches of surrounding trees likely to shade them, afford the newly-planted ones a much greater chance of success than they otherwise would have. When old orchard trees have been cleared to make way for younger ones, or when entirely new orchards are formed, the trees are planted at much greater distances apart than used to be the case. Sometimes they are planted so as to form boundary lines, or afford shelter to vegetable crops, but the best arrangement which I have seen is to plant in rows from 20 yards to 30 yards asunder, and from 15 ft. to 20 ft. apart in the row, the vacancies between the trees in straight lines being filled up with Gooseberry or Currant bushes. By this arrangement, good lines of Apple, Pear, or Plum trees, with an undergrowth of bush fruits, are secured, and good breadths of land are left between the lines, which can be worked by the plough or harrow without injury to the roots of the trees, whereas, as formerly arranged, all the space left for vegetable crops had, of necessity, to be worked by the spade or fork. Another great advantage gained by this mode of planting is that of being able to gather the fruit, or perform other operations necessary to the fruit trees, without seriously injuring the vegetable crops. Such breadths of land as have just been described are admirably adapted for Radish culture or Mushroom ridges during the winter, and in summer Broccoli, Spinach, or early crops of Potatoes can be grown there to perfection. In orchards where overhanging trees exist, crops requiring light and sun cannot be grown with satisfactory results, and resort has to be made to such crops as Thyme, Sage, Rhubarb, &c. Herbs thrive tolerably well in such positions, and in the case of Rhubarb, the crop is usually gathered before the trees have made so much growth as to prove injurious to it. The branches, indeed, of the trees protect, in some measure, the crowns from cold winds and frosts, and thus promote earlier growth than would otherwise be the case.

PRUNING.—Market gardeners dislike pruning in all its forms; yet, of late, many admit that by using the knife judiciously better fruit is obtained in the case of young trees than can be got by leaving the trees unpruned. Many of them prune rather hard in order to get the trees well open in the heart at starting, so as to expose the branches to the influence of the sun and air, thus inducing fruitful spurs. When, however, this end is obtained, and the trees begin to bear fruit and rank growth is somewhat subdued, they fall back into their old system, and never prune at all, except, as before stated, merely removing decayed, unfruitful, or overcrowded branches. Suckers produced from the roots of the trees are carefully removed with as much root as can be obtained, tied in bundles, and laid in some out-of-the-way corner until a convenient time arrives for them to be planted singly in rows or disposed of to nurserymen. In the former case a well-manured and deep-dug piece of ground is selected, and, after having their roots

and stems trimmed, the stocks are placed thickly in rows, 2 ft. apart, the space between the rows being cropped with Seakale, Turnips, Cabbages, or similar crops until the stocks are fit for grafting or budding.

GRAFTING.—Nurserymen now-a-days do comparatively little grafting, budding being found a better and more expeditious method, but market gardeners adhere to the old system, and "work" the stocks some 6 in. from the ground, putting grafting clay over the incision, afterwards earthing it over with soil with a view to keeping it moist and inducing the grafts to "take" more readily than they otherwise would do. If the graft, as is sometimes the case, be put on the stocks 3 ft. or 4 ft. above the ground, with a view to make standards, they are bent down and pegged firmly to the soil and covered the same as the others. Market gardeners do not, however, often raise their own fruit trees; on the contrary, they obtain their chief supply from nurserymen, a method which they find, from experience, to be by far the most profitable, as they can, as a rule, obtain better trees, and the cost is much less than that incurred in grafting, planting, and otherwise attending to young stocks themselves; and, moreover, the ground that they would occupy is available for vegetable or other more remunerative crops.

CLEARING FRUIT TREES FROM INSECTS.—Lime is often dusted over old fruit trees to keep down caterpillars and other destructive insects, and limewash is frequently painted on the old stems after they have been thoroughly cleaned of Moss. This is done to prevent the further growth of Moss; but some gardeners consider it of little use, as the cause of Mossy fruit trees invariably arises from an imperfectly drained subsoil.

KENTISH ORCHARDS.—In these, the plan mostly adopted is to plant the trees (which are generally half standards), 22 ft. by 16½ ft., with Gooseberries or Currants between them 5½ ft. apart. The cost of the trees, bushes, and labour comes to about £20 per acre. In about three years the berries will begin to bear and to make some return. Trees grow faster and bear sooner in arable plantations than on Grass. The cultivation assists very much, and, of course, the more the land is manured the greater will be the crop.

THE APPLE.—Apples are cultivated in London market gardens to a greater extent than any other fruit, as, in consequence of the trees coming into bloom comparatively late in the spring, there is little fear of any injury being sustained by frosts, as in the case of many fruits, and thus good crops are more certain. Such kinds of trees as bear fruit of large size, and that possess a handsome appearance, are those chiefly cultivated, although some of the small kinds of dessert Apples are also grown. Fair Maid of Kent, Wellington, Stirling Castle, Blenheim Orange, Kentish Fillbasket, Yorkshire Greening, Keswick Codling, Barchard's Seedling, and New Hawthornden are amongst the favourite kinds of kitchen Apples; and for dessert, Devonshire Quarrenden, Kerry Pippin, Golden Noble, Ribston, King of the Pippins, Golden Knob, and Cox's Orange Pippin are sorts highly appreciated by fruit growers. Since our markets have been so abundantly supplied with Apples from America, English growers have been rather doubtful as to whether the increase of Apple culture would be remunerative; for, although London alone is capable of consuming all that are grown in England, even in a plentiful season, the prices obtained for them in such seasons by the growers scarcely recompenses them for the gathering. In a season of scarcity, on the other hand, foreign Apples keep the prices down so low that English growers do not get much higher prices than in a season of plenty, for the Americans are capable of sending us any

quantity, and it is only the low price which their produce would fetch in a good English Apple year that prevents them sending larger quantities. In the immediate neighbourhood of London, therefore, the culture of the Apple is by no means on the increase, for the land is high rented, and old orchards are being yearly cleared off to make room for the builder, and few care to speculate in a very large way in orchard planting. True, in old-established gardens the land is kept planted with trees, as it becomes necessary; but few new fruit gardens are made. Although Apples were at one time wholly grown in the form of standards—and, indeed, they are now to a great extent—yet dwarf pyramidal trees are mostly preferred. Tall standards, however, allow of crops being grown directly under them more conveniently than dwarfs; they are, in some gardens, planted in rows about 16 ft. apart one way, and 12 ft. the other. Dwarf trees are planted much more thickly than this, the distance between them for the past few years being only from 6 ft. to 8 ft.; afterwards, every alternate tree is removed, and what remain soon develop into good fruit-bearing trees.

The true Paradise stock is that on which nearly all dwarf Apple trees are now grafted, and the amount of fruit that is gathered from these dwarf trees is astonishing. Mr. Dancer, of Chiswick, grows large breadths of Cox's Orange Pippin in this way, and with the most satisfactory results. Stirling Castle and Hawthornden are also excellent kinds for dwarf trees, as are likewise Warner's King and Lord Suffield. Quality and quantity combined is the chief aim of good growers for market, and thousands of bushels of magnificent fruit find their way yearly to Covent Garden. Another advantage belonging to dwarf trees is that gathering, pruning, and other operations can be performed, as I have said, with comparatively little labour; and, moreover, the fruit gets so little bruised that nearly every one is sound and saleable. Sorting is seldom necessary, and if the crop from an acre of small trees be less in quantity than that from the same area planted with tall trees, it is, taking all things into consideration, probably the most remunerative. From Kent come larger consignments of Apples to the London markets than from any other of what are called the home counties, but the produce from individual Kentish orchards is probably less in quantity than that from market gardens nearer London, as in the latter vegetables are grown between the trees; therefore, the land is heavily manured and yearly trenched, operations which benefit the fruit trees. Mr. Charles Whitehead, in an interesting article on "Kentish Orchards," in the Royal Agricultural Society's journal, writes as follows in reference to this:—

"It is only recently that the occupiers of Grass orchards have discovered that fruit trees require a large and regular supply of manure, and that Grass land has more than enough to do, unassisted, to repair the waste caused by constant mowing or feeding off with animals getting their whole subsistence from it. Many Apple orchards of this description, which old men can remember as having been abundantly productive of Nonpareils, Ribston Pippins, Margils, Golden Russets, and other Apples of choice quality, rare size, and excellent flavour, have been grubbed up to make room for Hops. As the best land was invariably selected for Apple orchards, in times when Hops were not so highly esteemed, it is found that Hops always thrive remarkably well in the 'old orchard' grounds. Most of the Apples now produced on the Greensand are grown on land that is dug and hoed continuously, either upon full-sized standard or half-standard trees. The former, from too much or too little pruning, and neglect of long standing, are in an unsatisfactory state, not yielding a tithe of what might be expected. The half-standards, though not frequently met with, are comparatively young trees, having been trained in

the way they should go in more enlightened times, and their fruit is of better size and quality. The land is thickly covered with trees of various kinds, so that in midsummer it is often as difficult to force a way through some fruit plantations as through an ordinary copse, and it is a question whether the under trees, whose roots are nearer the surface, do not absorb the bulk of the manure and thus starve the Apple trees. Cultivated fruit plantations in Kent are seldom manured with farmyard or stable manure, as from its bulk it is difficult and expensive to put on land thickly covered with fruit trees.

Shoddy is largely used, at the rate of from 1 ton to 2 tons per acre, costing from 48s. to 100s. per ton, according to its per centage of ammonia. This is easily got in, and suits fruit trees well. Rags, both mixed and woollen, form a capital easily-applied manure; the quantity put on and the cost are about the same as in the case of shoddy. Fish manure, Rape dust, and the refuse from furriers' and tanners' shops are all good manures. I have tried superphosphate of lime without much apparent benefit. From kainite of potash put on fruit land at the rate of 7 cwt. per acre, it was thought that good results followed, though the effect of this manure could never be traced when applied for other crops; for Apples, like Hops, absorb an enormous quantity of potash from the soil. All manures are put on in the winter, and the land is dug afterwards with the Kentish spud used in Hop gardens (a tool having four flattened tines) as early in the winter as possible, before any bloom-buds are developed, so that the diggers may not injure them and rub them off. The plantations, or 'plats' as they are locally termed, are hoed over with plate hoes two or three times during the summer to check the weeds. In the formation of an Apple orchard intended for Grass it is found in practice to be best to plant the trees on well trenched land, and to lay it down after a few years, when the trees are well established. I have planted Apple trees of the excellent variety known as Lord Suffield on Grass land and on cultivated land at the same time, both being manured in the same way; those on the cultivated land grew away from those on Grass in a remarkable degree, and bore fruit the second year, while the others did not bear for three or four years. Apples are raised entirely from grafts. The tendency to reversion in this plant, in common with others of a fruit-bearing character, renders it impossible to depend upon plants raised from seed, or upon obtaining like from like. If the pips of the best sorts of Apples be planted, they reproduce heterogeneous varieties. When chance has developed a prodigy, it is a fact well known to fruit growers that this can only be surely perpetuated by scions or grafts.

Notwithstanding this, there can be no doubt that Apple trees produced from cross-fertilised seed would be more vigorous and fruitful than those reared in the usual way from a long series of stocks propagated by scions. Mr. Darwin shows most clearly in his recent interesting work that cross-fertilisation of plants improves them in most important points, and that continuous self-fertilisation through many generations tends to gradual degeneracy. The conclusions arrived at by Mr. Darwin, after a most elaborate exposition of experiments upon various plants, are that cross-fertilisation is generally beneficial and self-fertilisation injurious. This is shown by the difference in weight, height, constitutional vigour, and fertility of the offspring from crossed and self-fertilised flowers, and in the number of seeds produced by the parent plants. . . . After plants have been propagated by self-fertilisation for several generations, a single cross with a fresh stock restores their pristine vigour. There has been a fallacy prevalent, that trees raised from grafts do not survive the parent stock—that when an Apple tree dies, all those trees that have been propa-

gated from scions taken from it die in mournful accord. Mr. Knight, President of the Royal Horticultural Society in the latter part of the last century, firmly believed in this curiously unnatural provision, and attributed the decay of the best sorts to its action. Kentish growers now generally, however, discredit these absurdities, and attribute the decay of some old sorts, as the Ribston Pippin and the Nonpareil, in particular places to the exhaustion of essential elements in the soil, to bad treatment, to constitutional debility, and liability to blight and canker. To these causes may be added the change in the temperature, to which allusion has been made. The Crab is the proper stock upon which to graft Apples, but as the supply of these stocks is limited, the best stocks are selected from those that have been raised from pips for that purpose in a nursery, and are grafted with scions of the kind required. The stocks are chosen from those sorts which have clear, hard stems, and the trees are moved into the orchard when they are from four to five years old.

PRUNING.—Most growers cut young trees hard in the first year they are planted out, as this is supposed to favour root development. A most successful grower, however, objects to this practice, considering 'that the tree has enough to do to establish its roots without being weakened by cutting.' For the first few years the young Apple tree should be pruned so as to keep the middle well cleared out and the leading shoots as level as possible. When the tree is well established slight pruning only will be necessary once in two or three years. Very few growers prune their Apple trees scientifically or manage them thoroughly in other respects. Here and there a plantation may be found where the trees have received systematic and proper treatment from the date of planting, where good fruit is produced in abundance; and it is asserted confidently that the land in Kent really suitable for Apple growing may be made to yield fruit not much inferior in quality to the traditional Nonpareils, Scarlet Nonpareils, Golden and Ribston Pippins, and other sorts, whose sweet memories linger yet in the recollection of Apple-loving octogenarians. To ensure this, however, there must in most cases be a fresh start; the land must be unexhausted, the management more skilful, and the treatment altogether more liberal. It is better to prune Apple trees in the autumn, as soon as the fruit has been gathered, because it is more likely that fruit buds will be developed from pruning at that season than after winter cutting, which usually tends to create unproductive wood. The pruner of trees crowded with wood must aim at gradually cutting the oldest superfluous branches, so that each branch left may stand out by itself, and get a full share of air, light, and sun. If the fruit grower employ only ordinary labourers to prune his trees, he should examine each tree himself, and mark with chalk those branches which he thinks should be cut away. In the case of young trees that have been properly trained, and of older trees that have been reduced to a proper state by gradual pruning as above described, the amount of pruning required is very trifling. The fruit in most sorts comes upon spurs or short twigs on wood that is at least two years old, generally from buds that are covered till late in the autumn with clusters of dead leaves. The chief objects are to ensure a proper supply of these fruit-bearing spurs, and to keep them from being crowded and starved out by unfruitful shoots or suckers that grow out on all sides in many sorts. There are a few varieties, however, in which the fruit is grown upon slight shoots. These require thinning out and shortening if possible to prevent the fruit from receiving injury from wind.

VARIETIES.—The chief sorts grown in Kent are, commencing with dessert Apples, the Ribston Pippin—the best of dessert Apples—now, unfortunately, a somewhat shy

bearer. The King Pippin is much grown in Mid Kent and the Weald; this is a handsome Apple when well grown, but it is inclined to be specky on the rag-stone, though doing better on the Weald clay. Joanettings and Summer Pippins (early kinds) are also grown and bring good prices. Red Quarrendens, Farleigh Pippins, Pearmaines, Nonpareils, Golden Knobs, which ordinarily keep well until Apples come round again, bringing high prices in Covent Garden Market, are found in most Kentish plantations and orchards. The Margil, whose flavour is nearly equal to that of the Ribston, and, as Dr. Hogg remarks, is of a better size for dessert, is too shy a bearer, and is not, therefore, extensively grown. The Blenheim Orange, a large and handsome Apple, is much grown near Maidstone and in the Weald. Cox's Orange Pippin has been planted extensively of late. This is a high-class Apple for dessert from November to January, supposed to have been raised from a pip of a Ribston Pippin. The principal cooking Apples grown in Kent are Keswick Codlins, Gooseberry Pippins, Hawthorndens, Northern Greenings, Wellingtons, Winter Greenings (all valuable sorts), the Golden Noble, and Lord Suffield (a very fine-flavoured, early-bearing sort). Tower of Glamis and the Manks Codlin are chiefly planted now. In most old Apple orchards there are several other sorts of little value, such as the Gough, an acid and very low-class Apple, but an abundant bearer. Cider is but little made in Kent now; its quality is comparatively poor, and the natives prefer beer, and there being but little demand for cider, growers send windfalls and low-class Apples in barrels to London, where they find a sale at some price for the 'smashers,' as low-class jam makers are styled in costermonger parlance; though, as a correspondent remarks, 'since the Adulteration Act there has not been such a demand for rubbish.' As many as 500 bushels per acre have been grown in plantations where the trees were in their prime. Taking an average of seven years of the average Apple-growing land in the county, the crop per acre per annum would be about 130 bushels. The average price per bushel home to the grower for Apples for the last ten years has been about 2s. 2½d.; the expenses for picking, packing, carriage, commission, and return of sieves, amounting to 1s. 4d., having been deducted. For the preceding ten years, the average price, clear of all these expenses, was about 1s. 10d. per bushel. The annual yield per acre of the orchards under Grass must be regarded as being 20 per cent. larger than that of the plantations in respect of Apples, but the average annual yield of both taken together amounts to about the quantity of bushels stated above. The fruit growers in Kent do not appear to have tried growing, upon a large scale, Apples and Pears on low bush trees, obtained by working upon the true Paradise stock, whose influence tends to dwarf the habit of growth, and to produce fruit abundantly. These bushes can be easily pruned and root pruned if thought desirable. There are several plantations of these in the neighbourhood of London, one notably at Chiswick, belonging to Mr. Dancer, who grows large quantities of the finest fruit upon this system, which, it is thought, might be adopted successfully by the large fruit growers in Kent."

In gathering Apples, baskets holding a bushel each are placed here and there about the orchard, and the pickers gather the fruit in smaller ones, which, when full, are emptied into the large ones. At the end of the day the baskets are carted to the packing shed, where the fruit is sorted into three sections, the largest, the medium sized, and small and bruised, the latter being picked out and placed in separate baskets. The small and inferior fruit is usually sent to market at once and sold for what it will fetch, but the best, if they will keep, are not disposed of until the best prices can be obtained for them.

MELONS.—Only in a few places near London are Melons grown to any extent. They are not considered a profitable crop, inasmuch as the demand for them is uncertain. Late Melons are the most profitable, as they come into use when other fruits are comparatively scarce, and the demand is then greater, and, moreover, they keep for some time. The chief supply, however, even of these, comes from country growers. A kind named Little Heath was some time ago grown to a large extent by its raiser, Mr. Monro, of Potter's Bar. Though not held in high estimation generally, Mr. Monro grew it to perfection. The plants were planted in a good fibrous loam mixed with a little decayed manure, underneath which are bottom-heat pipes. The plants are put out when about 8½ in. high, and the first fruits are usually ripe at the end of April. The first cut fruits of this kind realised 21s. each. The same fruits in other years realised in the market 30s. each; after these two other crops were obtained from the same plants. Many of the fruits on October 1 weighed upwards of 2 lb. each, and these were grown without the least fire-heat. Three crops of the Little Heath Melon were obtained from the same house in six months, and the fourth would be ripe in a few weeks afterwards. This sort justly claims the palm for early and quick ripening, certain fruiting, and prolificness, not only as a house Melon, but much more so as a frame variety. In one house sometimes might here be seen hanging upwards of 100 beautiful fruit at one time, each weighing from 3 lb. to 7 lb.; and three days before my visit there had been cut from this house sixteen ripe fruits for market, several others being ripe, the flavour of which was excellent. When this Melon is wanted about 4 lb. weight, and of first-rate flavour, the less heat and the less soil given it the better. Mr. Bennett, of Rabley, had one year the finest houses of Melons, perhaps, ever seen, several hundreds of fruit hanging at one time. They were even in size and excellent in every way, but many of them yielded but very little profit to the grower. The sort which Mr. Bennett grows is one of his own seedlings, which has been shown on several occasions at the Royal Horticultural Society's gardens, South Kensington, and been much admired. C. W. S.

NOTES FROM KEW.

Hardy Plants.—Few spring flowers exhibit more delicate beauty than the white-flowered variety of the Large-flowered Sisyrinchium (*S. grandiflorum*), the narrow, Grassy foliage of which considerably enhances the effect of the pure white, transparent, bell-like blossoms, which are suspended from slender stalks about 9 in. high. The original plant is one of the numerous discoveries made by Douglas, who found it on low hills in Columbia growing in dry soil. In cultivation it thrives admirably in ordinary garden ground, in any position, but it seems to prefer a northern aspect. A more singular-looking plant than Bigelow's *Scoliopus* (*S. Bigelowi*) seldom comes under observation, and it specially commends itself to lovers of the curious amongst flowers. It belongs to the Trillium family, and has a pair of broad, ovate leaves, which are deep green, spotted with black, similar to those of *Orchis maculata*, and which lie on the surface of the soil. From between these leaves arise some half-dozen blossoms on slender stalks from 2 in. to 3 in. long, and 1 in. across, triangular in outline, with the three broadest divisions greenish, heavily pencilled with deep chocolate; the three other segments are hair-like and curve inwards. It inhabits the vicinity of the Tamur Pass, not far from San Francisco, whence it was recently introduced, we believe, by Mr. Ware, of Tottenham. It thrives in a peaty soil, and, like the Trilliums, evidently prefers a shady situation. Though upwards of three centuries have elapsed since the Lion's-leaf (*Leontice Leontopetalum*) was first introduced, it is rarely met with except in botanical collections, but it is, nevertheless, an interesting plant, developing, as it does, a large, Cyclamen-like, depressed stem, with divided and very glaucous foliage, and producing a stout stem 1 ft. or 1½ ft. high, terminated by a cluster of yellow flowers, ½ in. across. It apparently requires to be grown in a hand-light, in order to protect it from excessive moisture during winter, as it inhabits rather arid districts in the Levant; otherwise, it is perfectly hardy. The *Cortusa-*

PLATE CLXXVI.

A GROUP OF HARDY AZALEAS.

Drawn by Mrs. DUFFIELD.

THESE beautiful hardy shrubs appear to be, as a rule, overlooked by planters now-a-days, for they are seldom seen in modern gardens; if, however, they are carefully arranged in groups or masses, they form, when in flower, in May and June, a truly gorgeous spectacle. Although commonly known in gardens as Azaleas, they are really Rhododendrons, the only true hardy Azalea being *A. procumbens* (*Loiseleuria procumbens*); in fact, I should imagine that formerly they were commonly known as Rhododendrons, as in a catalogue of the Fulham Nursery (Whitley & Osborn), dated 1840, they are not in any way coupled with the name of Azalea.

Most of them are of North American origin, but the common species, *A. pontica* (*Rhododendron flavum*), is a native of the Levant, Asiatic Turkey, &c. The average height of *A. pontica* is said to be from 4 ft. to 6 ft., and most of the others reach from 3 ft. to 5 ft. They thrive best in a peaty soil, under treatment somewhat similar to that which suits ordinary Rhododendrons. They are propagated by layering the lower shoots during the spring or summer months, leaving them two years before removing them. The flowers figured in the plate were cut from our group of fine old specimens of these Azaleas, some of which measure over 7 ft. in height, and as much or more through. The age of these plants is difficult to ascertain. In a manuscript book of my late uncle's (Mr. William Osborn) I read as follows: "The Fulham Nursery is supposed to have been commenced by 'Gray' early in the eighteenth century. He received many American trees and shrubs from collectors and amateurs in America, and enriched his stock from the sale of Bishop Compton's trees. In 1740 he published a catalogue of his plants, which is said to have been written by Philip Miller. In the preface to Catesby's '*Hortus Europæus Americanus*,' dated 1767, it is said that 'Mr. Gray, at Fulham, has for many years made it his business to raise and cultivate the plants of America, from whence he has annually fresh supplies, in order to furnish the curious with what they want'; and that, 'through his industry and skill a greater variety of American forest trees and shrubs may be seen in his gardens than in any other place in England.'"

From this we may imagine that many of these old plants were introduced to the Nursery by Mr. Gray. It is, however, possible that they were brought here from Brompton by Messrs. Whitley, Brames, & Milne, when they took the Nursery, about the year 1810. I am informed by my foreman, Mr. Pitman, who has been here for fifty-six years, that most of them were here when he came, and that many of them were nearly as large as they are now.

The varieties are very numerous and include a number of Belgian hybrids. I may mention the following as being some of the best:—*coccinea major*, the best of the old varieties; *Cymodoce* and *Souvenir de Mortier*, rich crimson; *pontica macrantha*, bright yellow; *Reine de l'Angleterre*, buff, shaded with red; *viscosifera*, white, tinged with yellow; *Beauté de Flandre*; *grandinosa*, bright red and orange; *Grétry*, bright vermilion and orange; *Triomphe de Rozel*, bright crimson and orange; *Minerva*, pale pink with a darker shade; *Mortier*, pink and orange; *elegantissima*, rather lighter than *Mortier*; *flamboyante*, nearly crimson; *Ne Plus Ultra*, the best Belgian hybrid; *Gloria Mundi*, intense orange; *Julius Cesar*, rich crimson; *cuprea eximia nova*, very pale pink; *Mortieriana*, in the way of *Mortier*, but darker; *Cramoisie flamboyante*, fine dark orange; *Mazarelli*, salmon and orange; *electa*, *gloriosa*; *variegata*, &c.

I am not positive as to the names of the varieties figured, but believe them to be *Ne Plus Ultra* (bright red and yellow), *cuprea eximia nova* (pale pink), *pontica macrantha* (yellow), and *pontica versicolor* (pink and yellow). A number of seedlings have been raised in England at different times, but they do not appear to have the substance of these or to be so decided in colour. Their petals, too, are less reflexed and more pointed. These Azaleas are very useful as forcing plants.

ROBERT OSBORN.

Fulham.

Myosotis dissitiflora.—Mr. Groom (p. 294) must be unfortunate as regards *Myosotis dissitiflora*, for at the present time I have many in full bloom, although the ground is covered with snow 1 in. in thickness. I find they grow with us equally well from cuttings or seed, provided the season suits, but I should think the safer course would be cuttings struck in a frame in heat.—E. P. LEGGE.

Silene var. Robin Hood.—This makes one of the prettiest and most lasting of bedding plants for the spring. It is very easy to raise from seed, very hardy, and, until the *Pelargoniums* come in, very gay though neat. As to its time of flowering, if sown in the beginning of October in the open air, next April there will be a mass of bloom.—E. P. LEGGE.

leaved Crowfoot (*Ranunculus cortusifolius*) is a handsome plant from the Canary Islands. Its leaves much resemble those of some of the kinds of *Heuchera* in size and form; hence the origin of its synonym (*R. heucheræfolius*). The flower stem, which rises 1½ ft. high, bears numerous bright yellow blossoms from 2 in. to 3 in. in diameter; it is considered the finest of all the species, with the exception of the beautiful white-flowered *R. Lyalli*, which in New Zealand is very aptly called the Water Lily of the Shepherds, and which has been the desire of all hardy plant growers to possess. The Spring Adonis (*A. vernalis*) is another very showy member of the same family, growing about 1 ft. high, with finely-cut leaves and each stem terminated by a solitary, shallow, spreading blossom from 2 in. to 4 in. across, and of a bright yellow colour. It is a native of Southern Europe and Siberia.

Greenhouse Plants.—Acacias now form the leading feature in the Temperate House, the most desirable for general culture being Rice's (*A. Riceana*). This may be termed the Weeping Willow Acacia, as it is said to grow abundantly on the banks of the tributaries which flow into the Derwent in Tasmania. Its long, slender branches covered with golden blossoms hang from tall, whip-like stems in graceful profusion. *A. leprosa* is similar in habit, but the blossoms are much larger and of a primrose-yellow shade. *A. obliqua* is a neat-growing kind, which flowers abundantly in a small state; its leaves are small and oblique in outline, and the blossoms are deep orange. *A. pubescens* is a most profuse flowerer in a large state; its habit of growth is very rigid, but compact and desirable when grown in small pots. The Natal Squill (*Scilla natalensis*) is a handsome kind, with stems rising 1½ ft. high, the upper half of which is covered with pale blue blossoms ¾ in. across. Two highly ornamental Rhododendrons are especially noteworthy, viz., *Countess of Haddington*, which forms a dense bush covered with large bluish-tinted, funnel-shaped blossoms, which have been in perfection for several weeks past, and *Princess Alexandra*, a kind which much resembles *R. jasminiflorum*.

Stove Plants.—*Cochlostoma Jacobianum* is one of the grandest and most beautiful of stove plants. It is stemless, and forms a huge tuft of leaves, which are often a yard in length and 6 in. in width, from the axils of which are produced several long racemes, the stalks and bracts of which are of a purplish shade, while the flowers are 2 in. across, with the petals beautifully fringed and of a rich violet-blue colour. Though it flowers more freely during spring, it is more or less in flower during the greater part of the year. It is a member of the Spiderwort family, and is a native of Ecuador, whence it was introduced about ten years ago by M. Linden. *Hebeclinum atroburense* is a handsome Mexican Composite, much in the way of its better known congener, *H. ianthinum*; but the flower-stalks are covered with a dense, woolly substance of a deep, reddish-purple, thereby much enhancing the effect of the violet-blue clusters of blossoms. The showy kinds of *Amaryllis* or *Hippeastrum* are very conspicuous, notably *A. marginata*, a dwarf kind, bearing a large cluster of splendid blossoms, rich crimson, profusely streaked with a lighter shade. *H. vittatum* var. *solandreflorum*, a handsome variety, differs from the original in having long, tubular blossoms, which in form much resemble the flowers of *Solandra*, from which it takes its varietal name. *Arrhizoxylum formosum* is a splendid Brazilian Acanthad, with ovate, wrinkled leaves, from the axils of which the blossoms are produced on long, slender stalks; they are tubular, 1 in. across, and of a bright scarlet colour. A very useful plant for general culture is the Violet Scutellap (*Scutellaria violacea*), as it is of dwarf, compact habit, and bears dense racemes of violet and purple blossoms very freely. The variety *robusta* is, as its name implies, of a more robust growth, and on this account is even preferable to the type.

Orchids.—One of the finest of the very numerous kinds of Epidendrum is the Two-horned Orchid (*E. bicornutum*) from Trinidad. Its blossoms, which measure 2 in. across, are of firm texture, pure white with a narrow lip copiously spotted with purple, with just a dash of yellow at the base. Luddemann's *Phalenopsis* (*P. Luddemanniana*) is no less handsome than its lovely congeners, on account of the peculiar markings of its blossoms, which are 1½ in. in diameter, with the lip of a rich amethyst tint, the sepals being of the same colour, but paler and transversely marked with brownish bars. Its habit of growth and foliage strongly resemble *P. rosea*. The large-flowered *Phalenopsis* (*P. grandiflora*) is an extremely beautiful species with pure white blossoms 3 in. across, borne on long, slender, drooping stalks. It is a native of Java and Borneo. The fragrant *Pilumna* (*P. fragrans*), with large, white, golden-eyed blossoms borne from the base of the bulbs, is very attractive, in addition to its delicious odour. One of the most beautiful of Lady's-slippers is *Cypripedium niveum*, with elegantly mottled leaves, and flowers 2 in. across, pure waxy white, more or less spotted with violet. Such a charming kind as this needs only to be seen to be appreciated. It is a native of the Tambelan Islands.

W.

GARDENING FOR THE WEEK.

Stove.

The principal stock here should now be making vigorous growth. Ixoras will be forming their flower-heads, and will be much strengthened by a liberal use of manure water; these plants are much better assisted in this way than by employing the manure in a solid form incorporated with the soil, as in a liquid state it can be applied just at a time when it is most wanted.

Dipladenias should have their shoots regularly trained to the strings or wires that support them, otherwise they get into a confused mass, from which it is impossible to separate them without injury. Such as are intended ultimately to bloom on trellises should not be trained on these until the young growths show a sufficient quantity of flowers, as bending the shoots down, in all probability, will have the effect of stopping their further extension.

Bougainvilleas.—Specimens of these in pots intended for conservatory decoration, where they will necessarily be in a lower temperature than that of the stove in which growth has been made, require special treatment, in order to prepare them for this. *B. glabra* is by far the easiest managed and most useful for this kind of work. In order to bloom it well from the time when it is started into growth in winter or spring, the soil must never be allowed to approach a dry condition, such as would cause the leaves to flag, even in the least, for when that occurs the shoots generally make little further progress, in which case the quantity of flowers which they produce is very much less than where vigorous uninterrupted growth has been maintained. For a like purpose the young shoots should be kept temporarily tied up in an erect position until the full complement of bloom is visible. As soon as the bracts of the earliest have got to about three-fourths their full size, and begun to attain their colour, the plants should be moved from the stove into a cooler, but not a cold, house; a Vinery "at work," where more air is admitted than in the stove, will be found the most suitable place for them. Here the flowers will come on slowly, and will last, after getting their full size, six or eight weeks, and they will almost be as deeply coloured as those of *B. speciosa*. If, in place of being treated in the manner recommended, the plants be allowed to remain in the stove until the flowers are fully matured, and then moved into cooler quarters, it usually happens that they all fall in a very short time.

Gardenias.—Any plants that have been forced into bloom early, and that have now done flowering, should be freely cut back, well cleaned from insects, and returned to the stove. As soon as growth commences they should be moved into larger pots, or, if not required to be grown to a larger size, a portion of the old soil should be shaken out and the plants should be replaced in fresh material in the same pots which they previously occupied. The compact-growing, free-flowering *G. citrodora* is well deserving of cultivation; its beautifully-scented flowers are always acceptable, and its occupying so little room, compared with the stronger-growing *G. florida* and *G. Fortunei*, makes it more suitable for those whose accommodation is limited.

Allamandas.—Such of these as are grown on trellises in pots should not have the shoots trained until they show flower, but ought to be kept slightly supported in an erect position, as, if bent down, they keep on breaking out afresh. They will now bear continuously a stronger application of manure water than most plants; they should therefore not be stinted in this respect, as the stronger they get the greater profusion of flowers they will produce, assuming that last year's wood was thoroughly ripened.

Caladiums and Alocasias.—These will now be in active growth, and every encouragement should be given to free, vigorous development, not by an over-lengthening of the foot-stalks, but by an endeavour to impart all the strength and substance possible to the leaves, so that, if required, the plants will be able to do service for decorative purposes in a somewhat lower temperature than that of a stove later in the season. The condition to permit of this can only be secured by allowing the plants sufficient room, keeping them near the glass, and using no more shade than is necessary to prevent the foliage being discoloured.

Marantas.—Plants that were increased by division earlier in the season will now be forming root and leaf-growth freely. Encourage a stout, sturdy state of the leaves in preference to a soft, extended development, which renders the plants wholly unable to bear even for a short time a temperature lower than that of a stove.

Achimenes and Gloxinias.—The earliest started Achimenes will now have advanced considerably, and, whether grown in baskets or pots, give them all the light possible, so as to prevent the shoots being drawn up long and weak, for upon this depends their ability to bear an abundance of flowers. The latest started bulbs should, as soon as they are ready, be transferred to the pots or baskets in which

they are intended to bloom, and treated so as to make their growth slow and strong. Gloxinias now flowering may be assisted to produce a still longer succession of bloom by giving them manure water, provided the leaves are kept in a healthy, clean condition, free from insects. Large plants intended either for home decoration or exhibition should, if possible, be set on a shed near the roof and be allowed to come on slowly, treatment that holds good with these plants for whatever purpose they are intended and at whatever time of the year they are required to flower. Gloxinias are so accommodating that they may be had in bloom for eight months out of the twelve; but to have the flowers with the strength and substance requisite to enable them to stand without flagging on the plants when subjected to a lower temperature than that in which they have been grown, or to make them equally of use for employing in combinations of cut flowers, it is necessary that they be grown slowly and under such conditions as are here described, which give them a sturdy character, very different from the weak flabby growth of both foliage and flowers too often met with.

Winter-flowering Stove Plants.—The stock of these, including *Euphorbias*, *Eranthemum pulchellum*, *Sericographis*, *Gliesbreghtiana*, *Thysacanthus rutilans*, *Plumbago rosea*, *Jacaran-das*, *Begonias*, and *Aphelandras*, must have every assistance given them, so as to obtain a stout, sturdy, short-jointed condition of the plants, giving them enough pot room to insure a plentiful supply of healthy roots, for on this depends their ability to bear the full amount of flowers of which they are capable more than upon shoot development, which, if at all of a lengthened, etiolated description, is wanting in bloom-producing properties.

Poinsettias.—Moderate sized heads of these plants on stout stems are the most generally useful. A good deal depends upon the character of the house which they are to occupy when in flower; if to do duty in a large structure intermixed with larger-sized plants, they require to be grown proportionately large; and when so managed on stems from 4 ft. to 4½ ft. high, strong and vigorous, they will produce immense heads, such as are unobtainable from dwarf plants. Where wanted, some of the old stock should at once be started in heat and moisture for this purpose, and if any small stools exist, they may be headed down to within a few inches of the surface and grown on with from one to three stems each. If liberally treated through the season they will make fine decorative objects.

Amarylises.—These most beautiful and easily-grown plants seem again beginning to receive that attention which they deserve. For conservatory decoration, when in bloom, where they can receive a few degrees more warmth than an ordinary greenhouse affords, they are invaluable; their distinct habit, and the endless variety in shades of colour that have resulted from crossing the best species, particularly adapt them for associating with the usual plants in bloom in such structures through the spring, but when so used it is necessary to bear in mind, as I have already stated, that they are not placed in too cool a position, as the deciduous section when in flower are at the same time making active leaf-growth, and if kept in too low a temperature this will naturally receive a check which is fatal to the increased size and strength which the plants should yearly attain, and upon which their ability to increase through the production of offsets depends. Whilst flowering see that they do not want for moisture, as active root growth is now also going on, and as soon as they have done blooming they should be at once placed in an intermediate temperature where they will get abundance of light, and air every day when the weather is at all favourable. They succeed best in good, strong, holding loam, well rammed into the pots at the time of shifting, and, as compared with most other plants, they require to be under-potted as to size, though restriction in this respect must not be carried too far in the case of large bulbs that have a disposition to produce offsets, but which, unfortunately, many of the finest seedlings are slow in doing. Of all the plants in cultivation I know none that are more suitable for amateurs to raise from seed, or to which more interest is attached, but where crossing is attempted none but the best broad-petalled flowers with well-defined colours should be selected to breed from, and the nearer the colour at the base of the segments approaches to white, not green, the better; this latter is of importance, as it adds so much to the improved appearance of the flowers. Seedlings are generally kept in the pans in which they have been sown, or to which they have been transferred, until they have attained considerable strength, as, if potted singly before the bulbs have got some size, with a proportionate amount of roots, they would only bear pots so small that the little soil which they hold would be continually liable to get dry through the growing season, a condition which should never be allowed to occur. One of the great advantages that Amarylises present to the cultivator is the little space which they occupy whilst making their growth, and during the time they are at rest they can be set where few other plants would do at all.

Pancratiums.—These should be grown wherever choice bouquet flowers are in demand. From their comparatively large growth they require more room than *Amaryllides*, but, like these, they are easily grown; in fact, their ability to exist under such indifferent treatment is usually the cause of their being so neglected as not to flower satisfactorily; but if, as soon as the blooming is over, instead of being placed in out-of-the-way corners, half smothered with plants of taller growth, they are set where they are exposed to full light, with little or no shade, it will have the effect of keeping their leaf-growth much more within bounds than when it is made under opposite conditions, and their flowering capabilities will be proportionately increased.

Celosia pyramidalis.—This is one of the most useful decorative plants that can be grown; its elegant, erect habit affords such a contrast to the generality of other plants, that it is never in the wrong place associated with anything else. If a little seed be now sown and treated in the way in which ordinary Cockscombs are found to succeed, the plants will do well; but, for the guidance of those who have not grown it, I may add that, like its near relative, the Cockscomb, it is very subject to the attacks of red spider, which, if allowed to become established, will ruin the appearance of the plants and correspondingly curtail the development of the flowers. A free use of the syringe on the undersides of the leaves is necessary in order to keep them clean.

Orchids.

Sophranitis, Masdevallias, and Dendrobies.—Sophranitis now gone out of flower that need fresh blocks should immediately be given these before they have commenced to grow. Any of the *Masdevallias* that are making growth must now be liberally supplied with root moisture, for there are few subjects that require so much; even the plants that are flowering want to be kept much wetter than most things. *Dendrobiums* in flower, such as *D. Wardianum*, *D. crassinode*, *D. nobile*, and others, will now maintain a gay appearance, especially if the pendulous habited kinds are, as they always should be, suspended where the pseudo-bulbs can assume their natural drooping position. When grown in pots, there is a necessity for tying the bulbs more or less erect, but nothing detracts more from the collective beauty of the flowers. All that are now making growth must be treated as to moisture both in the atmosphere and at the roots in a way conducive to shoot development; at the same time, having regard for those that are in flower, it is well to let the atmosphere be a little drier during the night than would be requisite if there were no bloom to care for. Still, these being naturally moisture-loving subjects, when in a growing state the air must never be allowed to get over dry. Plants in baskets, independent of the water which they receive from the syringe, should from time to time after they commence to grow be dipped in a pail, so as to insure the whole of the material in which the roots are placed getting moistened.

Cattleya Mossiæ.—The almost innumerable forms of this showy *Cattleya* will now begin to push up their flowers, the time for the opening of which can be regulated according to the requirements of individual cases. Where many of these are grown, and it is deemed desirable to have the greater portion of them in flower at once, it will only be necessary to keep them at a medium uniform temperature, and supply water to the roots as they require it; but where it is thought preferable to have them last as great a length of time as possible, a portion of the plants, especially those that bloomed the latest last year, and that were the most backward in completing their growth, may be kept cool and dry. In this way they will bear the temperature of an ordinary warm greenhouse, viz., about 45° at night, removing them from where air is admitted. Thus treated, the flowers may be delayed until the middle or end of June without any perceptible injury being done to the plants.

Cattleya Trianae.—When this has done blooming it will at once show a disposition to make growth, which should be encouraged. This section with many growers does not maintain the robust, healthy character common to other species, in many cases, after a few years' cultivation, dying off weakly, but I have noticed that when grown in baskets or pots and suspended near the glass roof, they rarely show any decline in healthy vigour; yet it is evident that they are much weaker in constitution than the rest of the genus, and where subjected to over-heated and too moist treatment they gradually get into a weakened condition that soon ends in death.

Cattleya labiata.—This grand old autumn-blooming kind will now commence to grow, but, like the others to which it is allied, it cannot bear too much water at the roots, and it frequently happens that through well-meant attention over-much moisture is given early in the season, and which I have found most disastrous in its effects. If the soil for this and other species now in the early stages of growth be kept just a little moist it will be sufficient.

Cattleya marginata.—The small-growing forms of this plant are generally found to succeed much the best on blocks associated

with Sphagnum. They will now begin to grow, and where any additional Moss is required it should be at once provided, as if there be not sufficient of this it necessitates a too frequent application of the syringe.

Cattleya intermedia.—The different handsome summer-flowering forms of this, though the blooms are not nearly so effective individually as some others, from the delicate tints of their long-enduring flowers are well deserving of cultivation. The variety known as *C. amethystina* is amongst the best, producing, as it does, when strong, six or seven flowers from a pseudo-bulb. It blooms in different ways, sometimes from the growths as they are just about being completed, but more generally and satisfactorily from the bulbs matured late the preceding autumn. I have found the young advancing flowers very liable to get injured by the scape becoming decayed and getting into a damp, wet condition; the same often occurs with *Cattleya Skinneri*. Care should therefore be taken that no water through drip or any other cause reaches the flower-stem until it is sufficiently advanced to be out of danger. The bloom of these will now be on the move, and the time of flowering, like the previously-mentioned *C. Mossiæ*, can be regulated as required by similar treatment, but *C. Skinneri* must not be submitted to so low a temperature as the others, as it is not able to bear it.

Temperature.—This, in the various houses, including that occupied by the hottest species, must now be increased as required by the advancing season, and the time for active growth being at hand, root, as well as atmospheric moisture, must be increased, but on no account let there be any excess of the latter, especially during the night time. Its presence in too great quantity is, undoubtedly, one of the causes that has tended to destroy vast numbers of these costly plants. —T. BAINES.

Flower Garden.

Auriculas.—The named varieties belonging to the florist section are now in full bloom, and this must be preserved for as long a period as possible. The advantage of a house to show off the plants has been well proved this week; for several successive days it has been impossible to remove the lights from the frames, even for a few minutes to water the plants; it has been snowing nearly all day, and, as I write, the cutting east wind, with blinding snow, is disastrous. As regards its effects, the largest portion of our plants are in a house where they can be enjoyed more, because of the rough weather outside. Thin out all badly-marked or badly-shaped pips; also thin the flowers of all trusses that have too many pips. Small offsets potted last autumn or early this year must now be potted off, placing the plants in a frame behind a north wall; give them plenty of air, removing the lights altogether in fine weather. See that plants of Alpines in beds are attended to, the beds kept clear of weeds, and the surface soil stirred if necessary.

Carnations and Picotees.—Such weather as we are now experiencing is very trying to the newly-potted plants in the open ground, and those who can place their plants under glass have a decided advantage. Ours are in frames, where they seem to do well. Wireworm has been troublesome this year; they eat into the centre of the stem, then work upward or down to the base of the stem. The plants attacked are speedily destroyed, and the pest is seldom seen until the mischief is done. If any trace of green fly is to be seen, fumigate so as to destroy it. It has been necessary to go over our whole collection in order to pick out weeds and stir the surface of the soil in the pots.

Dahlias.—These must not be too severely exposed to the weather as yet. If the plants are in cold frames it will not answer to expose them to the frost at night with only the glass between them and the open air. Place mats over the frames at night. Remove any plants that are established into the frames, but they must not be placed in frames from a warm forcing house all at once. The plants require plenty of air, when the weather is fine removing the lights altogether. If the best results are to be obtained sufficient space must be allowed between the plants to allow of the free development of the leaves.

Gladioli.—Still continue to plant out a few of these on favourable occasions. If possible the ground should be dry, and it is desirable that it should be well pulverised by turning the surface over when it is in a dry state. Seeds may still be sown, but to ensure the flowering of the plants next year they must be sown on a hotbed. The seeds will germinate in a fortnight, after which air may be more freely admitted to them. By-and-by when the weather is fine they may be fully exposed with the lights off. Freely supply the pots with water when the seedlings are in full growth. Run the hoe through amongst the plants that have appeared above ground. The rough, dry surface is a slight protection from frost, but when the collection is but small it is easy to invert a flower pot over each plant at night, removing it in the morning.

Phloxes and, indeed, all similar herbaceous plants grown to flower in pots may now be placed in a favourable position out-of-doors. What the largest proportion of these require are generous supplies of water at the roots and rich potting material for them to work into, and do not allow the plants to be root-bound in the small pots in which they were wintered. Place sticks to the young growths, as they easily snap off at the surface of the soil.

Polyanthuses. These are now in full beauty and are very much admired. This is a free, fast-rooting plant, and, therefore, requires considerable supplies of water at the roots; the frames in which the plants are growing should face the north, but even here it is necessary to shade. Seedlings raised from seeds sown as soon as they were ripe last year should now be planted out in a bed of rich soil behind a wall or a hedge.

Pansies and other small-growing plants of that kind in frames require attention as regards keeping the leaves free from insect pests. A close atmosphere is conducive to the spread of insect pests. All such plants continue in the most healthy condition when air can be freely administered. Should the flowers be required for any particular occasion, it is best to pick all the open blooms from the plants two weeks previous to that date.—J. DOUGLAS.

Indoor Fruit Department.

Vines.—In some instances early Grapes will now be colouring, a critical stage in the case of Vines that have in previous years been cropped too heavily, or that have not had a sufficiency of water during the present season, conditions either of which tends to the production of shanked berries. If there be any apprehension on this score it will be well to apply the remedy even before the disease shows itself, and that is to water liberally with tepid water, and mulch immediately afterwards with litter or old mushroom-bed manure, in order to retain the moisture and prevent the necessity of watering again till the fruit is out, and should there be any misgivings as to the crop being too heavy it will be better to cut off a dozen bunches at once than run the risk of three times that number shanking. Good colour and finish can only be attained by free and regular ventilation. Cold currents of air must be avoided, but a gentle circulation of rarified air is now a necessity night and day. This, of course, implies firing, but that must only be done to a reasonable extent, for the bloom will be denser if the maximum temperature does not exceed 65°. The air moisture should be lessened, but not entirely withdrawn, or red spider will soon get the mastery, if, as is probable, considering the season, it has at all established itself. Pot Vines require the self-same treatment, with the addition of more frequent waterings. Late Vineries will now require a large amount of attention in the way of tying down, stopping, and regulating the shoots, and the atmosphere cannot well be too humid, or the house be shut up with too much sun-heat from the present time till the flowers open, when a more buoyant and drier atmosphere should be maintained. Do not stop the shoots according to the orthodox fashion, viz., at one joint beyond the bunch, but according to the trellis space there may be naked, all of which should be covered, but not crowded. I have known Vines that have become decrepid, and condemned wholly resuscitated by the adoption of this rational mode of treatment, viz., allowing the lateral growths to extend in every direction so long as they could be exposed to light. Any Vines yet to be planted should have early attention, for, though they thrive when planted at any season, April may be considered the best time for planting them. As to the manner of planting see THE GARDEN (p. 224).

Pines.—The continuance of sunless weather which we have experienced has had a deteriorating effect on even the most stocky Pines, for it has been necessary to employ so much firing that the foliage has become drawn and the finest "shows" are not even equal to average ones of last year; now, however, that better weather has set in, much may be done to neutralise this evil by giving air freely during the early part of the day and closing up early with abundance of moisture, and allowing the temperature to run up for an hour or two, with sun heat, to 90° or 95°. Of course, this treatment only applies to fruits that are swelling; any that are ripening should, when practicable, be put in a compartment by themselves, as these require more air and a drier atmosphere. Suckers that were potted a couple of months ago ought now to have filled their pots with roots, and should therefore be shifted into larger pots and placed in a bottom-heat of 85°. Keep them in a close, moist atmosphere till the roots have struck into the new soil, when ventilation may be allowed as before.

Strawberries.—Incessant attention as to watering is now what Strawberryers chiefly require; under no circumstances should they be allowed to flag from want of water. As a general rule, the first blossoms produce the finest fruit, and, as soon as eight or ten of these have set on each plant, all others should be picked off, and every alternate day the plants should be watered with clear manure water.

Syringe overhead on fine sunny days when closing up, and discontinue the same as soon as indications of ripeness are perceived. Should the supply of plants for indoor forcing be likely to come to an end ere the outdoor Strawberry season arrives, it will be found to be a good plan, in order to eke out the supply of fruit, to at once place over established open-air plantations ordinary cold frames; the plants thus covered, if well attended to as regards syringing, watering, and giving air, will be quite a month in advance of the ordinary supply. The varieties *La Grosse Sucrée* and *President* are both capital sorts for this kind of semi-forcing.

Figs.—Those in pots approaching maturity should receive a final dose of manure-water, and, if the pots admit of it, they should be mulched with droppings directly afterwards, as frequent waterings are now undesirable, though anything like a dry state is to be deprecated. Daily waterings now would be the forerunner of insipid fruit; therefore, the best plan is to water at long intervals and mulch in order to retain the moisture communicated as long as possible. Give air freely, but avoid aridity and cold draughts. Trees that are planted out in inside borders with limited root run cannot have too generous treatment; always water with tepid guano-water, and syringe overhead twice daily. Pinch out the points of the side shoots at every second or third joint, and the terminal shoots should also be stopped if likely to overshadow other shoots or fruit. Figs are as susceptible as most other fruits to injury from over-cropping, and any extra fruit taken as a first crop will tell against the second; it will be well, therefore, to be content with a moderate first supply, and remove the redundant fruit forthwith.

Peaches and Nectarines.—Early Beatrice and Early Louise, the two best early kinds of Mr. Rivers' seedlings, are now swelling rapidly, and though neither of them can in all respects be placed in the first rank, they are most valuable for early "work," and a tree of each should have a place in all moderate-sized Peach houses. We have gathered ripe fruit of Early Louise five weeks in advance of that of Royal George in the same house, a fact which will show how valuable these early kinds are. Well ply the syringe and husband sunheat by closing up early, and above all, see that inside borders have no lack of water, and are kept covered with stable litter, which helps to keep up the desirable humidity. Partially disbud late houses as soon as the fruit is set, and finally disbud when the fruit has attained the size of large Peas, removing all surplus fruit at the same time. The points of the side shoots should be stopped at the first leaf, and the main terminal ones trained to furnish the trellis, which should, however, not be crowded with useless wood. The latter will not only have to be cut out at the winter pruning, but it will also prevent the ripening of the next season's fruit-bearing shoots. Young, vigorous-growing trees should receive clear water only, but abundance of it should be given, and any strong-growing shoots may be repressed by occasionally pinching out their points, or bending them downwards, in order to check the current of sap. Shoots of medium strength—small rather than large—ripen the best, and, as a matter of course, are most fruitful. As soon as green or black fly is observed, in however small numbers, fumigate with Tobacco paper for two or three nights successively, care being taken to have both the foliage and the atmosphere dry before performing the operation.

Melons.—Early fruits will by this time require support, and we have yet found nothing better for this purpose than a piece of ordinary fish netting tied at four points to the trellis with string; when thus tied, a piece 6 in. square will support the largest fruit. If water be requisite it should be given copiously now, for by-and-by, when the fruit is fully grown, it will be dangerous thus to apply it for fear of causing the fruit to crack. Keep up a good supply of atmospheric moisture as a preventive of spider, and if it should appear, sponge at once the foliage with soapy water. In compartments where the plants are flowering, take pains to fertilise them, and if about four on each plant can be operated on at the same time, they will be more likely to swell equally. The air moisture should lean to the dry side till a full crop has set, when an increase may take place; air may then be given freely in the early part of the day, and growth encouraged through forcing by means of sun-heat in the after part. If the beds for succession plants are not ready, pot on the plants, as the roots should never be allowed to feel the sides of the pots, such a check causing them to fruit prematurely and before the plants are strong enough to perfect a crop.—W. W.

Kitchen Garden.

Beds or plots of Asparagus should now have a dressing of soot, salt, or wood-ashes, which will both fertilise the soil and keep off slugs from the young shoots now emerging from the soil. New plots may now be planted in rows 3 ft. apart and 2 ft. plant from plant in the row. The old system of forming beds and covering them up annually with fresh soil should be allowed to become obsolete. If grown on the flat system and in regular lines, and the soil be kept

stirred during the growing season, and surface dressed in winter, with either a little fresh soil, rotten manure, salt, or burnt ashes from the refuse heap, the best of Asparagus will be the result. Judging from plantations in the neighbourhood of Paris, plenty of space between the rows seems to be the aim of French growers, and apparently the reason why they excel us in the culture of this esculent. Seeds of it may also be sown for transplantation next year. Seakale, Rhubarb, and Horseradish that have yet to be planted can not longer be delayed if they are to be satisfactory in growth and produce; and the same remark applies to Potatoes, all of which ought now to be in the ground; earth up early border kinds, and keep litter or Bracken at hand for covering when frost seems imminent. Thin out, earth up, and stake advancing crops of Peas. Notwithstanding the severe winter, birds are still sufficiently numerous to seriously injure these by eating out the points; therefore, we have still to use the gun in self defence. Thin out Parsnips to 8 in. apart as soon as the seedlings can be handled; stir the soil between the rows when dry, and also between all other growing crops, such as Parsley, Cabbage, Lettuce, and winter Onions. A general sowing of Kales, Broccoli, and Savoys may now be made; also a last sowing of Autumn Giant Cauliflower. The usual routine work will now consist of making frequent and regular sowings of summer vegetables and salads, such as Lettuces, small Salads, Radishes, Spinach, Turnips, Peas, and French Beans. Keep walks, alleys, and edgings neat and trim, and the ground between all crops well stirred both for the destruction of weeds and for the advancement of growth.—V. W.

AMERICAN NOTES.

Big Trees.—Prof. Brewer corrects the common error as to the height and age of the big trees of California and Australia. Although the Eucalyptus of Australia measured more in height, the Sequoias of California, taken as a whole, are larger in size. The State Geological Survey carefully measured the trees in the different groves, including several hundred in all, and found only four that were over 300 ft., the tallest being 325 ft. Only a small portion of the whole exceeded 230 ft. As to the age of these trees, Prof. Brewer says that only one was accurately counted to the centre, and that this was only a few hundred years old. He admits, however, that some may be 2000. The estimate that the age of the oldest extended back to the time of King David and the Trojan war was made by counting the thin outer annual layers of old hollow trees, and erroneously supposing the interior ones to be as thin during the young and vigorous period of the growth of the tree.

Carnivorous Plants.—Some discussion has recently taken place as to the influence on growth of the insects caught by carnivorous plants. Mr. Peter Henderson, as reported some months ago, tried the experiment on a hundred plants of *Venus' Fly Trap*. There was no difference whatever in the growth of those which had free access to insects and those from which they were entirely excluded. The experiment had been previously tried under Darwin's direction where a number of *Drosera rotundifolia* were fed with meat and made an increased growth. This result is not at all surprising when it is remembered that putrid meat is one of the most powerful animal fertilisers, and it seems surprising that the fact should have been overlooked that a highly-manured plant will always grow more rapidly than one without it. We have known some instances where special fertilisers applied directly to the leaves of plants had produced similar results. The insects caught by the plants alluded to seem not to have possessed much value as manure.—“Country Gentleman.”

Ice Storing.—It does not matter in the least whether Mr. Williams' column of straw up the centre of his ice-heap be thick or thin. It is unnecessary and wrong in principle, for the reasons I have given, and which he does not now venture to dispute. It is told us, as 230 ft. of ice, when the salt water frozen on the top almost immediately congealed, he meant during frosty weather. Are we to understand from this that he does not consider the ice-heap in an ice-house to be at or below the freezing point under the surface as long as it lasts? A bottle of water buried in the ice in midsummer freezes quicker than the same it would do in winter; and it follows, therefore, that drainage from the top, if any, would freeze in passing through the heap. If this were not so—if the ice in the body of the stack were not in a freezing state, it must be thawing—there can be no medium state, and it follows, of course, that every fragment of ice, of which the heap is composed is surrounded by a temperature above 32°; and if this were the case, why the heap, instead of lasting one or two years, would not last above one or two weeks, but would perish immediately. Did your correspondent never see an ice-piling frozen in a bucket of ice in July? Mr. Williams asks: “Where is the heat to come from in a vault wholly underground” to render his central column of straw “a channel for heat?” A query which carries its own refutation. If there be no heat to penetrate the straw communication in connection with the air at the top to the ground of the bottom, where can the heat come from when there is no straw shaft at all? and if there be no heat, how can the ice melt internally? and if it does not melt, what is the use of the central drain?—C. [Heie we discuss it should stop.]

A COUNTRY VICARAGE GARDEN.

MANY an exquisite bit of tree or shrub scenery may often be found in gardens attached to country vicarages. Away from the busy hum of towns, miles perhaps from a railway station, one often meets with gardens abounding in nooks and corners, full of the choicest kinds of hardy plants, shrubs, and trees, with just enough glass to prove the truth of Cowper's lines, “Who loves a garden loves a greenhouse too,” and just enough bedding out to show that it is possible to graft the new on the old—to introduce modern ideas without discarding all one's old-cherished favourites. Wonderfully interesting are some of these old-manse gardens; but the dignitaries of the Church in all ages have always been staunch supporters of gardening in its truest and best form. Just such an ideal place I found the other day in the rectory garden at Warboys, Hunts, the residence of Canon Hill. Many years ago, the place must have been planted and laid out by someone possessing the eye and feeling of an artist. A small stream had been coaxed from the fields near, and widened out into a miniature lake, with its island and serpentine banks so clothed and garnished with tree and shrub growth as to throw some parts into deep shadow, which seemed to enhance the brilliancy of the open stretches, and at the same time left a pleasing doubt in the mind as to its real extent. The place altogether did not consist of more than 3 acres, but the trees and shrubs were so happily grouped and blended, the grassy glades, and the open stretches of sparkling, glimmering water seemed dropping into the view just where the eye sought some relief, producing a complete and most charming picture. Another feature was an old-fashioned terraced garden on gravel, with narrow, box-lined beds, the whole surrounded by a dwarf wall, on the reverse side of which was trained new varieties of Roses, and at its base was a long border for herbaceous plants, with groups of Lilies, Roses, and other interesting hardy plants that are not near so common now as they deserve to be. A neat little span-roofed forcing house has just been built on the site of an old-fashioned lean-to pit, the glazing being done without a particle of that greatest of all nuisances in hothouse building, putty; and the future cost of painting, which in glass structures of the ordinary type is usually so heavy an item, will be thereby much reduced. I have often noticed how the leading garden in the district gives a tone to the gardens of less extent and degree around it. When visiting Belvoir some years ago, long before I reached the castle gardens, I could see their beneficial influence in the glowing masses of spring flowers in the cottage and other gardens in the neighbourhood. So it was here at Warboys on a lesser scale. The shrubs and trees of the rectory garden seemed to have overflowed in more than one direction, and I noted, during my short visit, several examples where more than average taste had been employed in their arrangement. But little illustration is needed to show that example is better than precept.—E. H., in “Field.”

GARDENERS' FRIENDS.

DEVIL'S COACH-HORSE, OR FETID ROVE BEETLE.

(OCYPTUS OLEUS.)

THIS very common and well-known beetle is not generally considered by gardeners to be an insect in any way likely to be of any service to them, and they more frequently imagine that it is destructive to vegetation; in this, however, they are very much mistaken, as these beetles feed entirely on animal food, and the number of small insects which are destroyed by them is very considerable. On no account should any of these beetles or any members of the same family be purposely destroyed, as none of them are injurious to plants. The devil's coach-horse may often be found under stones or boards which have laid some time on the ground without being moved, or running across garden paths. When disturbed, or at the approach of any danger, they turn up the ends of their bodies over their backs, and, opening their large jaws, put themselves in a very ferocious attitude, as if prepared to do battle with any comer; they look as if they would bite any one who touched them, but they are perfectly harmless, and may be handled with impunity. They belong to the family of beetles called Staphylinidae, a family which in this country is considerably larger than any other with which we are acquainted, and which contains more than 750 British species.

TREES, SHRUBS, AND WOODLANDS.

BARK AND BARK STRIPPING.

THE period of bark stripping and harvesting is one of the most anxious seasons of the year with the forester, as the quality of the bark is so largely dependent upon the weather during the time which intervenes between the stripping and the delivery, as well as upon the carrying out of the work at the proper time, to secure easy and expeditious peeling. In most cases, the time when the bud is just expanding into the leaf is that which gives the greatest weight of bark of the best quality, and with the smallest amount of labour. By deferring the work even for a few days there is often a loss in weight, amounting to as much as 10 per cent., and a great deterioration in quality.

Even in the most favoured situations it is but seldom that the season for stripping extends beyond from twenty-five to twenty-eight days. In this district (Kent) it often reaches from about the 20th of April to the 20th of May in an early spring, and from about the 1st day of May to the end of the month in a late one. Much depends upon latitude and the exposure of the situation, and farther north it is often from about the middle of May to the middle of June. The healthiest trees in the most sheltered situations break out earliest, and generally strip easily and yield good bark, while those of unkindly growth or in exposed situations linger in the bud, strip with difficulty, and yield bark deficient in tannin. Wherever hammering has to be resorted to, the cured bark is generally deficient in that bright inside creamy colour which denotes abundance of tannin matter. Such bark is also much more liable to deteriorate upon the drying stage during a wet season.

Trees growing in sheltered hollows having a southern aspect yield the best bark. Under twenty years old the trees have not arrived at perfection for stripping, and after thirty years the yield both of tannin matter and extractive diminishes. The astringent property upon which the value of bark so much depends is most abundant in trees of middle age.

A calculation of the quantity of bark to be stripped may be made from the following data: A flourishing, well-proportioned, and full-grown tree will produce from 5 to 6 cwt. of bark for every ton of measurable timber it contains. Trees of medium age, averaging 10 ft. each, will produce a ton of well-cured bark for every 150 ft. of timber; hedgerow trees in favourable situations about a ton of bark to 3 tons of timber. The yield from plantations or coppice Oak will be proportionate to the space afforded to the growing timber. Where this is ample we may estimate a ton of bark for every 4 or $4\frac{1}{2}$ tons of timber. Small Oak poles will not average more than 1 ton of bark from 5 tons. All branches of 1 in. in diameter should be peeled, as these contain in proportion more tanning matter than the trunk bark.

The number of hands required to strip and stack a given quantity of bark in a stated time will depend upon the size of the timber, as well as other circumstances. As a general rule, the larger the trees the fewer the hands. Taking the average of several years, I have found that about six or seven men, with two strong boys, will fell the trees and strip and stack 1 ton of bark in the day. The price paid per ton has for some years been £1 12s.

Before felling a tree, care should be taken to ascertain if both the body bark and that of the branches will run easily. An experienced eye will generally tell this at a glance. The necessary tools for felling and cutting up are the heavy and light axes and the handbill. For peeling the peeling-iron and the wooden mallet, made of Ash, about 4 in. square at the head and 7 in. long, with a wooden handle. This will sometimes be found necessary for loosening refractory bark, but the less it is used the better the quality of the bark.

Various methods of stacking bark are adopted in different places. One of the most common consists in placing it upon a raised stage formed of strong forked sticks driven firmly into the ground, and upon which are placed longitudinally other peeled rods, so as to form a secure platform; upon this is placed the smaller shreds of bark, the whole being securely thatched or covered in with lengths of the body bark, averaging from 3 ft. to 3 ft. 6 in. If the bark be well stacked, no turning will be necessary in an average season, when it is fit for delivery in about a fortnight; but should a long spell of wet weather follow, choose a fine day and open and re-arrange the stack. When the bark will snap between the fingers or under pressure and not bend, it may be considered fit for delivery.

During the process of curing, the inner side of the bark should never be exposed to the sun or rain. The stage should be raised sufficiently high to admit a free current of air under the bark; about 2 ft. will be sufficient for this purpose. Bark generally loses about one-third of its weight in drying if properly harvested. A dull inside colour indicates bad curing or the presence of but little tanning matter; this matter, which gives its value to bark, is found

The Staphylinidæ vary very much in size; a few species are somewhat larger than that which forms the subject of this paper, and some are hardly one-tenth of an inch long. They nearly all closely resemble one another in form, being very long and narrow, with shortish legs and very short wing-cases. They are generally black or very dark brown; some, however, are more gaily coloured. Most of them fly well, and all can run very fast. They feed entirely on animal or decayed vegetable matter. The devil's coach-horse leaves the chrysalis case towards the end of May. The female lays her eggs, which are oval in shape and unusually large (in fact they are larger than those of any other English insect), measuring about one-tenth of an inch in length, in the course of the summer. The grubs or other larvæ, for they cannot be called grubs like the larvæ of most beetles, very much resemble the parent insects, except that they have no wings or wing-cases, and are brownish-grey in colour. They run with great activity, and are very bold and voracious; they will even attack and devour their own species, and, like the perfect insects, live entirely on animal food; they may often be found under stones, clods of earth, boards, or anything, in fact, which will afford them shelter. According to Dr. Heer, they often construct cells in the earth, about 1 ft. deep, in which they take up their abode, seizing any unfortunate insect which may happen to fall into or cross it. The larva remains as such during the winter and early spring, and in May assumes the pupa or chrysalis state, which change it undergoes beneath the surface of the earth; about a fortnight afterwards it leaves the chrysalis-case as a perfect insect. It is now entirely black in colour, and rather more than 1 in. in length; the head is roundish and rather wider than the thorax, the jaws are long and powerful, the antennæ consist of eleven

ROVE BEETLE.

joints, which, with the exception of the basal ones, which are rather longer, are much of the same size; the thorax is rounded and narrower than either the head or wing-cases; the latter are very short, and cover a pair of long, well-formed wings, which, when not in use, are carefully folded beneath them; the insect uses the end of its body, which it turns over its back to assist in the operation of folding up its wings. The body is somewhat flattened; the six last joints are not covered by the wing-cases, and are hard, scaly, and well-defined. The extreme end of the body is furnished with two small organs, from which the insect can emit a most unpleasant smell, and which it doubtless employs as a means of defence. Several nearly allied species have the same means of defence. The larvæ are somewhat smaller than the perfect insect, measuring about 1 in. in length; their antennæ are very short; the first three joints of the body are the only ones which bear legs; these joints, with the fourth, are hard and horny; the remaining nine joints are soft, rounded, and fringed with hairs at the sides; the end of the body is furnished with two long, feeler-like organs; the last joint is merely a conical tube, which is used as a seventh leg. The pupa or chrysalis is not a hard case like that of a butterfly, but the insect is enclosed in a skin, through which the immature limbs can be seen folded over and the head bent upon the breast.

S. G. S.

Shaw's Patent Mineral Solution Tiffany.—A customer of ours has written as follows respecting this tiffany: "The poisonous nature of the solution which lies about the plants in the shape of powder has burnt the leaves of 700 plants, and has injured my Grapes, so that we have been obliged to remove it from the house as useless in its present state. The plants were in splendid condition before erecting the tiffany. Where a small portion of the house had no tiffany over the plants they are all right, thus clearly proving that the fault rests with the tiffany. Should not this kind of tiffany be used outside the glass and not inside? We have advised our correspondent to remove the tiffany to the outside, and give the plants a syringing with tepid water in order to remove the poisonous nature of the solution. What is the experience of your readers with reference to this tiffany?—LAMOTHEUX & Co., Plymouth.

mainly in the white cortical layers, which are situated next the alburnum or sapwood of a tree.

In felling trees of an age to leave reproductive stools, great care should be taken not to strip off the bark down to the roots, as is often carelessly done, as this destroys the continuity of the dormant buds. While smaller poles may be advantageously cut down with the axe, all trees having a diameter above 6 in. to 8 in. are better felled by the aid of the cross-cut saw; this will be found to be economy both of time and timber.

In delivering bark, it is customary to tie it up in bundles with withes for the convenience of loading. Formerly it was chopped in small pieces and afterwards delivered in bags. The cost of tying up is about 1s. 6d per ton. Chopping costs 6s. or 7s. per ton.

As soon as the stripping and stacking are finished, no time should be lost in cutting up the cord-wood and faggots, and getting the whole of the produce removed from the fall. As the speedy curing of the bark depends so much upon the airiness of the situation in which it is staged, it is scarcely necessary to remark that, for this purpose, an open spot should be chosen, well removed from the shade and drip of trees, and where both sun and wind have free access.

A. J. BURROWS.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

The Red Maple (*Acer rubrum*).—Why is not this beautiful deciduous tree more extensively planted? For some time past specimens in the Kew arboretum have been most conspicuous on account of their innumerable clusters of small red flowers. As an ornamental tree at all seasons few equal this in beauty; in spring its flowers render it especially striking, in summer its compact growth and fine foliage make it a very effective shade tree, whilst in autumn the brilliant golden-yellow of its decaying leaves attracts the attention of even the most casual observer. It is not such a rapid grower as the Silver-leaf Maple (*Acer dasycarpum*), but is neater in habit and much more handsome during early spring; its blossoms being deeper in colour by a shade or two and lasting for a longer time.—G.

Cassandra calyculata.—This pretty little undershrub is now (and has been for some time) in blossom. It forms a dense bush about 18 in. high, has small, leathery, box-like leaves, and produces its pleasing, urn-shaped white blossoms in great abundance from the axils of leaf-like bracts at the tips of the branches. It succeeds well in moist, peaty soil, is perfectly hardy, and is a native of the northern parts of Asia and North America.—G.

Lonicera Standishi.—The creamy-white, deliciously-fragrant blossoms of this Chinese Honeysuckle, and its flowering so early, render it a decided acquisition to any garden. Although not strictly a climbing kind, it makes an acceptable wall plant, and it is well worth while to accord it such shelter, as the flowers are produced under those conditions much more freely than from plants in the open border. It is a deciduous, twiggly shrub, with pale yellow-brown branches, the blossoms being developed much in advance of the leaves. To Mr. Fortune is due the credit of its introduction to this country; he found it generally cultivated at Shanghai, and sent plants from thence to the Royal Horticultural Society, by whom it was distributed along with *L. fragrantissima*, from which, however, it is quite distinct.—G.

Transplanting Trees in Winter.—It is unquestionably better to transplant trees when small from the nursery rows either in spring or autumn, but it is sometimes desirable to move large ornamental or fruit trees from the forest or pasture, or from their place in the orchard or lawn where they have been planted too close. This is best done in the winter, and by the frozen-bank method. Dig a trench around the tree, making the ball of earth 6 ft. or more in diameter, according to the size of the tree. For a tree 6 in. or 8 in. through at the butt the trench need not be more than 2 ft. deep, and may be dug at any time late in the autumn, or during a thaw in winter. The places to receive the trees are to be prepared beforehand, and furnished with rich loam. When the ground is frozen 12 in. or 18 in. the block of earth can be prised out with levers, put upon a truck, and removed to its new home. A rock-lifter or stump-puller is a much more convenient machine to do the lifting and transplanting. If the work be carefully done there is no risk at all in the removal; the roots are not exposed, and frequently the tree, the next year after transplanting, will make the average growth of wood. This method is particularly desirable in removing evergreens that have been too closely planted and begin to crowd one another. Valuable trees, six or eight years old, may thus be saved that must otherwise be sacrificed. We have frequently moved large seedling Pears from old pastures by this means, put on new tops, and in three or four years had them loaded with the finest varieties of fruit. In preparing borders for the transplanting of large fruit trees

they should be made extra large, and should be well supplied with rich compost and a barrel or more of bones to each tree.—“American Agriculturist.”

THE FRUIT GARDEN.

NEW PLAN OF FILLING A HOUSE WITH VINES.

I CALL the plan which I am about to recommend “new,” because, so far as I am aware, it has not been recommended before in any work upon the Vine nor practiced. As is well known, the usual way with young Vines is to train up one or more rods to the top of the rafter, if they will grow that length, and to cut them down again to the bottom wire at pruning time, and, during the next few years to leave a few feet of wood every season till the Vinery is completely furnished with bearing rods—a practice which requires from five to six years, according to the size of the Vinery. The plan which I propose, however, and which, I hope your readers will try and record the result, is to grow good strong canes to the top of the rafters the first year and not to cut them down at all, but leave them entire. They need not be cropped at all, or, at least heavily, the first season after planting, but they will assuredly carry a good crop the next, and should afterwards go on bearing in the usual way, thus giving the grower several years’ advantage in starting over the old plan of gradual extension. I am inclined to think this plan will succeed, from my experience with some supernumerary Vines here, which were left their full length the first season and cropped the second. These Vines, owing to circumstances which need not be specified, have, most of them, been left, and have been fruited every year since 1871, and they have always carried good crops of late Grapes, and have never produced a shanked or badly furnished bunch. Some of them have had another limb led from the base, but otherwise they have hardly extended more than 1 ft. from the points of the original rods. Some are just the same length and size as they were the season in which they were planted.

On another occasion, in 1867, I ran a Muscat Vine from an eye up to the top of the rafter the same year, about 19 ft. long, and left it that length, pruning all the others down the usual way. The year following (the second year) it bore fourteen bunches and the others two and three apiece, all about 2 lb. each; but the third year the Vine that had not been cut down, and which had been so heavily handicapped in the matter of cropping did not show a single bunch. The fourth year it did not show so abundantly as the others, but it produced enough for a fair crop, and since then it has gone on bearing like the others, from which it cannot now be distinguished, except that it has not a break along its whole length. I may state that I had no difficulty in getting every bud right down to the soil to break freely the first year of fruiting, notwithstanding the length of the cane, which was well ripened and as thick as a walking-stick.

I may state that I purpose extending a Vine of Barbarossa this year along the top of our late Vinery to the length of 60 ft., if it will grow as much as I expect it to do, and leaving it unpruned at the end of the year as a further experiment. J. SIMPSON.

Wortley.

GOLDEN CHAMPION GRAPE NEAR BRISTOL.

EXAMPLES of Vines flourishing with their roots in a cold border and their tops in a hothouse must surely be few and ill to find when your correspondents have to take us to the mild climate of the Bristol Channel to show us a Vinery in which the Vines are only pushing, and not in flower, near the end of March. I am informed that the Myrtle is hardy near Bristol, and that Fuchsias and scarlet Pelargoniums frequently stand the winter with little or no protection. Grapes, therefore, on hardy stocks, and with their roots partly inside and partly out, pushing late in March, can surely be nothing to wonder at. Here, in Yorkshire, and well up on the backbone of England, I could, at the present moment (April 5), show magnificent shoots and bunches, not in flower, on Vines with their roots entirely outside, with not a scrap of any kind of protecting material upon the border, and the treatment and the Vines have been the same for the past fifteen years. I should not be surprised if the temperature of the border was below the mean temperature of the Vinery, which we like it to be as nearly as practicable; the heat of the soil will, however, rise soon enough, and we are in no hurry with the crop, which comes on almost of its own accord. Probably Mr. Baines visited Bristol as near the end of March as the middle of it—at the date of the show there (March 20) possibly—and, if so, one feels still less surprise at the growth of the Vines at Henbury Hill. Grapes likely to be ripe in time for the autumn shows in the favoured west

of England ought to be produced without the aid of heated or protected borders of any kind, if they can be produced at all. As much is accomplished in the far north. Had the Vinery in question been full of ripe bunches instead of bunches in bud only, it would have been worth alluding to under the circumstances; as it is, it proves nothing more than one would have expected as a matter of course.

J. S. W.

GRAPE CULTURE IN MARKET GARDENS.

MANY of the practices described by "C. W. S." (p. 264) as being adopted by London market gardeners are worthy of imitation in private gardens. I am of opinion that the London market gardeners are not surpassed, in a general way, either in this country or on the Continent, judging by the number and quality of the crops which they take off their ground during the season; but in the matter of Grape culture, your correspondent will perhaps excuse my saying that I think he has been led into an error in stating that "it is remarkable how much more quickly market gardeners fill their houses with Vines than private growers." To fill the houses with canes in two years and take excellent crops off the Vines the third season, as the market gardeners are said to do, is not a remarkable feat. Many private growers who understand Vine culture ordinarily will fill their Vineries with good canes the first season from eyes, and take a heavy crop off the Vines the year following; and this goes on by a system, more than once described in THE GARDEN, till the permanent Vines come into full bearing. I have done this frequently myself, and on one occasion we finished an excellent crop of Black Hamburgs in May, planted the house the same month with newly-struck Vines, and took a crop the whole length of every rather 18 ft. long the season following, not losing a season. Between the supernumerary fruiting Vines permanent ones were run up the same season, and between the two sets a full crop has been obtained every year since, and that was in 1871. The early Hamburgs were done away with to extend the late supply. But even this quick work has been exceeded in private gardens, where Vines struck from eyes in spring were made to produce a crop of fine fruit the same season; that is, in about nine or ten months after the eyes were put in, a feat not likely to be surpassed, I imagine; but it may be performed by any one who can grow pot Vines fairly well. I question also very much if anything is gained by the practice of allowing the laterals to extend as much as five and six joints beyond the fruit, which the market gardeners, according to "C. W. S.," consider enables them to crop their Vines "much heavier than they otherwise could do." It is important to have sufficient good and mature foliage upon the Vine; but whether it be before or behind the bunches does not matter in the slightest degree. Indeed, considering how closely together market gardeners grow their Vines, as a rule, I am puzzled to understand where they can find room for such a profusion of lateral growth. I doubt if either market or private growers exceed or approach the Grape growers at Thomery, near Paris, in a general way, as regards constant and heavy crops; and yet their system of training and pinching the shoots is the most severe that could be devised. The Vines are planted only 1 ft. 4 in. asunder; two shoots are often trained from one bud; many of the shoots carry two bunches, and all are pinched just about one leaf beyond the last bunch, and no after growth is permitted, for the laterals are pinched as soon as they can be laid hold of by the finger and thumb. The leaves are also thinned out when the fruit begins to colour early in August, to let the sunshine reach the bunches. Yet the Grapes so produced are well finished, crisp, and excellent in flavour. It would appear that a certain quantity of foliage is needed to nourish the fruit, but not so much as one might imagine; and so long as that quantity is kept in good health, I do not think the fruit is in the least benefited by a further extension of growth. It should be borne in mind also that it is the first-formed leaves, that come to maturity with the fruit, upon which most depends; if they are lost or injured by disease or otherwise, the fruit will not finish in a proper manner, no matter how much young growth is produced afterwards.

J. S. W.

CULTURE OF THE PINE-APPLE FOR MARKET.

IN an early number of THE GARDEN I made some remarks on the culture and season for having Pines ripe for market, but since then times are changed, owing to the introduction of the St. Michaels Pines, which have reduced the price to such an extent that growers of Pines for market have mostly done away with them. Still, there is a season yet when we get no St. Michaels, and that is the months of July, August, and September, a time when the English Pine can be grown to its greatest perfection, and at the least cost. In order to get them ripe in the three months just named, the suckers should be taken off the old plants about the middle of February, and potted

in 7-in. pots, well drained and clean, in some good top sod of a light loamy character, full of fibre, with a good sprinkling of rough sand well intermixed with it. Pot firmly. As topsoil is often difficult to procure, I may add that Pines will succeed fairly well in any open mixture, provided it is sweet. Always avoid mixing manure with the compost, as it retains water and sours the soil. When the suckers are potted plunge them in a bed of tan, which has been prepared by sifting all the dust out of the old tan, and replacing it with fresh material; mix all well together. In this way a steady heat is maintained than would otherwise be the case, and in order to preserve the roots in a healthy condition, the bottom-heat should not exceed 85°, with a close atmosphere of 60° at night, and 65° by day. No ventilation will be required during February and March.

If the fires be properly attended to, in six or seven weeks the suckers will be well rooted and should at once be repotted into 10-inch pots, in which they should be fruited, and again plunged in the tan bed, which should have been previously forked over, keeping the atmosphere close and moist. Always avoid giving any check to the plants, as it is apt to cause them to fruit prematurely; in fact, in order to grow good fruit in the least time, the plants should never receive a check from the time in which the suckers are potted till the fruit is ripe. Watering must be carefully attended to; a short supply is apt to cause the plants to push fruit prematurely; too much rots the roots. It is best to allow the soil to get nearly dry, and then give sufficient to thoroughly wet the ball.

If the soil be fairly good no manure-water will be required before the plants show fruit, but afterwards give a regular supply in a weak state, which is much better than a strong dose now and then. Sheep or cow manure makes the most suitable liquid, mixed about two days before it is wanted. As the sun gains more power give air early, and by degrees; in a light house, with the plants close to the glass, less ventilation and less fire-heat are needed, conditions alike beneficial to the plants and the pocket. Pines should never be shaded; give air early, keep the fires low, and shut up early in the afternoon, slightly damping the plants overhead with the syringe. If the thermometer should run up to 100° no harm will be done, provided the pipes are cool. Stir the fire in time to get the pipes warm by the time the sun begins to decline, so as to maintain a steady temperature for the night, and by the time November sets in the plants will have made good growth, when a drier atmosphere must be maintained to well ripen the plants. This induces them to form a good centre of short, thick leaves, a sure sign that good fruit will be the result.

During December and January a dry temperature of about 60°, with no more water at the roots than will keep them from being dust dry, is what they require. When February sets in fill up the evaporating pans, moisten the paths, and allow the thermometer to run to from 65° to 70°, according to the state of the weather outside. Maintain a bottom-heat of from 70° to 80°. By the end of February the fruit will begin to push through the centre, when a genial, growing atmosphere must be continued by damping the surface of the bed with the syringe. Never syringe the plants overhead after they show fruit; it induces the production of large crowns. If the fruit should be coming in too early give as little fire-heat as possible. Under such conditions the fruits swell better and are longer in ripening, but it is better to have them in a little early than too late, as they can be kept on the plant five or six weeks after they are ripe in a cool, dry place. As soon as the fruit begins to change colour, ventilate freely, and maintain a drier atmosphere, which very much improves both colour and flavour.

JAMES SMITH.

Waterdale.

OUR FRUIT PROSPECTS.

THESE continue bright and fair. Seldom have all tender stone fruit trees been more thickly crowded with fine, healthy blossom-buds. The fear that the unusual severity of the past winter may have pierced through the dormant buds and injured them in that state has proved groundless. The stigma and many of the embryo fruits, as well as the stamens, seem safe and sound; they are now (April 6) fast bursting into blossom, and from the time they open till they are sheltered by the leaves and safe from the stinging severities of the late frosts of May is the season of greatest anxiety to the cultivator. With, however, anything like fine weather and ordinary skill in the application of protective expedients, it is hoped that a good crop of wall fruit may be insured. We have first applied our glass copings and a thin screen of Spruce, Yew, and other boughs, as recommended a week or so since in THE GARDEN, and feel pretty confident concerning the result; though, of course, there is many a slip in the fruit crop between April and the end of May. The wood is, however, as a rule, strong and healthy, and the buds remarkably plump and full; they are also later by several weeks than ever I remember to have seen them, and all these things are very much in their favour.

NOTES OF THE WEEK.

Pyramidal Pears and Plums seem, however, rather thin of bloom in these gardens, but possibly this may be only local. Pear bloom on walls barely seems an average crop, though many of the trees are well laden. Cherries and Apples show well, and it is to be hoped the Apple crop may prove an average one this season, for a scarcity of Apples proves by far the most serious loss to all classes of society. Other fruits may be looked upon as luxuries, more or less, but Apples as necessary articles of diet; hence, their scarcity and consequent dearth become a serious drawback to the comfort and health of the people. For Apples as food are proverbially sanitary. I had long the pleasure of knowing a chemist who was also a clever vegetable physiologist and botanist, whose only medicine for himself for years was a baked Apple. But the chief use of Apples and other fruit is to render medicine unnecessary. Apples are also nutritious, and are asserted to be highly favourable to the sustentation of brain power, by supplying the system with abundance of phosphorus and other matters. Be that as it may, one has noticed how popular Apples are among all classes, and with what eagerness children desire and devour them. The scarcity of Apples has no doubt added considerably to the sense of deprivation and distress that has so largely prevailed among the industrial classes during the past winter, and the badness of trade and the lack of money have placed the somewhat full supply of excellent American and Canadian Apples beyond reach of the purchasing powers of the working classes. It is, therefore, to be earnestly hoped that, among other symptoms of returning prosperity, one of the most cheerful and promising may be the strong probability at least, for it is yet too early to think of the certainty, of a good crop of fruit.

D. T. FISH.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Setting the Blooms of Peaches and Nectarines.—I quite agree with "D. M.'s" remark (p. 288) in reference to this subject. Provided the trees are properly pruned, the roots through the autumn and winter well supplied with manure and water so as to keep them at work, and ventilation given judiciously while the trees are in bloom, in order to dry the pollen thoroughly once every day, there need be no apprehension about the flowers setting. Should the weather be adverse, then, of course, more fire-heat is necessary, in order to obtain sufficient ventilation. I may add, that the trees here have annually, for years, carried extraordinarily heavy crops of good fruit, the result simply of proper root action, vigorous growth, and seasonal ventilation.—TROS. COWBURN, *Sunbury Park*.

Sauces for Strawberries.—A few weeks ago one of your correspondents disputed the utility of using saucers of soil for Strawberries, as recommended by me, urging that extra feeding from the beginning would produce leaves at the expense of flowers and fruit. In looking over a successful batch of Strawberries the other day previous to thinning out the berries, it occurred to me to send you two plants cut over at the surface of the pots, just to show you whether or not such a practice is attended with the bad effects stated by your correspondent. The two kinds I send you are a fair sample of about 400 plants of the same stage just now and of our early batch now over. The sample of Black Prince grew in a 4½-in. pot, and the Vicomtesse Héricart de Thury in a 5½-in. one. The first has about seventy well-developed flowers upon it, and mostly all set perfectly and swelling freely from the size of small Beans downwards; and the last has about sixty or more still farther advanced. I think I may say also that you will find that the foliage in both cases is not too vigorous, nor yet by any means unhealthy. I am not in the habit of confidently recommending any plan to your readers that I am not sure about myself, and I send you the enclosed as vouchers in this particular case.—J. S. W. [No Strawberry plants could possibly be better set with fruit than those in question, or more healthy or promising in every respect.]

Sluggish Seeds.—A quantity of seed of different varieties of *Primula amena*, sown directly it was saved last August in a shallow box and placed in a greenhouse, where it has ever since remained, is just now germinating freely, but not a single seed grew within six months from the time of sowing. This proves how necessary it is in the case of certain seeds to have patience. Those who did not understand the nature of seeds of this description would have been apt to conclude that they were dead. I have had recently a similar time to wait for the germination of home-saved seed of *Lilium auratum* sown in the autumn, but it came up well in the following summer. Whilst some seeds will germinate freely at any time, there can be little doubt that spring time is the most natural season, and hence the germination of many things that at other seasons refuse to grow.—A. D.

Chionodoxa Forbesi.—This pretty bulbous plant, a native of Asia Minor, has again proved perfectly hardy in Derbyshire, and has stood the winter without any protection in the open ground. It has been fully three weeks in bloom. *Orchis foliosa* is also pushing up strong shoots, although quite unprotected this winter.—M. S. LOVELL.

Begonia Ingrami.—Of all *Begonias* with which I am acquainted none are more serviceable for winter blooming than B. Ingrami. Plants of it here commenced flowering in October last, and the same plants have kept on blossoming, without intermission, up to the present date (April 14), and they have still an abundance of bloom on them.—J. JEFFREY, *Cork*.

Roses v. Camellias.—It is reported that in Paris a great effort is being made to revive the use of Camellias for evening wear; but white Roses are preferred because of their more graceful appearance.

Smart Frost on Saturday and Sunday mornings, and sleet on Sunday and Monday last, destroyed all leaves and stems of the early Potato crop in the neighbourhood of Penzance. Some hundreds of acres are either wholly destroyed or seriously checked, the damage being many thousands of pounds.—"Cornishman."

National Auricula Society.—The third annual exhibition of the southern section of this Society will be held in the Conservatory at South Kensington, on Tuesday next, the 22nd inst., when a very interesting display of both Auriculas and Polyanthus, in addition to the usual fortnightly exhibits of the Society, will be made.

Bongardia Ranwolffii.—This, without doubt, one of the rarest as well as one of the most beautiful of hardy plants in cultivation, is now in fine flowering condition at Kew. It is a member of the Barberry family, though remarkably unlike one, as it has a depressed, Cyclamen-like stem, from the apex of which spring the leaves, which are divided into from three to eight pairs of leaflets, each of which is again divided, presenting the appearance of being arranged in whorls. These are wedge shaped, of a pale glaucous-green hue, and each has a conspicuous reddish-purple blotch at the base, thus rendering them very attractive. The flower-stem is much branched, rising 6 in. high, and bearing roundish, golden-yellow blossoms from ½ in. to 1 in. across, which droop gracefully from slender stalks. Though now so rare, this beautiful plant is amongst the earliest recorded occupants of the garden, as it is mentioned by all the early writers on garden plants. It has a wide range of geographical distribution, as it is found from the Greek Archipelago to Afghanistan.—W. G.

A New Dracæna.—One of the most stately species of this genus that we have yet seen is one which is now and has for some time past been finely in flower in the Palm House at Kew. It is tree-like in habit, with a woody stem as thick as a man's arm, and forked at the base, each branch rising 6 ft. high and terminated by a huge head of deep green foliage, similar in appearance to the ordinary broad, green-leaved *Cordylines*. From the centre of each head is produced an immense panicle, over 3 ft. long, which branches in a candelabra-like manner and droops most gracefully; on this are arranged myriads of rather small greenish-yellow blossoms, which emit a peculiar honey-like odour. The name of this handsome novelty is *D. floribunda*, of Baker; its native country is not given. Though it possesses such imposing grandeur when in a flowering state, it can never become an object of general culture on account of the large size which it must apparently attain before it produces flowers, but when associated with other large-growing subjects in suitable structures, as at Kew, the effect which it produces is such as needs only to be seen to be appreciated.—W. G.

MR. T. BLAKE WIRGMAN has completed a portrait of Mr. Robert Marnock, which is considered by all who have seen it to be remarkably successful both artistically and as a striking likeness.

The Silver Wattle (*Acacia dealbata*).—In "Notes from Kew" (p. 209), it was stated that the large plant of this tree was then in splendid bloom in the temperate house of the Royal Botanic Gardens. It may interest some of your readers to know, that in spite of the thermometer being at 19° and 17° here at night, and snow on the ground for a week, more than once, with frost and snow again last week, a plant of the same tree here in the open air, on a north-east bank which is by no means well sheltered, is covered with bloom on every terminal shoot, and has been in full flower nearly three weeks. The plant, which is about thirty years old, was killed to the ground in 1860-61, but recovered, and is now 26 ft. high, and has produced me some healthy young plants from suckers which it threw up one season. The foliage has suffered slightly from the winter, and has lost much of its silvery hue, but it stands out in good contrast

with a large *Pinus insignis*, which forms a background to it, as seen from the windows of the house. I sent a sprig of it to Kew in March, and Sir J. D. Hooker informs me that the flower-balls of my specimen are, as might be expected, rather smaller than those under glass at Kew, and the leaf less silvery.—J. N. ROGERS, *Penrose, Helston, Cornwall.*

Notes from Vienna.—I went the other day to Schönbrunn to have a look in the houses. In these I noticed several *Acacias* in flower, such as *A. affinis*, *angustifolia*, *dealbata*, *Douglasii*, *floribunda*, *glaucescens*, *longifolia*, *lineata*, *reclinata*, and *vestita*. *Artemisia ringens*, a curious Aroid from Japan, with a brownish-coloured stem, is kept here in pots in a cool house. In England it will probably prove to be hardly. *Primula aculis*, *violacea* fl.-pl., also kept in pots, is now bearing flowers in profusion. I also noticed a small plant of *Soldanella alpina* in flower. Of Bunkins the following three species are in flower, viz., *B. spinulosa*, *Gartheri*, and *ericefolia*. I also found *Calpurnia* (*Virgilia*) *capensis* a very handsome plant, with whitish-pink flowers, in great beauty. A week ago our Wallflowers and other hardy and half-hardy herbaceous plants were planted out in the beds devoted to spring flowers. We generally have three or four kinds of Wallflowers, and as edgings we use *Alyssum saxatile*, white and blue-flowered *Forget-me-Nots*, and *Aubretia deltoidea*. *Violas* are great favourites here, especially those with pure white, light blue, or yellow flowers. We have again heavy falls of snow, and the nights are very cold, so much so as to stop all outdoor work in the way of planting. Since November last we have had snowfalls every week, and they seem very reluctant to leave us.—LOUIS KRATZSCH.

ANSWERS TO CORRESPONDENTS.

Bedding Plants.—What plants are best suited for planting round a fountain? and also for beds in a conservatory, the planting to be low, being in front of a drawing-room window.—C. A. H. [If the conservatory has a dressy character, and situated on a parterre, then the ordinary class of bedding plants will be most suitable, such as *Pelargoniums*, *Calceolarias*, and *Lobelias*, which can be replaced with small evergreen shrubs in the winter; but if of a rustic nature, then use plants such as the dwarf *Scillas*, *Scandias*, *Scutellaria*, *Telephium purpureum* type, variegated and green *Periwinkle*, and moisture-loving *Alpine* plants, such as *Gentiana aculis*. For your conservatory border, as the planting must be low, it will be best to grow the usual conservatory decorative plants in small pots, to be placed in the beds, which may be carpeted with *Lycopodium denticulatum*.—W. H.]

Camellias under Verandahs.—In growing *Camellias* under a verandah should the plants be in the ground or in tubs or pots? Is the roof of the verandah sufficient protection from frost? Should they be trained against the wall of the house? and if planted in the ground would they require to be kept watered?—QUIRIST. [Camellias will do well trained to the wall of the house, and if there be border space they will be best planted out. They should have a well-drained bottom, and at least 2 ft. in depth of soil, which should also be 2 ft. or more in width. In the summer-time, they will require copious supplies of water, and should be well syringed in the summer season if the verandah prevents the rain from washing the foliage. Nearly all *Camellias* are as hardy as common Laurels, and they will, therefore, need no winter protection.—W. W.]

Rabbits Barking Trees.—Do rabbits eat the bark off evergreen Oaks, and what remedy is best to apply to prevent their damaging any trees?—C. T. H., *Hartwood, near Margate.* [Though I have never known an instance of much damage being done either to the evergreen or common Oak by rabbits, yet I have on several occasions known them commence upon both; and during such a winter as the past one very few trees have been spared in localities where rabbits abound. With us they have attacked Fir and Pine, Holly, Ash, Chestnut, Beech, Poplar, and many other trees. After trying many mixtures for keeping rabbits from injuring young trees, I have found the following to be the most efficacious.—Take nearly equal parts of cow manure, night-soil, and quicklime, and beat them up together with water in a pail to such a consistency that it can be applied with a common whitewash or tar brush; to this add a little Stockholm tar and linned oil. Apply freely to the stems and lower branches in dry weather, and the plant so treated may be considered safe for a year.—A. J. BURNWELL.]

Propagating Camellias.—Can *Camellias* be propagated from cuttings put in next 30, amber or October like other evergreens? also can they be propagated by layers, a lot in what month? On what stocks can they be grafted?—D. H. [*Camellias* are best propagated by grafting or inarching them upon the common single red variety. The latter is obtained by means of cuttings struck in heat, or by means of seeds. The best months for striking them are in August and September. Seed may be sown at any time on bottom-heat. For directions for raising and inarching see Vol. XIII. of THE GARDEN, p. 389.]

Evergreen Ferns.—Kindly give me a list of small-growing evergreen Ferns that will live in a case outside a window during winter, facing the north-west. Would a green glass jar in any way assist me?—SUBSCRIBER. [Try *Asplenium Adnigrum*, *algum*, *A. fontanum*, and *A. marinum*; *Ceterach officinarum*, *Laetia Filix mas crispa*, *Polypodium caribolicum*, and *P. cristatum*; *Polystichum angulare parvissimum*, *Scotopendrum Wardii*, and *Lomaria alpina*. There would be no harm in having the glass of the roof slightly tinted with green, but ordinary glass would be equally good.—H. A.]

Fumigating Vines.—Would it hurt Vines to fumigate them with Tobacco paper? and until what time regards the fruit would it be safe to do it? Thrips are also making their appearance.—Z. Y. X. [Fumigation, if properly done, will not injure either the Vines or the Grapes, which may be fumigated up to the time when they begin to change colour. Spounging the leaves infused with clean water will keep the thrips in check till the crop is ripe, when more severe measures may be resorted to.—S.]

Phorium tenax in Water.—Am I likely to succeed in growing *Phorium tenax* out-of-doors in Sussex if I plant it in a basket or hamper of suitable soil, and then drop the hamper in a pond, so that the top of the hamper is 1 ft.

below the surface of the water? The roots could never be frozen, but I am afraid that the plant might rot off in the winter, although it might grow well in the summer.—E. G. L. [We have certainly seen this plant growing in water in the south of Ireland, and it is well worth a trial in that way in Sussex.]

Has Lead Wire any Injurious Effects or Not?—The effect complained of (p. 370) may be due to galvanic action. I should recommend the use of lead labels attached with lead wire as a preventive. If a piece of zinc and a silver coin be placed in the mouth, the galvanic action may be observed by a strong and peculiar taste, whereas if they be put into the mouth separately nothing whatever occurs. The action of lead and iron may be observed on old iron railings, where the lead used to fasten the iron to the stone has eaten the iron in many instances completely away. Probably galvanic action is the cause of injury to young shoots of Peach trees, through being trained against galvanised iron training wires.—BEN. ROBERT.

Camellia Sport.—In answer to "T. T." (p. 307), allow me to say that I picked last week from a white *Camellia* in the open air, about thirty-five years old, a single bloom which was entirely rose-coloured, though the flowers usually have no streak of rose, and I think I have seen the same sport on the same plant before.—J. J. K., *Penrose, Helston.*

Names of Fruit.—S. W. S.—Apparently Winter Nelis.

SOCIETIES AND EXHIBITIONS.

NEWCASTLE-UPON-TYNE HORTICULTURAL SOCIETY.

THIS is one of the oldest horticultural societies in England, having been established in 1824. During the time in which it has been in existence it has been subject to many vicissitudes, but never has it been so prosperous as it is at present. During the last few years its affairs have been in the hands of energetic business men, who work well together, and who have been successful in raising the Society to a position of eminence. There are annually three flower shows; the first was held this year on April 9 and 10 in the Corn Exchange and Town Hall, and, taking it upon the whole, it was, perhaps, the best spring show that the Society has ever held. There were eighty-six exhibitors, and the entries comprised 2187 plants staged for competition in the various classes; they consisted of 864 pots of Tulips, Hyacinths, and Narcissi. The arrangements made by the managing committee were excellent, but the exhibitors did not do their best to maintain them. For instance, some of the groups of Hyacinths were set up in a most careless manner, the tallest spikes being in front and the short ones behind, mixed up anyhow without regard to contrast or harmony of colour. As a set-off to this, some of the groups were well arranged, notably the first prize one in the class for twenty-four pots of Hyacinths. The effect of some well-grown pots of Lily of the Valley was considerably lessened by those in the back row being lower than those in the front. The use of a few blocks, on which to elevate the pots, would have been of considerable service in many cases.

One of the best features of this excellent exhibition was a collection of *Dielytra spectabilis*, consisting of a row of well-grown plants nearly as long as the room, and a very good effect they produced. It is worthy of note that this fine herbaceous plant is quite hardy in any part of the British Isles. Its pendulous spikes of pretty rose-coloured flowers were, on this occasion, quite charming. Then there were groups of *Hepaticas*, comprising the blue and double red forms only. Why cannot the single white variety of *H. triloba*, and the still more charming pale blue *H. angulosa*, also be grown and exhibited?

A class was provided for hardy Primroses, and, therefore, one would have expected to have seen the many fine varieties of *Primula vulgaris* exhibited, but this class was represented by but six small plants of *Primula amena* (Sieboldii). With the Lily of the Valley came a pretty bank of bright blue *Forget-me-nots*; then there were Wallflowers of the double German type, well grown; indeed, *Auriculas* and *Polyantuses* were shown in considerable numbers; the pretty *Spirea japonica* formed in itself quite an exhibition. *Cinerarias* were represented by several groups of good strains of seedlings, but the plants lacked training in the form of good specimens.

Stove and greenhouse plants were represented by exceedingly good specimens of *Imantophyllum miniatum*, and a very fine variety named *superbum*. There was a very good specimen of *Camellia Mathottiana* alba, with superb pure white imbricated blooms. There were also well trained *Epacris*, and fairly well bloomed examples of *Azalea indica*. Orchids were represented by the old but very useful *Oncidium spheaculatum*, the popular *Dendrobium nobile*, and the scarce but handsome *Cymbidium eburneum*, with ivory-white pale yellow-lipped flowers. *Richardia aethiopica* was represented by robust specimens having large flowers.

Passing to the room reserved for vases of cut flowers, bouquets, button-hole flowers, and cut flowers in stands, we found a most excellent arrangement, much superior to that of last year. The vases numbered fifteen, and they were well arranged, the first prize one being particularly fine; a few of them were rather overdone with

flowers—certainly a grave fault. Bouquets were very numerous, and a large proportion of them were very tastefully arranged. Cut flowers comprised Roses, Rhododendrons, Azaleas, and Camellias. These were very fine indeed, and made an exceedingly good display. Although the weather was very unfavourable, a large attendance of visitors thronged the rooms during the time when the show was open.

J. DOUGLAS.

SOME OF THE PRIMROSE FAMILY.

Of all hardy spring flowers, can any surpass in beauty or variety of hue these early favourites? From the wild Primrose by the river's brink to the last-discovered foreign-bred member of this widespread family, all are lovely. Whether these pale, delicate blossoms nestle in Moss, on sunny banks, or light the dark recesses of deepest dell in copse or covert, contrasting with Wild Hyacinth, Wood Anemone, and Dog Violet, how beautiful they are. Later, too, when the fields are dotted with yellow Cowslip, how gay the children intent on gathering the golden treasure—wealth so easily acquired, the pursuit of which brings colour to the cheek and pleasure to the heart. Cowslip, Oxlip, and Polyanthus, with their grander relatives Cyclamen and Auricula, all belong to my friends the Primrose family. There is a story told, how long ago, hard workers, gold seekers, afar in the Antipodes, walked many weary miles to see a little Primrose in flower that some home-loving emigrant had carried across the ocean to that distant land from the mother country, and how stern eyes were dimmed by tears as recollections of home and childhood awakened in the hearts of careworn, toilworn men. I do not know how the story (a true one) ended; perhaps kind deeds of love and penitence, and half-forgotten prayers sprang from those softened moods; but surely the little flower had fulfilled its mission of love, and deserved the pretty name by which the Germans know it, *Himmels Schlüsselchen* (Heaven's Key).

We must, however, leave the woods and fields (with large nosesays for homes and hospitals) and peep into the cottage gardens, gay just now with crimson and lavender and rosy-pink and deep red blossoms, all Primroses and Polyanthuses, hardy as sweet, brightening the smallest patch of garden ground, thriving in the poorest soil. Further on, even in the humblest attic window of the town, you may see a root of Primroses in a flower pot, making the dreary room gay with a scent and glimpse of country life; or, more touching sight still, in a broken glass a bunch of Cowslips, a fast fading record of a brief and hard-won holiday. To every reader of *THE GARDEN* I would say cultivate these earliest and loveliest of hardy flowers, not the single Primrose only, but the double sorts also, miniature Roses in form, and as hardy as their frail progenitors. Why these double Primroses are, comparatively speaking, so little grown is a mystery to me. Many country gardeners to whom I have spoken have never or rarely seen the double yellow, and have failed repeatedly to procure me a specimen, and many amateur gardeners have never heard of such a flower!

For arrangements of flowers for the table what is prettier than a plate or saucer filled with Moss and rows of double Primroses intermixed with pink or scarlet Pelargoniums and sprays of Forget-me-not, and fringed with fronds of Maiden-hair Fern? or, for button-hole bouquets, one or two blossoms of the white or yellow double Primrose, with purple Cineraria or *Czar* Violet? Some have double rose and double purple kinds; these are new to me, but I doubt not they will prove as lovely as their older favourites. To every one who has a garden, and delights in it, I commend again and again these freely-blooming pets of mine. Plant them now; they will neither droop nor lose their buds and blossoms on removal, even when in full bloom. Unlike their companions, the Hyacinths, they want but little care. When spring has brightened into summer they "die down," indeed, but a little leaf-mould sprinkled over the sleeping beauties is protection from the fiercest sunshine, and even Pelargoniums or other June belles planted between them serve to throw a friendly shade, and do no harm to their unobtrusive neighbours. Next year these will push their leaves and buds through January snow—promise of warmer days to come, and in themselves be some of the fairest gems in spring's fair coronet.

J. P.

THE SNOWDROP SEASON.

This year this has been the longest on record, as far as I can remember. Notwithstanding the lateness of the season, not a few of these ever-blossomed in February, and here we are at the end almost of the second week in April, yet still we are well provided with Snowdrops. Even the common single is still in flower, and the Crimean variety is in full beauty. These are not only much more graceful than the double Snowdrop, but they are likewise valuable for their lateness. In seasons like the past, when so many spring flowers are either crippled or killed, it is pleasing to turn to masses of Snowdrops

vigorous and beautiful as ever. It is surprising that more of these matchless spring flowers, which thrive anywhere, are not grown. Their roots are vermin-proof, and so are their leaves and flowers. While Crocuses are stamped out root and branch, Snowdrops are to the fore in graceful masses of unmarred beauty. Neither slug, nor snail, nor mice, nor rabbits, nor sheep, nor other ruminants interfere with Snowdrops; hence they run out of the garden into the woodland walks and woods, and all over the meadows. No flowers are more easily grown. Perhaps, however, they prefer a sheltered, partially shaded place and a lot of light warm soil, somewhat rich in humus. I have seen them thrive in all soils, from thin sand to stiff clay, and in all sites, from the semi-darkness of a thickly overhanging wood to the most exposed upland pastures; perhaps, however, they are most at home in the wild garden or in woods and plantations. In such places Snowdrops alone, or relieved with a few patches of the commoner blue early Scillas, produce artistic results beyond reach of all the more formal combinations of more expensive and formal art. The spring Forget-me-not (*Myosotis dissitiflora*) is also, in ordinary seasons, a good companion for Snowdrops, but this year, speaking broadly, this beautiful plant has failed. Of course the term failure is not applied absolutely. We have many hundreds of it struggling into blossom; a great many of these, however, are somewhat brown and patchy. That condition in April is called failure, and it is, compared with the display of azure beauty with which this lovely Forget-me-not has been wont to overspread beds and borders at this season of the year, or rather a month earlier, in the heyday and pride of the Snowdrop season. After flowering, a partial fading of the leaf is the best time for dividing and multiplying Snowdrops. The practice of keeping the bulbs out of the soil is not, by any means, one to be commended; far better divide and plant at once. The bulbs will thus be kept plump and fresh, and be able to start in good time next year without risk or trouble. Plant six roots in a patch 6 in. deep; single bulb planting rather tries the patience of cultivators, but patches of six will at once, or soon, swell out in masses of sufficient magnitude to bear further sub-division. Any soil will grow them, but could a spadeful of light earth composed of equal parts of sandy loam and leaf-mould be added for each grouplet of plants, they soon, by the superior strength of their flowers and the more rapid increase of bulbs, would show they were not insensible to the care of the cultivator. But this may be called one of the refinements of cultivation rather than a necessary adjunct to the successful culture of the Snowdrop, either in the garden, wood, mead, lawn, or by the side of woodlands, roads, or walks.

D. T. FISH.

PROPAGATING.

GENETYLIS (HEDAROMA) TULIPIFERA.—This is easily increased by means of cuttings, made of the side shoots, put in in April and May. The pots for their reception must be prepared, so as to allow $\frac{1}{2}$ in.

from the rim for bell-glasses to stand on. The soil should consist of half peat, and the other half clean yellow loam and silver sand sifted fine and pressed into the pots, which must be well drained, rather firmly. Make the cuttings as shown in the accompanying illustration, put them in firmly, and give a good watering. After the lapse of an hour or so the glasses may be put on, and the pots placed on a gentle bottom-heat (a tan bed is best). In order to obviate an excess of moisture, the glasses should be taken off and wiped every other morning, an operation which must receive particular attention, or the leaves will fall off. As soon as the cuttings begin to grow, tilt the glasses daily for a few hours, and by degrees they may be left off altogether.

The young plants thus raised will be ready for potting off and placing in a shady, cold frame in August, keeping them close and shaded from sunlight.

H. H.

Aucuba Berries.—"J. G." (p. 259) says that *Aucuba* flowers may be readily fertilised by planting a male *Aucuba* in a bed or anywhere within the radius of a few yards. I have about 200 female *Aucubas*, and about a dozen male ones planted amongst them, but I have never had a single berry. My male plants always flower long before my female ones. The male ones are now in full bud, but the female plants are not showing their buds yet. Is my experience in this respect exceptional? If not, what explains "J. G.'s" success, and that of previous correspondents, who, I have observed, have written similarly? It may be said I might save the pollen, but that is not the point. I find some difficulty too in doing that, for there seems to be very little pollen indeed; so little that it can scarcely be collected. Is my experience again exceptional?—W. H. TILLET, *Sprovestonbridge, Norwich*.

"This is an art
Which does mend Nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CHILDREN'S GARDENS.

THERE is a period in the life of every boy and girl when they feel a desire to have a garden to plant and cultivate with their own hands. This desire may assume various shapes, according to the nature or disposition of the child, and with some perhaps may only be of a fleeting character. But, making every allowance for the fickleness of youth, enough of sterling thoughtful material remains to produce, if properly utilised, an influence for good, not only on their own lives, but also on all with whom they may come in contact. Gardening, or the cultivation of plants and flowers, will not act upon all alike, neither will its benefits be conferred upon all in the same degree; but I am convinced, from early experience, and what has come under my observation since, that if, during a boy or girl's early life, a love of gardening were encouraged, it would develop into one of their greatest pleasures. In the same way as the trained eye can see in works of art, such as paintings and sculptures, beauties that are hidden from the untrained, so also the man or woman who has in early life learned to know and love plants and flowers will derive more refined and lasting pleasure from the frequent changes that Nature is continually spreading out before them than they otherwise would do. Give young people but a yard or two of ground to cultivate in some shady corner and they will be contented. What if they do frequently transplant the Primroses and Daisies which they bring in from the banks and hedgerows in accordance with their changeable whims and fancies; they are gaining knowledge; they are learning something of the mysterious workings of Nature, the study of which never cloys or wearies.

One of the most interesting children's gardens which I have ever seen was situated in a dingle or dell, and would now, I suppose, be called a wild garden. Though the period to which I am referring is something more than twenty years ago, yet the scene rises before me as vividly as if it were but yesterday. It had thickets of Thorn and Birch, where the nightingales sang and reared their young. Open, sunny spots were there, too, where many rare kinds of indigenous plants flourished, and around which lingered many pleasant associations. There were shady spots for Ferns and other shade-loving plants, and banks whereon the wild Thyme grew, emitting, when brushed by the feet, a pleasant odour. Where the shade was dense the ground was carpeted with the brightest, freshest Moss, and, to make the situation absolutely perfect, a babbling brook meandered through the valley, overhung in places with Brambles and Willows, its course being occasionally broken by piled-up boulders or other impediments, that gave louder voice to its music and buoyant life to a most charming spot. Such situations for children's gardens can only be found in the grounds of the wealthy, but I am convinced that any one with an eye for such matters could easily find positions in semi-wild spots where the hand of Nature has already laid the foundation for interesting gardens for children, where they might—encouraged occasionally with a kindly guiding word—work them according to their own ideas. Girls especially would find this kind of gardening instructive and interesting.

Many of our British wild flowers are as beautiful as expensive exotics. What banks of Primroses, Violets, Bluebells, and Lily of the Valley might be had! and the hardy species of Geraniums are quite as interesting, if not quite so showy, as the glaring-coloured *Pelargoniums* common in the parterre. What a sight masses of Snowdrops, Anemones, and Wood Anemones would present early in the year! When left long in one position they become naturalised and flower all the better for it. In an article of this kind one cannot notice a fifth part of the beautiful wild flowers that might find a congenial home in such a garden, nor yet set forth the interest which the collecting and bringing home the plants would excite in the minds of the young. How easily, too, and pleasantly might a competent teacher, under such circumstances, incite a desire for and afterwards instil into the youthful mind a knowledge of the science of botany, which, too often, as commonly taught, is but a dry study, not very enticing to the youthful of either sex. Most of the work would be light, and such as children could do with a little kindly, unobtrusive guidance. In but few cases would a man's labour be required after the place was laid out. Such a garden would annually grow in interest from the additions made to it, both in plants and seeds, until not only children, but older people might be seen wending their way in the direction of the children's garden. There must be a good dry

path leading to it and through it, and it must be so laid out as to embrace the prettiest spots and views. In our climate there are many wet days, and a garden that could only be entered in dry weather would not satisfy the impetuous youthful mind. Arbours and bowers covered with creepers and furnished with rustic seats would come in due course, as one of the earliest efforts of man, both civilised and savage, is to build himself a shelter after his own peculiar fashion on or near the spot which he cultivates.

The foregoing sketch only illustrates one phase of gardening for children, but there are many others which can now be only glanced at. The bold, resolute boy, desirous of acquiring distinction as a cultivator, might be indulged with a plot of ground in some conspicuous portion, where a feeling of pride would impel him to be energetic and industrious. In this way the dispositions and impulses of children might be directed into a good channel, and even their very failings drawn upon to strengthen their moral nature. If we descend lower in the social scale, many of the artisans' and labourers' children would take to gardening if permitted and encouraged to do so; I have, indeed, often seen more enthusiasm among this class of children in their gardening operations—generally under difficulties—than in the case of those of a higher rank in life.

But, apart from the influence that a care of, and love for, flowers is capable of exercising over a child's future, there is the further most interesting study of insects and their modes and habits of life, and the work which they do. Some of your readers are doubtless acquainted with the works of De Saint Pierre, a genial, kindly French writer upon natural history of the last century, and the description he gives of the thirty-seven species of insects that visited a single Strawberry plant standing in a pot outside his window in Paris during a very short period. The earth, air, and water teems with life, of which but little really is known. The cultivator, from sheer force of circumstances, becomes acquainted with most of the insects that are injurious to the plants which he cultivates, but he knows comparatively little of the myriads of beautiful insects that have work to do in the world, and are doing it almost unnoticed by us. Space will not permit me to say anything of the advantages to be derived from children being encouraged to take an interest in gardening from a utilitarian point of view, although a good deal from this standpoint could be said in its favour, and the time may perhaps come when practical horticulture may either be taught in existing schools or else special schools be established for the purpose. It appears to me certain to happen in the future, that the production of fruit and vegetables will become a more important industry than it is now.

E. HOBDAY.

NOTES FROM KEW.

Hardy Plants.—Some exquisite little Alpine Saxifrages are thriving admirably on the recently-constructed rockery in the herbaceous ground and several are finely in flower, amongst which the most noteworthy are the *Aretia*-like Saxifrage (*S. aretioides*), a charming kind, which grows in dense, hoary, cushion-like masses, and which is now bespangled with numerous bright golden blossoms, each $\frac{1}{2}$ in. across, borne on stalks $1\frac{1}{2}$ in. high; similar in appearance to the foregoing, but with white blossoms, and equally desirable is *S. valdensis*. The *Diapsalis*-like Saxifrage (*S. diapsaloides*) is another gem, with its silvery flowers terminating the cylindrical hard tufts of hoary leaves. *S. Rocheliana* is certainly one of the most satisfactory and easiest kinds to grow, as it rapidly spreads into large patches, which, throughout the spring, are enlivened by sparkling white flowers. Vandell's Saxifrage (*S. Vandellii*) is yet a rare kind in collections, but perhaps it is scarcely distinct enough from *S. Burseriana* (of which some consider it a variety) to allow of its being sought after; in habit it is apparently between *S. Burseriana* and *juniperina*, but it has the large white blossoms of the latter kind. The rare *S. flagellaris* is flowering finely, and its bright yellow blossoms, which are large for the size of the plant, are very attractive; its leaves grow in rosettes, which throw off in all directions slender runners that quickly take root, thus increasing very freely. It is remarkable also as belonging to the few flowering plants which grow at the highest latitudinal limit of vegetation, as it is found only in Arctic North America and at lofty elevations on the Rocky Mountains. The numerous kinds of Grape Hyacinth (*Muscari*) are now beginning to make an effective display in the hardy bulb collection, and amongst them are several new kinds. *M. Szovitzianum* is a very handsome sort which bears dense racemes 2 in. long of bright clear blue, sweet-scented flowers; it is a native of the north of Persia. *M. Pinardi* is another beautiful sort that bears even longer and denser racemes of blossoms than the last, but they are of a much darker hue. *M. micranthum* is apparently the smallest of all the cultivated *Muscari*, but it is none the less interesting, especially as it is the sweetest scented of them all. The best of the older kinds to be found at Kew include the lovely *M. Heldreichii*; a native of Greece

with its clear blue clusters of flowers, the minute teeth of which are pure white, thus considerably enhancing the effect. The pale-flowered form of *M. botryoides* is quite unsurpassed in point of colour; the soft sky-blue tint of the blossoms contrasts admirably with its pure white neighbour (album), and the deep purplish-blue shade of the type and the other kinds. This variety seems to be rather scarce in gardens, but it should be the aim of all hardy flower lovers to possess such a desirable plant. The Leopard's Banes (*Doronicum*) are handsome, early-flowering Composites of neat habit, and remarkably floriferous. They all have yellow flowers. The most desirable kinds are *D. austriacum*, with heart-shaped leaves and flowers 2 in. across, and *D. caucasicum*, a kind more slender in growth and with smaller flowers. The short-stemmed *Hutchinsia* (*H. brevicaulis*), an inhabitant of the Swiss Alps, is a rare Crucifer. It differs from the better-known *H. alpina* in having much shorter flower-stalks; hence it is more compact and tufted in growth. The showy Toothwort (*Dentaria digitata*) is another handsome Crucifer, which grows about 1 ft. high, and has leaves cut into five narrow segments. The flowers, which are large, are rich purple, and produced in flat racemes terminating the stem. For partially-shaded borders this fine plant is very effective. It is a native of central Europe. The Twin-leaf (*Jeffersonia diphylla*) is a very interesting and rare member of the Barberry family, its leaves being cleft into two lobes. The flowers, which are white, measure 1 in. across, and have a central tuft of yellow stamens. It strongly resembles the Bloodroot (*Sanguinaria canadensis*), another singular and pretty plant also in flower. Both are natives of North America.

Hardy Shrubs.—Few shrubs are at present more interesting than the showy *Ribes* (*R. speciosum*), the flowers of which resemble those of a *Fuchsia* in form, and the graceful drooping manner in which they are produced renders them remarkably distinct; they are bright red in colour, 1½ in. long, and are produced plentifully in succession for a considerable period. It is perfectly hardy, though a native of California and other parts of North-west America. *Rubus spectabilis* is a very showy Bramble with large wrinkled leaves, and flowers, 1 in. across, of a deep magenta tint. It inhabits shady woods near streams on the north-west coast of North America. Another handsome North American shrub is *Nuttallia cerasiformis*, which, in style of growth and flowering, is very similar to that most beautiful of all spring flowering shrubs, *Ribes sanguineum*; but its pendulous racemes of blossoms are white. *Prunus triloba*, a handsome Rosaceous shrub from China, is an object of much beauty at the present time, being literally covered with lovely rosettes of double blossoms, varying in colour from almost white to deep pink.

Greenhouse Plants.—On entering the east door of the Temperate House a large plant of *Holboellia latifolia*, from the Himalayas, covered with a profusion of blossoms, attracts attention on account of the delicious odour which they exhale; they hang in clusters amidst deep evergreen foliage, but, in point of colour, they are somewhat inconspicuous, the pollen-bearing flowers being pale green and the seed-bearing ones of a livid purple hue. It is, however, a most desirable climber for adorning the roofs of conservatories. Amongst Himalayan *Rhododendrons* may be noted *R. campylocarpum*, a kind which has deep crimson, funnel-shaped blossoms, conspicuously spotted with black. The hybrid variety *Princess Alice* is another beautiful kind, which has large white flowers. Though surrounded by a host of handsome garden varieties, the old *Camellia reticulata* is worthy of note; its huge rosy blossoms, with bright golden centres, are very attractive. The variegated-leaved variety of the old *Kerria japonica* is one of the most pleasing shrubs imaginable, and, when studded with a profusion of orange-coloured blossoms, it is highly ornamental. It is perfectly hardy, having withstood the past winter with impunity, but its variegation appears to be shown to better advantage under glass than out-of-doors.

Stove Plants.—The greatest ornaments among the smaller subjects in the Palm house are two East Indian *Eranthemums*, which, on account of their remarkable beauty, should be in general cultivation. In style of growth they are similar to *Plumbago rosea*, and produce their blossoms in the same long, one-sided, raceme-like manner. *E. cinnabarinum* is the finest. It has ovate leaves and blossoms 1 in. across, of a rich violet tint with a darker blotch in the centre of the upper petal. *E. purpurascens* has narrower leaves than the last, and rather smaller flowers. A variety of the old favourite *Justicia carnea*, named *superba*, shows an improvement on the original both in point of colour and size of blossom. *Burchellia capensis* is noteworthy on account of the reddish-orange colour of its tubular flowers, which are collected at the tips of the stems in dense clusters. Belonging to the same family is the *Gardenia florida*, which, in its double form, is so highly esteemed on account of its perfume. One would hardly imagine that the original plant was the parent of that which bears such large double flowers, as in the original plant they are small, and the corolla is four-cleft. Such a change shows

what skilful culture may effect in course of time. A very handsome form of *Crimum australe*, named *canaliculatum*, is a very conspicuous object; it has stately, broad foliage, and bears huge umbels of pure white flowers, 4 in. to 6 in. across, which are sweetly scented. It is a matter of regret that the exquisite beauty of the South American *Cypellus* should be so fleeting, as they present a striking feature when in perfection. *C. gracilis*, an Iris-like plant, has branching stems that bear blossoms in, across; their outer petals are pure white, while the inner ones are of a rich indigo-blue shade, and the lower ones are elegantly barred with brown. It is a native of Brazil. W.

NOTES OF THE WEEK.

Schomburgkia tibicinis at Kew.—The flowering of this, the very handsome Cow's-horn Orchid of Honduras, is an event not to be overlooked by Orchid lovers, not only on account of its shy-flowering propensity, but also for the rare beauty of its blossoms, which are undoubtedly the finest in the genus. The stems, which grow from 12 in. to 18 in. high, are about the size and have the same peculiar curve that a cow's horn has; they are, too, as hollow and smooth inside as a Bamboo, and are used as trumpets by Indian children in Honduras; hence the origin of its specific name. At the base of each stem there is also invariably a small hole leading to the interior, which furnishes access to colonies of ants, which infest the plant in its native habitat. The leaves are from two to four in number, terminating the stems, and are large, oblong, and leathery in texture. From between these the flower-stem rises several feet high, though in the Kew specimen it measures but 3 ft., and bears from six to a dozen blossoms, 2½ in. across. The wavy-edged sepals are of a deep rose colour, speckled with white on the outside and rich chocolate-red within. The lip is sandal-shaped, deep rose outside, pale within, and pencilled with chocolate-red streaks. The whole flower is of very firm texture, and under favourable conditions lasts in perfection for several weeks.—W. G.

Dendrobium barbatulum.—The more we see of this charming Orchid the more we are convinced that eventually, when it becomes better known and less rare, it will prove to be among the most valuable of this beautiful family, especially for cutting purposes, for which the arrangement of its pure white blossoms admirably adapts it, as they are borne in dense racemes on slender gracefully arching stalks from the tips of almost every stem. Like most other Orchids, the flowers are variable in point of size and form; in some they are only 1½ in. across, with broad segments and an almost heart-shaped lip, and a faint blush tint may be detected in them; in others they are larger, with the segments much narrower and the lip extremely so, and of the purest white, with nothing to mar its chaste beauty except the golden hairy fringe at the base of the lip. For its free-flowering tendency and the length of time during which it continues in perfection, and flowering, as it does, at a time when the majority of Orchids are on the wane, we should consider it invaluable for growing for market purposes, and doubtless those concerned in that direction will ere long avail themselves of it, if they have not done so already. The very effective display made by this Orchid alone now in the Orchid house at Kew is quite sufficient to recommend it.—W. G.

Azalea Empress of India.—We have received from Mr. A. Van Geert, Ghent, a coloured illustration of this new double-flowered Indian Azalea, the blooms of which are as remarkable for size as for their striking colours, which are rosy salmon spotted and boldly edged with white. At the International Show held at Ghent in April last year, this Azalea obtained a first prize under the provisional name of "Héros des Flandres," and on the 11th March last it obtained a first-class certificate at South Kensington. It is compact in habit, a free flowerer, and will certainly make a first-class plant both for market and exhibition purposes.

Hardy Flowers at Eastcott.—The sharp frosts, heavy showers, and snowstorms of last week have together severely affected herbaceous and rock plants, but the following are in full flower and uninjured, notwithstanding the weather, viz., *Muscari botryoides album* and *ceruleum*, *Puschkinia libanotica*, *Primula nivalis*, *Narcissus bicolor* Horsfieldi, *Anemone fulgens*, *Gentiana verna*, *Hutchinsia alpina*, *Saxifraga*, *Epimedium*, *Androsace*, *Omphalodes verna*, and *Draba*.—A. K., Eastcott Cottage, Pinner.

Crystal Palace.—We regret to learn that Mr. George Thomson, the very capable superintendent of the Crystal Palace Gardens, has resigned his situation in that establishment. Those who have seen how well he has managed all departments of the gardens there with a very much reduced staff will regret that the and wish Mr. Thomson a fitting sphere for the exercise of his abilities.

Rhododendron Nuttalli.—I have now in my winter garden a plant of this *Rhododendron* bearing thirteen trusses, each consisting of from five to seven flowers. The largest truss is 13½ in. in diameter, and the single flowers are large in proportion. The plant, a seedling from the first that flowered in Europe, is comparatively young, and proves that this superb *Rhododendron* is not a shy bloomer, though generally supposed to be so.—O. F., *Augsburg, Bavaria.*

Mr. W. GOLDRING, for some years Superintendent of the Herbaceous and Alpine Department of the Royal Botanic Gardens at Kew, has resigned that position, and joined the staff of THE GARDEN.

THE INDOOR GARDEN.

TREE FERNS AND ORCHIDS.

EPHYTAL Orchids and Tree Ferns are found as co-partners in the forests of both hemispheres, and the latter are especially beautiful as seen in the form of groves besides streams, on mountains, or on hill-

Tree Ferns, Bromeliads, and Orchids.

sides in the Tropics. In the East, some species having stems from 20 ft. to 30 ft. in height are not uncommon, and they may be readily distinguished from all other types of vegetation, not only by their form, but by the delicate tints of fresh green colour which their ample fronds possess. The finest of all Tree Ferns in size are doubtless the *Dicksonias* of Australasia, but in grace of frond and slender-stemmed elegance of port, some of the Eastern species far surpass them. Naturally they exist in groves, and the charms which they possess when so seen is due to their variable size and the curious positions in which they grow. Here they root into the earth, and their great umbrellas of plummy fronds are borne aloft on the straightest of stems. I have seen a little colony growing on a large sandstone rock, their masses of black hair-like roots forming a perfect mat of fibres over the surface of the mossy stone, while close by were a pair of specimens which had rooted on a large tree trunk 20 ft. above the ground level. The spores had germinated there, and it was curious to see the way in which their stems were curved, so as to allow room for their spreading

plumes. Tropical forests are, however, monotonous in effect after a little acquaintance with them; their tints are less variable than those of our own woods, and if any strikingly beautiful views be obtained in them, one is almost sure to find the effect due either to groves of Bamboo or Tree Ferns in the foreground or middle distance. Although generally found in wet, or, at least, moist and shady places, still Tree Ferns will not unfrequently flourish in full sunshine, nor do their fronds suffer, as is the case sometimes at home, especially when the soil in which they grow is allowed to become too dry. Naturally, their roots can ramble about under Moss and stones or tree roots, and very often they reach the water near them, and so can defy the power of even a tropical sun. Moreover, a mass of dead leaves and other debris is sure to congregate around the base of their stems, and so the roots are always comparatively cool and moist. Tree Ferns at home suffer not so much, however, from dryness at the root as that of their stems, and in order to remedy this some wrap Sphagnum Moss around them, while others syringe them two or three times a day. What one most admires in a tropical forest is the utter abandon of Fern and Orchid beauty, as seen amongst the branches of Moss and climber-draped trees. In the East this is especially so, and in South America the Orchids have often to fight their battle of life with epiphytall Bromeliads of many kinds, some of which are quite as beautiful as their more fashionable neighbours. We generally try to meet the wants of epiphytall Orchids by growing them on blocks in our Orchid houses, but in the case of the majority of epiphytall Bromeliads we give them ordinary pot culture, and they simply have to make the best of it. In Stevens' auction rooms the other day, however, a plant of the beautiful *Odontoglossum vexillarium* and others of O. *Alexandre* were pointed out to me, which had been potted in ordinary garden earth, just as an artizan would pot a Fuchsia, and yet singularly enough both species had made larger bulbs and leaves than those of the previous year. In their wild state one may often find both Orchids and Tree Ferns growing in stiff yellow loam, sometimes in clay itself surfaced with sandstone grit, and if peat earth be found it is generally accompanied by dwarf and scrubby vegetation, whereas at home. Of course, peat has its specific value for Heaths and similar plants, but for strong-growing Orchids and Tree Ferns a trial of rough fibrous loam is much to be desired. That *Cypripediums* and *Cymbidium* will succeed in fibrous loam, from which the small earthy particles have been sifted, is a well-known fact, and I am convinced that many *Cecylogenes* and semi-terrestrial Orchids generally may be grown in a well-drained compost of fibrous loam, leaf-mould, and coarse sand with perfect success. The accompanying illustration gives one an excellent glimpse of the graceful contour of Tree Fern fronds, as seen spreading above a tangled group of Bromeliads and long-bulbed epiphytall Orchids in their native habitats. The drooping character of the dead fronds is very faithfully rendered by the artist, as are also the chaffy and paleaceous bases of the large stipules; indeed, the sketch may be taken as an example of how readily a few judicious touches with the pencil on 1 or 2 square inches of boxwood may be made to give one an idea of graceful vegetation, and to define different classes of plants with almost photographic accuracy. B.

CONSERVATORY CLIMBERS.

Tacsonias.—Nothing adds so much to the ornamentation of a conservatory as climbers, among which there are now some very fine plants, the most recent introduction of note being *Tacsonia exoniensis*, a hybrid between *T. mollissima* and *T. Von Volkemi*. In habit it is intermediate between the two parents, and the flowers partake in about the same degree of the character and colour of both of them. This *Tacsonia* is both beautiful and a remarkable free grower. The only drawback to climbers of this class is their liability to scale, which clings so tenaciously to the bark, that it is not an easy matter to destroy or dislodge it. In appearance these pests are not unlike small splashes of whitewash, and are to look at just as inanimate, for one can never detect any movement in them with the naked eye, and yet somehow or other they manage to spread at a great rate, and soon cover the entire bark of the stem from one end to the other if undisturbed. In order to get rid of scale, the first thing is to prune out all that can be spared, which in most cases will be the entire shoots made last summer, as, like most climbers, *Tacsonias* flower on the young wood; the object, therefore, should be to make way for this, and give it all the encouragement possible. To remove the scale, a solution of Fowler's Insecticide is as good as anything, which, used in the proportion of five ounces to a gallon of soft water, and well rubbed in with a brush, so as to wet the whole, is sure destruction to the insects. In growing and training these *Tacsonias*, there is no way in which they do so well, or show themselves off to such advantage, as when run up to the roof and allowed to depend therefrom, very much in their own natural manner, except, of course, that they should not be allowed to grow wild and become

an entangled mass, but thinned out, and not tied formally or at all if it can be avoided, as then they droop gracefully down, furnished with their trumpet-shaped blossoms, and look quite at home. The soil in which they do best is a fibry loam cut from an old pasture, and the fresher it is used the more they like it, besides which, it lasts in an open condition longer, and is therefore more desirable on that account. In order to grow these and other climbers well, and keep them in a vigorous, healthy state for a lengthened period, it is necessary that they have plenty of root room, such as is afforded by a good border, for although they may be grown in large pots or boxes for a time, they never attain that degree of strength or flower so freely as they do under more liberal treatment. One climber, however, is an exception to this, and that is

Tecoma jasminoides, which requires pinching in order to check any undue redundancy of growth, and cause a ripening and hardening of the long, twining shoots it forms, without which the blooms are few and far between; but when restricted and fully exposed to the influence of sun and light, it is one of the most useful and ornamental conservatory climbers that can be had, as it is a fine evergreen, with foliage that never looks shabby or becomes infested with insects.

Passifloras.—Of these, all the greenhouse kinds are very desirable, resembling in habit the *Tecomas*, with which they associate well and form most elegant roof garniture. Another great thing in favour of the *Passion* flowers is that they are quite proof against insects, for, although I have had to do with them for a great number of years in houses where others do not escape for long, I never knew any of them affected, and this immunity renders them doubly valuable for planting in situations where they cannot well be got at. The treatment requisite for them is much the same as that recommended for the *Tecomas*, so far as pruning and training are concerned, but, being remarkably free in the way of growth, almost any soil will suit them, so long as they receive plenty of water, of which, if properly drained, they cannot have too much during the three summer months. The sorts best adapted for conservatory decoration are *P. racemosa* *corulea*, *P. Mayana*, *P. Colvilli*, and *P. Count Kisselkeff*; the first of these is nearly hardy.

Mandevilla suaveolens.—Were it not for being deciduous and so subject to green fly when making its young growth, *Mandevilla suaveolens* would be much prized as a climber, on account of its pure white, Convolvulus-shaped flowers that are borne in such profusion, but, unless it can be fumigated, it is useless attempting its culture, and as conservatories generally adjoin the dwelling-house, it is not easy to do this without creating a nuisance.

The Lapagerias.—For a shady, damp wall, where a trellis can be placed, or some wires strained vertically, or for a low structure not much exposed to the sun's rays, nothing can equal the *Lapagerias*, the red and white varieties of which grown so as to intermingle together have a most charming effect, the one helping to set off the beauties of the other to advantage. I have heard many complaints of the great difficulty experienced in getting plants of these *Lapagerias* to start and do well, a failing generally owing to a want of proper preparation of the border in which they are grown, and when this is suitably made, they start away with great freedom, and soon become thoroughly established. Requiring, as they do, immense quantities of water when flowering and making their growth, it is a matter of the greatest importance that plenty of drainage should be provided, otherwise the soil loses its healthy texture, and is rendered sour and inert, a condition that is highly unfavourable to the roots. Soft red brick broken in pieces about the size of Walnuts is as good as anything to drain with; 6 in. of this will not be any too much, and if on these some sods of peat are laid at starting they will keep the interstices clear for years after. In the filling up of the remaining space, which should not be less in depth than from 18 in. to 2 ft., the same kind of material should be used, only chopped up a little, as it cannot well be too rough, and to keep it open and porous a good sprinkling of silver sand is necessary. In this mixture I have found *Lapagerias* to thrive well. They are somewhat difficult to move or interfere with, unless it be done just as they are commencing their growth, as at that season, if they are well watered and kept syringed for a time, they may be transplanted with safety. In turning them out of their pots, it is always advisable to remove as much of the old ball as can be done fairly, so as to disengage their roots, which are then at liberty to take possession of the new soil, and, this being fresh to them, they lay hold of it with avidity. The great thing is to begin with good, healthy plants, which, though they cost a little more, are the cheapest and best in the end. They can only be raised from layers or cuttings to be depended on to come true to name. Unfortunately, slugs have a great partiality for the young shoots. A battery, made by means of a strip of zinc and copper, the two metals being brought in contact, forms a safeguard if placed around the collar of the plant, and a broken lamp glass is a good protection for any young shoot that may be just making its appearance aboveground. Those who may be desirous of increasing

their stock of *Lapagerias* will find this to be a good time for layering; to get them to root, all that is needful is to bury the stem of the shoot about 3 in. deep, and allow the branches or points leading from it to have their tips out so as to keep up a circulation and maintain life in the whole. The hardness of these magnificent climbers is such that they will succeed in any house from which frost is excluded, and the damper and cooler the atmosphere the better it suits them.

Rhynchospermum jasminoides.—For clothing pillars nothing is better adapted than this, and it is a plant that bears pruning well, and will readily conform to any method of training that may be necessary to cover the space allotted to it. Exposed fully to light and sunshine, so as to ripen its growth, it flowers with great freedom, and, being so sweet-scented, it quite fills a large house with its odour. Either loam or peat, or a mixture of the two, suits it, as it is not at all particular as regards soil, but does best in that in which there is plenty of grit, and it should be made firm, as compression induces a short, sturdy growth and a more floriferous habit.

Hadrothamnus elegans.—For covering a large breadth of wall, where it can be trained flat and allowed to form breast wood, *Hadrothamnus elegans* is a grand plant, bearing, as it does, long racemes of tubular blossoms that hang down from the ends of each shoot in a most graceful manner. In a house kept somewhat warm, and planted out where it can have plenty of root-room, it flowers almost continuously the whole year round. To aid it in doing so, all that is necessary is to remove the spent growth and keep the plant supplied with a little liquid manure at each alternate watering or so. Being of rather a gross feeding habit, the border intended for it should consist of rich soil, such as good fibry loam, the turfy sods of which, chopped up roughly, soon help to push it along.

Jasminum gracile is likewise a capital plant for the same purpose, and one which rapidly fills a large panel; or it may be run up into the roof and used as a climber. The foliage of this *Jasmine* is about the size of that of a *Myrtle*, but much thinner, and the flowers are small, white, and star-shaped, hanging in clusters, and strongly scented. S. D.

THE COFFEE SHRUB.

At the present day the Coffee shrub is cultivated throughout the Tropics, but its native country is the mountainous regions at the extreme north-west point of Abyssinia, the word Coffee being derived from Caffa, the name of one of the provinces of that country. From Abyssinia the Coffee was first introduced into Arabia by the Arabs, and cultivated in Yemen, or Arabia Felix, as it was anciently called, and for upwards of two centuries Arabia supplied all the Coffee then used. Towards the end of the seventeenth century, however, the Dutch succeeded in transporting it to Batavia, and from thence a plant was sent to the Botanic Garden at Amsterdam, where it was propagated, and in 1714 one was presented to Louis XIV. The credit of introducing the Coffee shrub into the Western Hemisphere is a disputed point. One story asserts that the French introduced it into Martinique in 1717, while, on the other hand, the Dutch are said to have previously taken it to Surinam. In either case it is certain that we are indebted to the progeny of a single plant for all the Coffee now imported from Brazil and the West Indies.

This above short but explicit account was written by the late Mr. Alexander Smith, the first curator of the Economic Museums at Kew. Like that of many other beverages and forms of vegetable food, the first account of the use of Coffee is lost in obscurity, and wherever it has been introduced, it has always at first met with much opposition. Until quite recently the best Coffee came from Mocha by way of Aden, but now the methods of preparing the berry are so much improved both in Ceylon and elsewhere, that Mocha Coffee has nearly lost its once high character. The plant producing this grateful beverage is a glossy-leaved shrub, nearly allied to *Ixora* and *Cinchona*; it attains a height of 10 ft. or more, and the part used is the seeds or "beans," two of which are produced by a red berry nearly as large as a cherry, the berries being preceded by white flowers clustered in the axils of the leaves. Until quite recently only one species (*Coffea arabica*) was generally cultivated as yielding Coffee, but now another larger growing and more productive kind (*C. liberica*) is being planted in Ceylon and elsewhere in Eastern plantations. Apart from its larger berry and greater productiveness, however, the new plant is said to be amenable to successful cultivation at a lower altitude than is possible with *C. arabica*, so that much land below 1400 ft. may now become available for Coffee culture, which, previous to the introduction of the Liberian variety, had to be employed for the growth of less productive crops. A great drawback to successful Coffee culture in Ceylon of recent years has been a peculiarly subtle and destructive leaf disease, the only effective remedy for which is plentifully manuring the land. Again, plantations have become worn out, and virgin land is not now so readily attain-

able as formerly, hence we find pioneers out all over the Malayan archipelago prospecting for suitable Coffee estates. Already plantations have been commenced in Perak, and also in Lahore, the mainland immediately behind the town of Singapore, and the most satisfactory accounts have been published of the suitability of the highlands of North Borneo for this particular industry. In Malacca, Sumatra, Borneo, Java, and the Philippines the Coffee shrub is found around the native huts, where it exists and affords a moderate supply of berries without any especial system of culture; but, for its profitable growth as a sale product, not only is the best of red loamy soil—if with boulders and Bamboo clumps in moderation, so much the better—required, but the culture and preparation are laborious throughout, and bad weather during the harvesting and drying of the crop often, by damaging the produce, lowers the profits considerably. Unless systematically cultivated, the crop produced is a straggling one, and thus much labour in collecting the berries is wasted; hence, one great object in the cultivation of the Coffee shrub is to obtain a simultaneous crop. The berries are gathered when ripe, and a pulping machine through which they are passed removes the outer coat, after which they are immersed in water vats for twenty-four hours to

nor ground at all until wanted, if it can possibly be avoided. The leaves as well as the berries contain caffeine, which is the essential principle of this product as a beverage, and in Sumatra the natives of some localities prefer an infusion of the leaves to that of berries prepared in the usual way. Its value as a beverage depends on its two-fold action, as a soothing of the vascular system, while it acts as a stimulant to the brain, and its value as food is negative rather than otherwise, since it prevents undue waste of tissue rather than actually affords any nutriment to the body.

Brazil, and Ceylon, and British India, have hitherto been the great Coffee-producing countries. In 1875 the total imports were 1,589,732 cwt., of which 750,055 cwt., of the value of £3,743,505, were from Ceylon; in the same year from Brazil 222,375 cwt. were imported, of the value of £961,470; from Aden the imports were 15,058 cwt., of the value of £78,991; while British India sent 148,476 cwt., valued at £765,534. It is singular to notice that whereas in 1871 large imports of Coffee came to this country from Mauritius and the Cape of Good Hope, the supply fell to almost nothing in 1875, but whether owing to the failure of the crop through disease, or the discovery of other markets, or the introduction of a more profitable branch of culture, we are unable to say.

It may be interesting to some to learn that Coffee, as a beverage, was introduced into Arabia about the commencement of the fifteenth century, and soon superseded a drink previously prepared from the leaves of the Kât plant (*Catha edulis*). In Constantinople Coffee was first used about the middle of the following century, and in 1632 the first Coffee house was opened in London, and the popularity to which Coffee houses rose in after years is a well-known matter of history. B.

PANDANUSES, OR SCREW PINES.

AMONG the many ornamental-foliaged plants useful for general decorative purposes, the Screw Pines, or Pandanus, take high rank, being alike remarkable for their singular habit and the peculiar gracefulness of their foliage. When young, they form handsome objects for dinner-table decoration, associated with such *Dracenas* as *D. Cooperi*, or others having recurring leaves. One of the most useful for this purpose is *P. javanicus variegatus*, the foliage of which is beautifully striped with creamy-white bands that contrast well with the lustrous green running between them. What renders this particular kind of such value where glass accommodation is limited is that, unlike some others of more recent introduction, it may be kept long in a small state by simply confining the roots; but, when this is done, to keep it in health it must have abundant supplies of water, or the leaves soon assume a sickly hue and become infested with scale, an insect to which all the Pandanus are more or less subject. Although this variety admits of being restricted, it grows rapidly if well treated, and in two or three years may be got to the size of a large specimen for exhibition or conservatory embellishment, where, if previously hardened, it will stand well for two or three months during the height of the summer.

When required for either of these purposes, the best way is to give a good shift early in spring, and place it at the warm end of the stove, where it can obtain plenty of sun and light, in which position, once it gets hold of the fresh soil, its growth will be rapid. The leaves being of a gracefully pendulous nature, the plant should be elevated, in order that the tips may not touch the stage on which the plants stand, or suffer injury by being smothered up by others surrounding it. Raised on an inverted pot, this will not happen, and the base will become better furnished than it otherwise would be. *P. javanicus variegatus* is not, however, so difficult to manage in this respect as some of the others, owing to the free way in which it forms suckers, which, if not taken off, cluster closely around the bottom and make quite a thicket. These are the parts to get for propagation, and any of them taken off carefully with a heel without being bruised will strike, if plunged in strong bottom-heat. To prevent losing them from decay, the ragged end should be trimmed with a sharp knife and left a short time to dry before being inserted in sandy soil in 3-in. or 4-in. pots. If this be tolerably moist, they will not require water for a week or two, as the drier they are kept without flagging, the more likely will they be to root. Why many fail in striking Pandanus and plants of that class is in placing them where they get syringed, as, owing to the formation of the leaves, they are receptacles for water, which, unless the plants are turned upside down, stand in them till the tender parts are destroyed. To insure safety, therefore, they should be attended to in this way once or twice a week till roots are formed, after which, as growth progresses, they are not so susceptible of injury.

Another exceedingly ornamental Pandanus is *P. Veitchii*, a handsome kind, partaking somewhat of the character of the one already named, but it is of bolder habit, has broader leaves, and is well suited for occupying a vase in a prominent position. Where space can be

Coffee Shrub in Fruit.

clear them of mucilage and other useless matter. They are then dried and passed through another machine or mill, which removes their parchment-like coats. The berries are now in the Bean-like form so well known to us, and are dried well and packed in barrels for exportation. The roasting process enlarges the bulk of the bean, but it loses in weight to the extent of one-fifth or even more by the process, and its chemical nature is also essentially changed, since, by the action of heat, are developed the volatile oils and aroma to which the flavour is mostly due. On careful roasting its value as a beverage much depends, and this is the principal reason why the French and Italians—to say nothing of the Turks, who were the first to use the beverage in Europe—excel us in its preparation, since they are careful to roast their Coffee immediately before it is required for use, and so the perfection of flavour is obtained in all its pristine freshness. Freshly-ground Coffee is a great absorbent; indeed, in this way it forms one of the best of disinfectants; hence it will be evident that Coffee, after being roasted and ground for use, should be carefully preserved from contact with the air, or germs of disease may thus unwittingly be imbibed. Indeed, Coffee should neither be roasted

afforded it, *P. utilis* forms a grand-looking object, as it has leaves quite 2 in. wide, and from 3 ft. to 4 ft. long, which, with their red spines, have a striking effect. The twist or screw in the stem of this is very marked after a year or two's growth, the axils of the leaves being arranged in regular spiral whorls, as is also the case with most of the others. *P. elegantissima* is, as its specific name implies, a very elegant variety, the habit of which is dwarf and bushy, and the plant altogether one of the best adapted for use in rooms or windows during the summer.

One great advantage in growing any of these *Pandanus*es is that they are not, like the generality of stove plants, tender, requiring much care and good management to have them in proper condition, as, under anything like fair treatment, they always thrive and look well, and are available for use at any time during the year. The only thing to avoid when they are wanted for table decoration is not to let them stand about in cold places, or keep them out of heat, for, although more enduring than others that have soft, fleshy leaves, the roots get chilled, and when this takes place, the edges of the foliage are apt to become discoloured, which greatly detracts from their appearance. In order to keep them well furnished, it is a good plan when potting to drop the ball a little lower at each shift, as then it not only brings the foliage nearer the pot, but gives the plants a chance to root afresh round the collar, which they readily do.

*Pandanus*es will succeed in almost any soil if plenty of water be given, but that which brings out the variegation better than any other is such as is poor and that contains plenty of sand. This, with either peat or loam, suits them well, and allows the large roots to ramify freely. S. D.

DOUBLE-FLOWED IVY-LEAVED PELARGONIUMS GROWN FOR TRIAL AT CHISWICK.

By A. F. BARRON.

The introduction of M. Liebmann's double-flowered form of the Ivy-leaved Pelargonium, König Albert, some few years ago was a pleasant surprise, being the commencement of a new class of highly ornamental plants which are exceedingly suitable for the decoration of the conservatory and also for cut flowers. The elegant and chaste forms of the single-flowered varieties of the Ivy-leaved Pelargonium bear no comparison in point of appearance with the new double-flowered varieties for which we are mostly indebted to that very skilful hybridist, M. Lemoine, of Nancy. These new double-flowered varieties all belong to the true petatum or trailing species, and are of various shades of colour, from almost pure white to dark lilac.

The following received first-class certificates:—

A. F. BARRON (Lemoine).—Flowers large and very double, of a pale rose-lilac colour, with dark veins on the upper petals; produces a large truss. A very fine variety. Flowers of the largest and finest forms.

ELFRIDA (Ebert).—Flowers large; dark lilac, shaded with purple; of fine form. Trusses of medium size. Very free flowering. A pleasing lively-coloured variety.

LUCIE LEMOINE (Lemoine).—Flowers large; rather loose; of a very pale lilac colour, with dark veins on the upper petals. Free flowering.

MADMOISELLE ADRIENNE BARAT (Lemoine).—Flowers large and very double, pale lilac. Very free flowering and fine habit.

SARAH BERNHARDT (Lemoine).—Flowers almost white, the upper petals veined and tinged with lilac. Free flowering. Robust growth.

VISCOUNTESS CRANBROOK (Lemoine).—Flowers large and full, white, shaded with rose-lilac colour. A pretty variety. Free flowering.

Classification of Varieties according to Colour.

FLOWERS WHITE OR VERY PALE LILAC.—Lucie Lemoine, Madame Emilie Galle, Sarah Bernhardt, Renoncée, and Viscountess Cranbrook.

FLOWERS PALE LILAC.—A. F. Barron, La Fiancée, and Mademoiselle Adrienne Barat.

FLOWERS DARK LILAC.—Elfrida, Madame Perle, and König Albert.—"Royal Horticultural Society's Journal."

Begonia multiflora.—This is, without doubt, one of the best of *Begonias*, combining, as it does, in one plant all the good properties of both the flowering and fine-foliated section. In growth it is dwarf and compact; the foliage is very ornamental, and, even in the case of the smallest plants, from the axil of every leaf is produced a bunch of beautiful flowers nearly large enough to hide the leaves, and they remain in perfection for a very long period. For furnishing stands or baskets I do not know any plant to excel it.—J. GROOM, *Linton*.

Hoya bella in a Cool Vinery.—A correspondent in last week's GARDEN says (p. 311) that "*Hoya bella* can be grown only as a stove plant." This remark may prevent some from cultivating this very fragrant and beautiful plant. I have had specimens of it for several years in full perfection in a cool Vinery planted in peat, and sparingly watered through the winter.—H. A. H.

Rhynchospermum jasminoides Hardy in Devon.—I have had this planted out against a south-east wall, and even during the past severe winter, with the protection of only a single Laurel branch, it has stood quite uninjured by the frost, while on each side of it *Philadelphus mexicanus*, *Eccremocarpus scaber*, *Ceanothus punicus*, *Habrothamnus*, and even *Passiflora corallæa* were either killed or cut to the ground.—H. A. H., *South Devon*.

THE FRUIT GARDEN.

GOLDEN CHAMPION GRAPE NEAR BRISTOL.

In reply to "J. S. W.'s" remarks (p. 324) on this subject, allow me to state that I mentioned the Vine in question because the Grapes produced on it are well known to be unusually excellent. I may also add that Bristol and its neighbourhood this winter have been little different, as regards the severity of the frost, from the greater portion of the kingdom; therefore what holds good in practice in the one place will hold good in others under like conditions. The Vine just named was started in January, and was just approaching the flowering stage at the time which I mentioned. At the time when it was started the soil was at its lowest temperature, and if it were necessary to have an equal root and top temperature for Vines started in November, it is also the same if started in January, or even later. "J. S. W." cannot escape the logical consequences of his line of argument in this direction. I have had to do with a good many Vines in my time, and have seen a good many more, but it is news to hear, as "J. S. W." states, that Vines advanced so far as this in the middle of March will only ripen their fruit in time for the autumn shows. But in discussing this subject, "J. S. W." occasionally makes admissions that seriously damage the views which he strives to establish; he refers to his Vines in a bleak district of Yorkshire, that without a particle of protection on the border were on the 5th of April showing magnificent shoots and bunches. Now these Vines must have been started in the beginning of March, or earlier; up to March we scarcely had a glimpse of sun, and at the end of February, by testing the earth's temperature, I found that it had not risen perceptibly; and again, on the 16th of March it was only 4° higher than in January. "J. S. W.'s" Vines are about as strong evidence against all he has written on the subject as could well be adduced. He speaks of examples of cold roots and warm tops being few and ill to find. If he had occasion to move about the country as much as I have, he would see plenty. Not more than three miles from where I now write I could show him a couple of instances, both cases in which the produce is sold in Covent Garden Market. In one the crop is fast colouring, and will be all sold by the middle of May. The Vines are Black Hamburgs and Buckland Sweetwater planted in the usual way just inside the front wall, with all their roots outside, and not a vestige of anything has there been over them except about 6 in. of litter on some 6 ft. of space up to the front wall. In the other place the crop is about stoning, with the roots in a like position, but not in any way more protected; and this is how they are treated year after year, as I can testify, and the soil is as heavy, cold, and retentive as it well could be. The growers are men who have for a quarter of a century been engaged in Grape forcing, with the strongest of all incentives—competition in the market—to treat their Vines in a way in which they will produce the most money; and in this they are successful, as no better early Grapes reach Covent Garden.

I have a letter before me from a friend in the north of Yorkshire who regularly begins to cut Grapes early in May. He writes: "I have the best crop this year that I ever had, although I was not in a position to obtain protecting material until most of the summer warmth had escaped from the soil, and then I had only a thin covering to throw off the rain and snow-water. Some 2½ ft. of snow have fallen altogether during the winter." The severe winter we have passed through has been unfortunate for "J. S. W.'s" ideas about the necessity for warming the roots of forced Vines, as, from what has come within my own knowledge, the discussion that has taken place on the subject has induced many who have hitherto followed the practice to test its value by dispensing with all but protection; and they are so far satisfied with the results that the fermenting heap with them will henceforth be a thing of the past.

T. BAINES.

GLANDS IN PEACH LEAVES.

To the naked eye these look like mere warty excrescences on the stem and base of the leaf; but that they are there for some useful purpose there can be no doubt; my own opinion is that they serve as reservoirs of food for the leaves, and that this is the case is proved by the fact that glandless-leaved varieties are, as a rule, very subject to

Fig. 1.

mildew; for instance, the following glandless kinds, viz., Royal George, Early York, Noblesse, Early Newington, and Sulhamstead, are all notoriously subject to attacks of mildew. There are three types of foliage in the Peach, as will be seen by reference to the

Fig. 2.

Fig. 3.

annexed illustrations:—Fig. 1 is glandless, fig. 2 shows kidney-shaped glands, and fig. 3 round glands. Of course, it is not claimed for the two latter types that they are entirely exempt from liability to the attacks of mildew, but their liability to it is not great in comparison with glandless kinds. W. W.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Naming Fruit Trees.—This is a subject that has been, and still is, very much neglected, but that such should be the case is to be regretted when we consider how much more interesting and convenient it is to have correct names for all our fruits. As Peaches and Nectarines are oftener found grown and exhibited under wrong names than most other fruits, a few words in reference to these, while the trees are in bloom, may not be out of place. It frequently happens that when one enters a new situation no names are found attached to any of the fruit trees, and to get their correct names is no easy task. I have frequently had, even from nurseries, Noblesse for Royal George, *Violette Hâtive* for Noblesse, and so on; but, with the help of books, I have generally managed to put things straight. Now, as I have said, is the time to take the matter in hand. In the first place, carefully note down the size, shape, and colour of the bloom, then in a few weeks, when the leaves are fully developed, note down the size and shape of the leaf, whether glandless or if with glands, whether the latter be round or kidney-shaped; then, when the fruit is ripe, note the size, shape, and colour of that and the exact date of ripening. One more item remains, and that is, to know whether the fruit is a freestone or a clingstone, and the size and shape of the stone. All these things being carefully noted by the aid of the "Fruit Manual," or Scott's "Orchardist," I dare ven-

ture to say that the correct name of the fruit in nine cases out of ten will be ascertained. The names of Apples, Pears, and all other fruits may also be discovered by careful observation in the same way. —H. HARRIS, *Denne Park*.

Grape Culture in Market Gardens.—"J. S. W." (p. 325) furnishes some interesting remarks regarding rapid returns from young Vines; no one would question the capability of young rods in vigorous health to finish off a good crop the second season of their existence. But the statement that good crops have been produced the first season, or in nine or ten months from the time when the eyes were inserted, is certainly something new in Grape culture. "J. S. W." says this feat is not likely to be surpassed, but if it has been accomplished once, there is no reason why it should not become, at least, an established practice. I have myself been satisfied if I could get well-ripened canes in one season's growth, and fruit early the next or within 15 months from the time when the eyes were inserted. The Vine requires a certain period for active growth, and, accommodating as it is in regard to rest, it must, nevertheless, have a period of rest before it is actively started for producing a crop. Therefore, I think "J. S. W." should give us a detailed account of how a crop of Grapes may be harvested from Vines raised from single eyes in nine or ten months. —J. GROOM, *Linton*.

Pruning Apples and Pears.—Having grown on for several years from what is called the maiden state a number of Apple and Pear trees in the pyramid form, and adopted, year after year, the common practice of shortening back the previous summer's growth, I have at length found that this form of pruning after the first few years becomes a mistake, and simply leads to the production of wood and no fruit. The tree is so much employed in making good the amputations of the preceding winter, that it is unable to perform the work of producing fruit-bearing buds, and thus every season's growth simply results in waste. Having abandoned the cutting-back practice altogether last autumn, and contented myself with the taking out of all superfluous growth, I now find in looking over the trees that in large numbers of them almost the only fruit-buds are at the extremities of the very wood that, under the hard-pruning practice, would have been cut away. Here begins the first prospect of fruit, and once the energies of the trees are directed into that channel, instead of the production of rank, barren growth, crops from year to year will be assured. There is one valuable feature in this habit of fruiting at the extremity of the previous season's growth, and that is, the weight of the fruit causes the shoots to bend downwards, and thus the rapid upward passage of the sap being checked, the dormant buds are plumped and forced into the position of fruit spurs. Beyond a little judicious thinning the best annual pruner of either an Apple or Pear tree is the production of a good crop of fruit. —A. D.

Fruit Culture for Market.—"F. W. B." (p. 310) quotes some very tempting averages of profit from fruit orchards in different localities, and, doubtless, they are realised sometimes, or fruit growers could not exist; but for the established orchards a high rent is demanded, and the expense of planting orchards and cultivating them up to a bearing period are weighty matters. With owners of land it is quite another matter, and "F. W. B.'s" suggestion that landlords should plant orchards is an excellent one, as the uncertainty of recompense for improvements is greatly against tenants planting largely, for few stop long enough in one holding to reap the full benefits arising from their plantations. Co-operative fruit stores are much wanted, in order to enable consumers to get the benefit of abundant crops. If some such ready means of placing consumers in direct communication with the growers were in existence we should hear no more of quantities of valuable fruit being spoilt through being unremunerative. At present the culture of fruit for preserving is about the safest investment, and promises to become a large industry in this neighbourhood, the fruit being sold direct to the manufacturers. —J. GROOM, *Linton, Kent*.

Apple Culture for Market in Scotland.—In Scotland the cultivation of Apples for market purposes is not carried on now to any extent worth naming, although at one time the Apple crop was one of considerable importance, especially in the Carse of Gowrie and the Vale of the Clyde. The leading kinds were Allankbank Seedling, Cambsanethan Pippin, Keswick Codlin, Early Julian, Ecklinville Seedling, Fulwood, Tower of Glamis, Golden Noble, Hawthornden, Red Juneating, Grey Leadington, Oslin, Old Pearmain, and Yorkshire Greening; these were the leading kinds. In more recent times growers planted such as Lord Suffield, Cox's Orange Pippin, Blenheim Pippin, and Warner's King; but, as has just been stated, not to any great extent, many failures having turned market gardeners against their cultivation. A crop of Apples is quite an exception in Scotland. —DAVID SYME.

Strawberries for Table Decoration.—Strawberries, as a rule, are grown to eat, but there is no reason why they should not

gratify the eye as well as the palate,"and, in fact, at this season of the year, I prefer the sight of a Strawberry house full of fruit in various stages of development to all other sights in a garden. For dinner-table decoration a centre-piece or two side groups, consisting of about half-a-dozen pots of ripe Strawberries bedded in Moss, is, according to my idea, perfection, the foliage being so ornamental, and the glistening fruit under strong light so tempting. Any one who has only had Strawberries handed round, should try how much better they are when gathered from the growing plants on the table.—J. GROOM, *Linton*.

Destroying Red Spider on Strawberry Plants.—Allow me to correct an error (p. 275). It should be 1 oz. instead of 4 oz. of soft soap to 1 gallon of water.—J. C.

TREES, SHRUBS, AND WOODLANDS.

CITY TREES.

TOWARDS the close of last autumn, being desirous of ascertaining the best kind of trees for planting in the City of London proper as distinguished from its suburbs, I made several excursions through the territories of the Lord Mayor and Corporation, from Barbican on the north to the river on the south, and from Staple's Inn on the west to Tower Hill on the east. Although many capital cities of Europe can boast of longer and more numerous open spaces filled with greenery than the city of London, there are few that possess so fine a growth of individual trees as we do in the very centre of our own close, smoky, foggy business quarter. Leigh Hunt tells us in his "Town," "that there is scarcely a street in the city of London from some part of which the passenger may not discern a tree;" a dictum which is perfectly true, as far as the principal streets of the metropolis are concerned. I know of no capital city, with the exception of Constantinople, that can match that splendid specimen of tree growth, the venerable Plane, in Stationers' Hall Court, which, although literally immersed in a square cell of brickwork, seems to thrive as bravely as if it were growing in its own native woods. The hot and dusty wayfarer, during the early summer, who seeks a refuge in this court from the bustle and clatter of Ludgate Hill, and pauses awhile beneath its green canopy, every twig of which forms a perch for a twittering sparrow, may shut his eyes and fancy himself for the nonce in some primeval forest, instead of in the heart of the City of London.

Beginning our excursion at the north-west corner of the City boundary, the first oasis that we come to is the garden of the chapel belonging to Staple's Inn, which lies behind the fourteenth-century houses in Holborn, immediately opposite Gray's Inn Lane. It is better, however, to enter it from Southampton Buildings. I have frequently astonished friends of mine who have lived all their lives in London by taking them through Southampton Buildings and Staple's Inn, even old inhabitants of the locality being unaware of the existence of this green spot. The garden is fairly well laid out with a maximum of turf and a minimum of flower-bed; but its principal beauties lie in its Planes, Figs, Vines, and Virginian Creeper. Passing along Holborn in the direction of the Viaduct we speedily reach the churchyard of St. Andrew's, Holborn, the Planes and Poplars of which are its chief excellences. There are a few Hawthorn bushes, but no matter how beautiful they may be when laden with fragrant blossoms, they wear a very shabby, ragged, withered appearance towards the end of the season. At St. Sepulchre's, on the other side of the way, there are some excellent Planes, but the Lime trees were in all their autumn ugliness long before the middle of September. In the central garden in Smithfield the Thorns and Poplars bid fair to thrive, and in years to come the Planes will no doubt do their best to rival their splendid brethren in the courtyard of St. Bartholomew's Hospital hard by.

Charterhouse Square is another well planted open space—a double row of Planes stretching diagonally from corner to corner of the enclosure in the form of a St. Andrew's cross. There are also a few Thorns, Elms, Limes, and a Sycamore or two, all of which were a very rusty appearance. A few Ashes and Poplars seemed to have borne the summer's heat with great patience, especially the latter. At one of the houses in the square there is a fine Grape Vine, which was green and beautiful, a remark that will apply to a splendid Fig tree on the other side of the enclosure. In the churchyard of St. Olave, in Silver Street, there are some fine Planes and Poplars, although it is inconceivable how they flourish so well in such a close locality.

Finsbury Square made a fine show with its Poplars and Planes, the Elms, Thorns, and Ashes coming off second best. Finsbury Circus, though smaller than the Square, is much better laid out, and beats its neighbour out of the field in the way of variety. The

Sumach and Ailantus were in great beauty here in the middle of October, and the Robinias and Figs were as green as they were in the preceding May. The Lilacs and Laburnums here, as everywhere else, wore a most pitiful appearance.

Those who are not acquainted with the locality will be surprised to find some fine Figs and Thorns in Draper's Gardens, a newly-made street built on the site of Draper's Hall, on the south of London Wall. On the north side of London Wall there is a row of leggy-looking Limes, whose condition was such as to convince any disinterested observer of the futility of trying to grow this tree in the smoke and foul air of the City of London. This remark applies with even greater force to the Laburnum and Lilac. At the beginning of October the withered condition of these Lime trees was made all the more ghastly on account of a few of them having put forth a second growth of pale, sickly-looking leaves.

In the newly-laid-out churchyard of St. Botolph, Bishopsgate, we had Planes, Poplars, and Privets all in excellent condition, the latter especially, which, with great good taste, had been allowed to grow in their own way, instead of being pruned into ugliness. In the disused churchyard of St. Martin's Outwich, in Camomile Street, Bishopsgate, there are two fine old Planes in fair condition, considering they are planted close up against the wall of a house.

Wandering down Houndsditch we come to Aldgate Church which possesses a fine row of Poplars. There are some splendid Ashes, Planes, Sumachs, and Robinias on Tower Hill; but these are beyond the City boundaries, and it is only of City trees that I wish to speak.

There are numerous other green spots in the City which I visited, such as Lawrence Pountney Hill; Queen Street, Cheapside; Wood Street, Cheapside; St. Magnus' Churchyard; Fish Street Hill; St. Swithin's Lane, &c., but they all taught the same lesson, and that is, by properly selecting new subjects and rejecting old ones, the few open spaces in the City may be made green and lovely, if not for ourselves, at least for our children and grandchildren. I may remark, *en passant*, that I have purposely excluded the Temple Gardens from my list, although they are within the boundaries of the City, for the all-sufficient reason that from their extent and openness they can hardly be allowed to come within the same category as such confined spaces as Finsbury Circus and Charterhouse Square.

The splendid specimens of the Western Plane to be found within the City boundaries prove most conclusively that it is the city tree *par excellence*. Smoke, dust, drought, foul air, do not seem to have any effect upon it. Of its beauty and hardiness there is no need to speak, for fine specimens are so common throughout the country, that it would be waste of time and space to enlarge upon its numerous points, further than to say that it possesses every property that best befits a city tree.

If the Plane is the Emperor, the Robinia is unquestionably the Crown Prince of city trees. It has not the majestic beauty of its superior, either in leafage or branchage, but it is fully fitted in every other way for city planting. In the autumn of 1875 I travelled from the shores of the Black Sea to those of the Atlantic, passing through Constantinople, Athens, Messina, Palermo, the principal cities of the Italian Continent, Macon, Dijon, Lyons, Orleans, Rennes, St. Brienc, and across the sea to Jersey. The summer had been an exceptionally hot one, and in the south of Europe the whole of the ordinary vegetation was burnt up; but, wherever I went, I found the Robinia still in the prime of its verdant loveliness. In the King's garden at Athens, in the garden of the Villa Nazionale at Naples, in La Flora at Palermo, where even the Orange trees, Date Palms, and Pepper trees seemed to be suffering from the heat and drought, the Robinias were refreshing masses of emerald verdure. There are comparatively few specimens of the Robinia to be found in the City of London, and, where they do occur, I am sorry to say that their natural beauty has been only too often interfered with by the ruthless hand of the pruner. There is no excuse for this, for the different species of Robinia are equal to providing the most capricious planter with subjects of almost every form that he can desire, from the bushy to the pendulous, without being obliged to resort to mutilation. This was the tree that William Cobbett extolled so much as a timber producer. Its value as an ornament in city and town gardens can hardly be overestimated, although its wood, in this country, at any rate, has never been satisfactorily used for industrial purposes.

Another tree, which is invaluable for city planting is the Ailantus glandulosa, whose large, long, half pendulous pinnate leaves contrast finely with the foliage of the Plane and the Robinia. Last autumn, in Finsbury Circus and other parts of the City, it remained green and fresh when many of its neighbours were already dropping their leafy garments. It seems to suffer from smoke and foul air almost as little as the Plane and the Robinia. It is to be regretted that it has been so sparingly used in the City. I could name a dozen spots where it would form a most agreeable contrast to the trees already planted. Finsbury Circus seems to be the only place where its true value has been appreciated.

The common Fig is another tree which seems to thrive everywhere alike in confined localities, such as Staple's Inn and Laurence Pountney Hill, as well as such open, well-ventilated spaces as Lincoln's Inn Fields and Bloomsbury Square. Its broad green leaves and bushy form give it a high value as an ornament when mixed with trees of contrasted habits. There are some excellent specimens scattered about the City, but they might be largely increased with advantage.

Poplars, more especially the large-leaved sorts, seem to be perfectly at home in the smoke, as those in St. Andrew's and Aldgate Churchyards abundantly prove. The fastigate varieties do not seem so well fitted for city work. The Vine, too, grown as an ornamental plant, be it understood, seems to be a most valuable addition to our City greenery, judging by the specimens in Staple's Inn, Charterhouse Square, and elsewhere. Its value for this purpose will be apparent to every one who has allowed a Vine to run wild without a thought of the Grapes it would yield. Its congener, the Virginia Creeper, is also always a success wherever it may be grown.

The Stag-horn Sumach and many of the Ashes are also good trees, and the Catalpa, the Mulberry, the Paulownia, and the Tulip tree would, I have but little doubt, grow just as well. The Paulownia, from its comparatively low and bushy habit, ought, when combined with the Plane or the Robinia, to form an excellent subject for street planting. The Victoria Embankment, Northumberland Avenue, and Abbey Road, St. John's Wood, have all been planted with Planes and nothing else. It seems a pity that some attempt at variety was not made at the first going off. The Plane is undoubtedly the best of all city trees, but there is no reason why it should not have a foil now and then in the shape of a Robinia or Paulownia. In the City, and, indeed, in most of our town plantations, trees of a weeping habit, such as the Weeping Birch, the Weeping Willow, the Weeping Ash, the Weeping Elm, the Sophora, are almost entirely neglected. In the triangular enclosure in the middle of Harrington Square, Hampstead Road, there is a Weeping Willow, which, by its contrast with the more erect trees near it, is a most artistic feature in the picture. Although a high authority on the subject has given it as his decision that dark-leaved Oaks and Beeches are inadmissible in a tree picture, I must venture to differ from him. Surely dark foliage, when used sparingly amongst masses of green, cannot fail to satisfy the artistic eye.

It is time, however, to speak of those trees which should be resolutely banished from our City enclosures. The first of these is the Lime. It is true that in the early summer the Lime, with its black trunk, bright green leaves, and white tassels of sweet-smelling flowers, is an admirable object, but in the course of a very few weeks we have to pay a heavy penalty for our pleasure. The leaves begin to shrivel in the sun, the trees are invaded by legions of caterpillars, and the Lime is no longer a beautiful, but a painfully ugly object, which only becomes tolerable when the winter winds have whisked off its last ragged leaf. The same remarks apply, though perhaps in a secondary degree, to the Lilac and Laburnum. Lovely as these well-known trees are in the beginning of the season, nothing can equal their raggedness later on. Could Limes, Lilacs, and Laburnums be bedded out in the spring, and taken away when they begin to show signs of rustiness, there would be nothing to say against them; but, as we have not yet reached such a pitch of civilisation, we must either be content to put up with their latter-day shabbiness, or else remove them altogether. Judging from the general condition of Elms, Horse Chestnuts, Hawthorns, and Sycamores scattered so sparingly about the City, they seem to thrive but poorly, although their failure is hardly so complete as the trees just mentioned. The Horse Chestnut especially seems little fitted for city use, although it grows fairly well in Regent's Park. As this article is intended to treat of trees and shrubs grown for the sake of their foliage, I shall say nothing about supplying the places of such subjects as the Horse Chestnut, the Thorn, the Lilac, and Laburnum. With such a list as the above city planters might, in a few years, make our open City spaces perfect little Paradises of leaf and branch beauty at a very small outlay.

A word about the lesser vegetation in our City squares. Like his suburban brother, the City gardener seems to be hopelessly possessed with the idea that the only underwood fit to grow in town must necessarily be either the everlasting Laurel, the perpetual berryless Aucuba, or the eternal well-cropped Privet. The sooner the whole tribe of so-called evergreens is rooted up the better, and if our English Privet followed them it would be no great loss, for at best it is a weak-looking shrub. London gardeners who cannot keep their hands from mutilating the Privet should visit the hedges of it in the Regent's Park, where, for a wonder, it is allowed to have its own way, and therefore speedily grows into a refreshing screen of verdure. But, pretty as it is, it is distanced by its Japanese congener, which has larger and glossier leaves, and is altogether more sturdy in habit. Sometimes a gardener, bolder than the rest, plants

a few Rhododendrons, Euonymuses, or Hollies. In the first instance the result is generally a dismal failure; in the two latter a gratifying success, as the specimens in Finsbury Square and elsewhere abundantly prove. There are hundreds of hardy shrubs, beginning, let us say, with the Box and the Berberry, that I feel confident would grow like weeds in the most confined city enclosure. This part of the subject, however, I do not wish to treat of further, as, during my investigations, I confined my attention almost entirely to trees.

CHARLES W. QUIN.

AUCUBA BERRIES.

WITH regard to these, I dare say both "J. G." and Mr. Tillett are right, though the success attending their respective efforts is so widely different. If about this season we carefully examine a batch of seedling Aucubas, we will find that the time occupied by the whole batch in flowering is about six weeks; some early, others late. The originally imported variegated Aucuba (now so extensively cultivated) is a female, and one of the latest to flower in spring, so that berries being the desideratum, it would serve no purpose to plant alongside of the old Aucuba one or more plants of the earlier flowering males. "J. G.," who has been successful in putting berries on his plants, must have had male plants which blossomed with his females. Mr. Tillett's non-success (and his is by no means exceptional) was probably due either to his plants flowering at different times, or to the flowers of one or other sex, or both, being injured (a common occurrence) by frost or cutting winds. For the latter reason, we may always expect to have better crops of Aucuba berries in the warmer parts of Great Britain than in other less favoured localities.

In the foregoing, many, I have no doubt, will find satisfactory reason for the success or non-success attending their efforts to put berries on their Aucubas, and here I probably ought to stop; but, having just lately looked with admiration on a large plant literally bent down with the weight of its large, red-tinted fruit (not fully coloured yet), you will, perhaps, indulge me with space for a few more remarks on this excellent evergreen shrub. We have seen that many of the seedlings do not flower at the time when the common kind does; and, to further the certainty of putting berries on it in the future, it is obvious that nurserymen have a duty to perform, not only for their own credit and benefit, but in justice to their patrons, and that is, the selecting (for sale) from amongst the thousands of seedlings now raised by them such male plants, be they green or variegated, as flower at the time when the old female plant blossoms. Many of each batch of seedlings are green, and the sexes seem to be fairly proportionate. Numbers of the variegated seedlings are better marked than the popular kind, and some of them may, some day, supersede it. It is scarcely possible to speak too highly of the green seedlings, there being few, large-leaved evergreen shrubs that rank superior to them, and the wonder is that they do not often find places in the forecourts of our cities than they do, seeing that so many naturally handsome and elegant shrubs are so denuded of the beauty natural to them as to become unsightly skeletons.

GEORGE SYME.

BORRORASH.

— Mr. Tillett asks if his experience in reference to the fertilisation of Aucuba plants is exceptional? I think it is, as Aucubas often get fertilised, even when the male and female plants are at great distances apart, and when one would think it would be impossible for the pollen to reach the female. Accompanying this is a branch of the variety which we call *A. himalaica*, which was confined in a corner in an old Vinery all last year, and, to my certain knowledge, no male Aucuba was nearer it than 200 yards, yet this plant was loaded with berries, and is certainly one of the finest berry-bearing Aucubas which we have, its large scarlet fruit remaining on the plant for many months together. I planted a few males amongst my bed of the common Aucuba, and the result was that every plant became fertilised and bore berries. I enclose also a sprig of what we call *A. latifolia*, a green kind, which, it will be seen, is a little later in flowering than the female kind, but this is owing to the latter having been kept in the house all the winter.— J. SCOTT, *Merriott*. [The specimens sent by Mr. Scott were covered with berries, most of which measured $\frac{3}{4}$ in. in length. He also furnished leaves of what he calls Scott's Aucuba *japonica macrophylla*, a finely variegated variety, and strikingly handsome. One leaf of it which we measured was just 1 ft. in length and 5 in. wide at the broadest part, and in appearance seemed more like the leaf of a great Arum than that of a shrub.]

— Mr. Tillett's difficulty in getting the flowers of his female Aucubas fertilised with so many male plants growing amidst them is surely exceptional, as I have so far seen little difficulty in getting

berries in abundance where male plants were near. An excellent plan, and one which I have seen adopted with success is, where the male plants are precocious to grow them in large pots, and keep them in the cool shade of a north wall until the female plants are in bloom, then carry these pot plants to the required place, and elevate them just above the tops of the female plants; the wind will then more freely distribute the pollen over the blooms to be fertilised.—A. D.

—Mr. Tillett's Aucubas will doubtless in time produce fruit. It is not an exceptional circumstance for the males in certain plants to flower before the females; that happens in the Hazel, yet we all know that Nuts come without artificial fertilisation. In the case of the Aucuba, we have many bushes quite laden with beautiful red berries, though the male varieties are at great distances off. If Mr. Tillett's plants have only been planted out one or two seasons, I would recommend him to allow them to remain undisturbed, and await the result. Although I have grown Aucubas largely for several seasons, I never saw them so well berried without artificial fertilisation as they are this year.—JAMES GROOM, *Linton, Maidstone*.

—Mr. Tillett's experience as to the male Aucuba blooming before the female is not exceptional, at least I experienced the same difficulty; but, fortunately, I had the males in large pots and plunged them under a north wall, where their progress was retarded, and when the females were in flower, or nearly so, the males were planted amongst them. The result is, that at present every female has red berries on it, though, by some means, the quantity has been reduced during the winter. I may add that this year the blooms of both males and females appear, as far as I can see at present, to be more uniformly developed.—J. WOOD, *Woodville, Kirkstall*.

—I would recommend Mr. Tillett to take up a few of his male plants, pot them in large pots or boxes, and place them in some cool, shaded situation until his female plants are in bloom, and then place his males among them. In this way I have succeeded in getting a good crop of berries.—D. P., *Hayward Heath*.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Hardiness of the Camellia.—As one amongst the many instances of the hardy constitution of the Camellia I observed at Kew the other day in an open border about half-a-dozen good-sized plants, which, during the last and previous winters, have been quite unprotected, expanding flower buds in abundance, though large numbers have fallen. One variety in particular is very attractive, being in full flower with its blossoms scarcely inferior to those grown under glass, and the foliage is of a deep glossy green.—W. G.

—Many predicted that Camellia blooms on open-air bushes would fall off after the late severe winter, but I find that such is not the case; here Camellias are now flowering profusely, even the double white being loaded with blossoms. Up to the present time we have scarcely had two fine days together free from frost or snow or driving storms; still the blossoms keep expanding, and some large bushes which we recently transferred to the conservatory have, in spite of removal and cheek attending it, unfolded a glorious display of bloom. As to hardness, I can safely assert that the Camellia is harder than the Laurustinus, which with us is much browned. I may also add that plants of the old white Azalea planted out in the open air are quite healthy, and swelling their buds up for flowering.—J. G., *Linton Park, Maidstone*.

Conifers and the Frost.—Amongst the numerous varieties of Conifers growing here very few have suffered from frost during the past severe winter. *Arancaria Cunninghamii* does not appear to be injured in the least, but it is well sheltered on all sides by loftier Conifers, and several other tender varieties have thus far escaped, while many of our ordinarily hardy flowers have been killed, and the bloom of even the hardy *Forget-me-not* has not been all cut off. I may add that a small specimen of *Libocedrus Doniana* is very much injured by the late spring frosts, the outer shoots being all browned, but otherwise it is fresh enough. It is not, however, advisable to plant subjects that are not frost proof, as, except for their rarity, they are not more valuable than those that have been thoroughly tested as regards hardness.—J. GROOM, *Linton*.

Large Hardy Azaleas.—Mr. Osborn gives (p. 318) the measurement of some specimens of these which are growing in his nursery at Fulham. Allow me to give you the measurement of two specimens of the common *A. pontica* which are growing on the lawn here; one measures 10 ft. 8 in. in height and 26 ft. in diameter, and the other 9 ft. 3 in. in height and 19 ft. 6 in. in diameter. It is needless to add that such specimens when in flower are a sight worth travelling miles to see, and also when the leaves begin to ripen in the autumn. I can obtain no information about their age. They are growing in a brown, hazely loam and are in perfect health, and, as a rule, flower magnificently.—JAS. FAIRWEATHER, *Halston*.

PLATE CLXXVII.

A GROUP OF NEW TUBEROUS-ROOTED BEGONIAS.

Drawn by CONSTANCE FIERREPONT.

FEW plants have responded more readily to the manipulations of the hybridist than tuberous-rooted Begonias. *B. boliviensis* and *B. Veitchi* are species, and a very large proportion of the popularly-named varieties are the result of crossing these two sorts. If any particular species be crossed with another allied species the produce is generally intermediate between the two, and, therefore, amongst the first seedlings from the cross there are usually but few that prove to be distinct. In the next generation the variations are greater, and the further the seedlings are removed from the first cross the more frequently do these occur. Tuberous Begonias are, as has just been stated, a class of plants that are easily hybridised; seed-pods are speedily formed, and good flowering plants are produced in six or eight months from the time when the seeds are sown. Propagating them by means of seeds is effected by preparing well-drained 5-in. or 6-in. pots. Over the drainage place some Moss or fibrous loam, and fill up with a compost of two parts loam, one of leaf-mould, and a little sharp silver sand. The seeds will be found to be very small, and should only just be covered with the soil, which may be kept moist by placing a square piece of glass over the pot. January is a good month in which to sow the seeds, which will vegetate freely in a temperature of from 55° to 60°, and most speedily on a gentle bottom heat. The plants, when up and of sufficient size, should be pricked off into the same sort of soil as that in which they have been growing. When the weather is warm they may be placed in a greenhouse or cold pit, and be shifted into larger pots as they require more root-room. They will flower about midsummer beautifully in pots 5 in., 6 in., and 7 in. in diameter, according to the strength of the plants. A good compost for them to flower in may consist of turfy loam three parts, rotten manure one part, and one part leaf-mould and a little sand, to which may be added a few bits of charcoal to keep the compost open and sweet.

Many of the choicest varieties cannot be freely propagated, and, as a consequence, are high-priced. Those who want a good stock of plants to furnish their greenhouses or flower borders at a cheap rate would do well to purchase a packet or two of the best seeds, and treat them as directed above. A collection of the best sorts, if bought in the form of plants, costs a considerable sum, and they are only necessary for those who intend to exhibit them. Named varieties are propagated by means of eyes, with a leaf and part of the stem attached, and although every one of such eyes will produce roots, top growth, and also tubers, very few of them will make permanent plants, that is, they will not start or grow from the tuber the following season. It is only the few eyes that have what growers term a wood bud that are propagated, and these are usually found near the base of the stem. Some of the English-raised hybrids have very few eyes that will produce plants, and President Burelle, a fine double variety, is so difficult to increase, that its raiser, Mons. Lemoine, has, as yet, but a small stock of it.

Last year I saw in the nurseries of Messrs. Laing & Co., Forest Hill, over 150 distinct varieties of these tuberous-rooted Begonias in pots. They were arranged in one house and comprised nearly all the sorts that are worthy of culture. Amongst them were *W. E. Gumbleton*, rich scarlet, with the petals well shaped; *Charles Ballet*, crimson-scarlet, shaded with purple towards the centre; *Professor Pynaert*, a bright rose, large-flowered sort; *Bayard*, glowing scarlet; *Baron Hruby*, crimson, suffused with violet at the base, one of the best; *Vesuvius*, a very free-flowering orange-red; *Acme*, rosy-red; *Baron Léon Leguay*, pale rose, distinct and good; *Laurent Descours*, bright rose, and large and showy; *Alexander Leguin*, pale orange red; *Lecoainte*, a very beautiful variety with bright rose-coloured flowers; *President Burelle* and *Louis Van Houtte*, the two last double-flowered kinds. Besides these there were many seedling varieties flowering for the first time, which will, when sufficient stock can be obtained, take their place as standard varieties.

Tuberous Begonias have been grown in beds and borders very successfully. Last year single specimens might have been seen, out-of-doors 3 ft. in diameter and more than 3 ft. high, well furnished with flowers and foliage. As bedding plants in masses they are too brightly coloured for some tastes, but that will easily be toned down when the yellow and white varieties are sufficiently numerous to be used for outdoor decoration. J. DOUGLAS.

[For the varieties represented in the accompanying plate we are indebted to Messrs. Laing & Co., of Forest Hill. The large centre bloom is *Marquis of Salisbury*, that immediately above it *Mrs. Carter*, that below it *Thomas Bell*; the delicate pink variety is *Garland*, the yellow *Mrs. Colonel Long*, and that just below it *Rosy Box*.]

A GROUP OF NEW BEGONIAS. (LAINC).

GARDENING FOR THE WEEK.

Flower Garden.

Fortunately, in gardening, as in all other matters, there are counterbalancing circumstances which have this season been of the greatest service to us. The protracted winter having hindered planting and other extra work, such labours have now been accomplished during the time which in ordinary seasons would have been given up to mowing, but which this season did not require attention till at least three weeks past the usual time. A commencement, however, has now been made, and frequent cutting from this time to the end of September is indispensable, if a good turf be desired; and without this even the best of gardens becomes unattractive, which need not be the case, seeing that the expense of mowing is reduced to a minimum by the introduction of so many good kinds of lawn mowers. For the next two months the whole of the turf will require to be mown once each week, and after that once a fortnight to the end of the season. Walks should always be rolled after heavy rains, and the weeds on them be kept down by hand picking. It is not yet too late to turn and surface-gravel any that require that attention, but the sooner it is done, whilst the weather is showery, the better will they consolidate. Bedding out will now demand a large share of attention, both as to preparation of beds and plants. The system has grown to such proportions that for this, in many establishments, other most important and more profitable work has to be neglected; but so long as employers demand it, as many of them do, so long must we endeavour to make the best of a bad bargain. One way out of the difficulty is to make use of all the hardy plants that are in any way suitable for association with the general stock of summer bedding plants. We are certainly drifting in that direction, as note the use now made of Sedums, Saxifrages, Yuccas, Euponymuses, Retinosporas, and other small-growing shrubs, many of which are not only as effective as the best kinds of bedding plants, but far more so, at once adding additional grace to the parterre and neutralising that gaudiness which is now-a-days far too prevalent in nearly all summer bedding arrangements; moreover, such hardy plants can be left in position when the others are gone, and thus, in a measure, one great objection to summer bedding, viz., its transitory character, is obviated. There are other plants of a graceful nature which, though not quite hardy, are nearly so, and of the easiest culture, and well adapted for summer planting out, either as central objects in formal arrangements, or as "dot" plants to relieve the monotonous glare, which is unavoidable when Pelargoniums, Calceolarias, Lobelias, and similar plants are used. Among such are the following: *Acacia lophantha*, *Aralia Sieboldi*, *Grevillea robusta*, *Dracena australis*, *Chamerops excelsa* (small plants), *Ficus elastica*, *Araucaria excelsa*, *Phormium tenax variegatum*, *Solanum marginatum*, *Ferula gigantea*, and others of a similar character. Pansies, Violas, Calceolarias, Verbenas, and plants of like hardiness can now with safety be planted out, and the space they have occupied in pits or frames will be available for more tender subjects, such as *Iresines*, *Coleuses*, and variegated *Pelargoniums*. None of the plants should be allowed to get stunted through want of root space or drawn from want of head room; to prevent this either pot off or plant out in frames any that are likely so to suffer ere bedding time arrives. *Iresines* and *Coleus*, which are generally used in quantity, do best planted out in a warm pit, and such quantities of pots and boxes are set at liberty for other plants. Seedling *Lobelias*, *Centaurea candidissima*, *Cineraria maritima*, and *Perilla nankinensis* will all thrive well if pricked out in cold pits, and as to *Pyrethrum Golden Feather*, that with us never has any preparation other than sowing it in the warmest available position in the open air; by thus sowing it at the beginning of March we never fail to have an abundant supply.—W. W.

Auriculas.—We are now in the midst of preparations for exhibiting our Auriculas, not wholly welcome work, inasmuch as they, as a matter of course, must consist of the best plants and the choicest varieties, and they do not always come home in quite such good condition as that in which they were before being removed from home. It is, too, a very anxious time for the cultivator. Some of the choicest kinds are very scarce, and if any accident happen to them it is sometimes difficult to get another plant of the same sort. As a set-off, however, to all this an exhibition of this kind affords an opportunity for growers from all parts of the country to meet together and discuss matters relating to Auriculas. The general public also have an opportunity which would not otherwise be afforded them of seeing the plants. As Auriculas go out of bloom, if it be not intended to save seeds, the flowers should be pinched off as soon as they fade, leaving part of the footstalks. If the stem be broken off the portion that is left does not dry up, but dies off moist down to the centre, and sometimes kills the plants. Now is the time to hybridise, in order to obtain seeds that will produce new and good

varieties. Green-edged varieties should be crossed with flowers of the same section; grey-edged with grey-edged, and so on. In the case of Alpines the light-edged flowers with white centres should be crossed with others of the same class. Shaded-edged flowers are most esteemed, and such only should be used for parents.

Carnations and Picotees.—Plants in beds and borders are now starting into growth, and will not succeed if neglected. Make them firm round the roots by pressing down the soil with the fingers, and, if necessary, a short stick should be placed to any weakly subjects. See that the surface of the beds is stirred up and that weeds are removed while they are in a small state. By this time the earliest-rooted plants of the perpetual-flowering section ought to have been potted off, and on the care taken of them now depends whether they will gladden the cultivator with their beautiful sweet-smelling flowers at Christmas or not. The plants should be encouraged with a little warmth during cold weather, but they must be placed near the glass, and where a free circulation of air can be admitted amongst them. Pot off others as they require it, using small pots. Seeds of the different sections may also be sown in pots, placing them in a hotbed.

Hollyhocks.—All these ought to be planted out by this time in beds or borders; even the spring-propagated plants should be put out at once, if not already done, and great care should be taken in planting them, especially if the spikes are intended for exhibition. Some good loam mixed with a third part of rotten manure should be placed round the roots. It is by paying attention to minute details that success is achieved.

Pansies.—These require continual attention. Now wireworm and the leather-coated grub will be troublesome underground, and must be looked for if the beds indicate their presence. For "when the flowers fall off in quantity" (p. 305) read "quality." The meaning is this: A show Pansy will continue to flower until the character of the blooms are so deteriorated that the variety cannot be recognised; in that case pick all the blooms off and surface the soil round the roots with rich compost; this will restore the blooms again to their original size and quality.

Hardy Primulas.—The most useful at present are *P. æmœna* and its varieties—hardy kinds enough; but they do not stand well out-of-doors, owing to damp and frost. In cold frames they stand severe frost with impunity. We leave the plants in cold frames until the flowers open, when they are removed to the greenhouse. *Primula japonica* sometimes flowers well in pots, and, although this variety has not quite realised the expectations formed of it, still it should be grown for the sake of variety. Green fly persistently attacks it, and also red spider, pests which must be destroyed. In short, all this class of plants grow and flower freely in cold frames, and should be removed to the greenhouse when in flower.

Tulips.—These are now becoming interesting; their flower-buds are rising strongly. They are later this year than usual. Ours are fully exposed to the weather, and, though frosts by night and keen, cutting winds by day have been the rule rather than the exception, not a leaf or bud is injured. If the surface of the beds has not been dressed with rotten manure, that should at once be done. The different species of Tulips that have been introduced recently are very interesting, some even very beautiful, and they form a distinct and pleasing feature in beds or borders. They can also be grown in pots in cold frames, using light soil in which to plant them. The bulbs of some of them are small, and, therefore, they do not require to be covered deeply.—J. DOUGLAS.

Conservatory.

If a sufficient number of Azaleas, Epacris, and other hard wooded, spring-flowering plants have been retarded, there will be little difficulty in keeping conservatories now fully furnished with blooming subjects, as where there is at command a small house not much under the influence of direct sun, there is no reason why a continuous supply of Azaleas, which are the most effective of spring flowerers, should not be at hand all through the coming month, and it will invariably be found much more satisfactory to have their blooming thus dispersed over a lengthened period than to have a profusion for a time with scarcity afterwards. Even where there is no regular house or pit, with some spare lights fixed up temporarily during spring on the north side of a wall, a very useful retarding structure may be improvised, only whatever may be done in this direction the plants must not be subjected to insufficient light, as considerable shoot-growth is now going on, and any deficiency in this respect will have a most unfavourable influence upon the state of the plants next year. It is necessary to impress this upon young growers of this class of plants, as an idea is prevalent that no harm would accrue through their being kept for a time in an over dark situation, as the growth made under such conditions could be ripened by exposure afterwards; yet this is by no means the case, as leaves that

are formed under insufficient light are so far wanting in texture that no after treatment can set them right; be the plants of an ever-green, semi-evergreen, or deciduous character, it is of the greatest importance that their leafage be produced under conditions that will admit of its endurance for the full extent of its allotted time.

Oranges and Citrons.—These come more under the head of intermediate temperature subjects than those belonging to the greenhouse; for, although in this country they frequently receive little of the warm treatment at the time their growth is being made which they so much enjoy, still, to keep them in a vigorous, healthy state, with a full complement of luxuriant foliage, without which they have but a meagre appearance, they should now, when, in most cases, their growth will be about commencing, receive, if possible, warmer treatment than that which an ordinary greenhouse affords. Where there is a conservatory, kept, as usual, above a greenhouse temperature, they will do there whilst they are making their growth, but they should be set where they can be liberally syringed every day till it is completed, or they will succeed in a late Vinery, but the latter is only a make-shift sort of place; for, although they enjoy a little shade from bright sunshine whilst growth is in progress, still the dense foliage of the Vines continuously overhead excludes more light than is desirable. In the cultivation of large specimens of either Oranges, Citrons, or Lemons, it is desirable that their growth be allowed a little more freedom than it often receives. By using the knife less, the trim appearance that these plants frequently have where every shoot is cut back to an even surface, like the standard Bays so much used on the Continent, will be obliterated.

Greenhouse.

Standard Heliotropes and Habrothamnus.—Standard plants are often considered in themselves not very striking objects, but they are most useful in combination with others of a dwarfer character, as by their use the disagreeable even surface frequently present in greenhouses and conservatories is avoided. The above two subjects are particularly adapted for growing in this form, and the present is the most suitable time through the season for preparing them. They may consist of established plants, headed down to near the collar; when broken into growth the shoots should be thinned to a single stem, which should have a stick for its support, and should be run up to the height required, which may be from 3 ft. to 5 ft., according to the size or description of the structure which they are intended to occupy, and the plants with which they are to be associated when in flower. After the desired height has been reached stopping must be resorted to, and continued until the heads have attained a sufficient number of shoots. If headed-down plants like these are employed, as soon as they have fairly broken they should be turned out of the pots, a portion of the old worn-out soil should be removed, and more root-room should be given them, using tolerably rich soil. Thus managed, useful sized examples may be had by autumn, at which time their flowering will be found very acceptable. If established plants be wanting, it will be necessary to proceed in the usual way with cuttings, which, if treated liberally as regards pot room, will soon reach a serviceable size. In reference to the Heliotrope, so much esteemed for its perfume, it is doubtful if any of the new varieties are better than or equal for this purpose to the old original kind, which still appears to have the preference with growers for market.

Brugmansias.—Old plants of these that were cut back and started some time ago will now have made a certain amount of growth, and may, if they require it, receive larger pots, or have the surface renewed with fresh soil, keeping them in any available structure where they will get plenty of light and air, so as to keep their shoots short and stocky, which latter is essential to a vigorous head of bloom.

Greenhouse Rhododendrons.—These beautiful spring-flowering plants will be found to be most useful where large conservatories have to be kept gay; being almost hardy, they may be placed out-of-doors during the summer and autumn after their growth is made, which is a great advantage, and in winter they may be put into pits, Vineries, or anywhere where space can be found for them. Amongst the best are Countess of Haddington, bluish white; Gibsoni, a compact-growing, free-flowering, white kind with small foliage; javanicum, bright orange; Prince of Wales, orange-red; Princess Mary, white, tinged with pink; Thomsoni, scarlet; Veitchianum, white, tinged with yellow, the petals being fringed; Edgworthi, white, sweet-scented; retusum, orange-red; Princess Alice, bluish-white; fragrantissimum, bluish-white; and, for a roomy situation, Nuttallii is one of the best; it bears large heads of very large white funnel-shaped flowers; these will all succeed in ordinary peat soil, and do not require so much pot-room as do many plants of similar growth and habit. After blooming they will make their growth in any greenhouse or pit, during which time they must be plentifully sup-

plied with water, and after the flowers have formed they can be set out-of-doors.

Greenhouse Dracænas.—These, especially whilst confined to a small or medium size, can be used for so many purposes that they are almost indispensable, but it is necessary to keep up a continuous supply of young ones, as the larger stock will come in for use where smaller plants would not be so effective. When they get naked and leggy it is well to take off their heads, putting these singly in pots just sufficiently large to steady them, and subjecting them to a warm, confined, moist atmosphere, treatment under which they will soon root. The stocks, after the heads are removed, if placed in stove heat will, before long, push out a number of shoots that can be taken off as they get large enough and rooted, or a portion of the stems may be cut into lengths of 1 in. or 2 in.; these, if treated like cuttings in warmth, will break and form roots in a very short time, making useful little plants in eighteen months.

Callas are most serviceable when grown with single crowns that can be flowered in 6-in. pots; a plentiful supply of this size will be found of very much more use than large specimens. The flowers are of such a distinct and striking character, that one bloom is frequently as effective as two or three, and when sufficient numbers are grown to admit of their being brought into flower in succession, there is no difficulty in a supply being kept up from Christmas until late in the spring, but where Callas are grown in quantity it is best to turn them out in summer. Specimens that have flowered, consisting of several crowns, should now be taken out of their pots and divided, putting them in a row in a light situation in a well-prepared piece of ground about 1 ft. apart, supplying them sufficiently with water through the season until the beginning of September, when they can be taken up and placed in pots of the size above mentioned, in which they will bloom. This I have tried to be the most satisfactory way of growing them which I ever tried.

Early-flowering Pelargoniums.—Independently of the zonal section of these, which, when well managed, can be easily had in bloom all through the winter and spring, there are numbers of early-flowering varieties that partake more of the character of the large-bloomed or show kinds than of the zonals. These are not equal, from a florist's point of view, in the form of their flowers, to the best exhibition sorts; but, nevertheless, they are such as are largely cultivated by the London market growers. Many of them have only local names, and often not cultivated by any except those who grow for market, yet they are most valuable as decorative subjects, being of a very floriferous habit, sturdy, short-jointed, and able to bear a considerable amount of warmth to bring them into flower. If these were more generally cultivated in private establishments they would be found to be of great use at this time of the year, as they are far better than the endless presence of red and pink zonals.

Large-flowered and Fancy Pelargoniums.—The blooms of these will now be fully formed, and will have made some progress, and be indeed in a condition to be benefitted by the application of manure-water, which, if used too early in the season, is apt to cause a disposition to produce leaves at the expense of flowers. If sufficient ties and supports have not been already given to the plants to keep them in a presentable state, at the same time avoiding all stiff, formal training, this should at once be attended to.

Chrysanthemums.—These are so easily grown and tenacious of life that in the press of other matters at this time of the year they often get neglected; yet, though so easily managed, want of attention is sure to result in a deficiency of flowers when they come to be wanted. A cold frame up to the time when the plants have got fairly established in 5-in. or 6-in. pots, with plenty of air, and fully exposed to the light is the most suitable place for them. If cuttings were put in in November or December, and kept in a cool place just out of the reach of frost, they will, ere this, have been transferred to pots of the size just named. Such as were propagated later through the winter must, as soon as the little pots they occupied are filled with roots, be at once moved into larger ones, stopping the shoots of those that are intended to be grown in the usual bushy form; but I should recommend a portion to be grown in the shape of low standards on a single stem from 2 ft. to 2½ ft. in height, and not stopped until they have reached this, after which, nip out the points two or three times, so as to induce them to break a sufficient number of shoots to form the head, and all on from the first, removing any side breaks below these or sucker growths from the bottom; but for growing in this way the freest flowering, medium-sized kinds should be selected, as many of the largest bloomed varieties that are not able to perfect so many flowers are not so well adapted for that. Mrs. Randle, white, incurved; Mrs. Dixon, rich yellow, incurved; George Glenny, straw coloured, incurved (both the latter are sports from the unsurpassed Mrs. Randle, differing in no way from that

variety except in colour); Julie Lagravère, velvety crimson; Hermione, blush; Annie Salter, yellow; Lady Talfourd, rosy-lilac; purpleum elegans, violet-crimson; and others of similar habit will all be found suitable for growing in the form of standards.—T. BAINES.

Hardy Fruit.

Here, North Hants, on the mornings of the 12th and 13th inst., we registered 8° and 9° of frost respectively, and the same on the 18th and 19th, and this, with the wind continually blowing from the north and north-east, has shattered our hopes of a full Apricot crop, for, though the trees were well protected with scrim canvas, many of the fruits, which were the size of French Beans, are quite frozen through, and, curiously enough, those only just setting seem all right. Happily, Pears, Plums, and Cherries have not yet unfolded their blossoms, and therefore seem uninjured. Such weather almost makes one lose heart, but still every effort must be made to save fruit-buds from further injury by protection of some kind. Gooseberry and Currant bushes should have dry Bracken, straw, or hay shaken over them; some that have been thus covered are quite uninjured. Straw litter is somewhat unsightly, but little is thought of this so long as the fruit is saved. Any grafting yet on hand should have immediate attention, and after sharp frosts the clay put round the grafts should be examined, as the frost may cause it to crumble off. It is a good plan, when the operation is first done, to bind over the clay either hay or Moss, which both preserves the clay from being cracked by frost or drying winds, and from being washed off by heavy rains. Apricots are now fit to disbud; as a rule, this is best done as soon as the fruit is set, and before the shoots have attained much size. Some cultivators do not disbud Apricots, but in lieu pinch out the points of all growths that are not required to furnish the wall as soon as two leaves are formed. Of course this persistent pinching induces the formation of a mass of fruit-buds, indeed, far too many, and hence our advocacy of disbudbing in a reasonable degree, say to about one-third the extent as that required by Peaches; even then there will be abundance of shoots for the formation of fruit spurs, and these should be kept constantly stopped throughout the summer. Thinning the fruit betimes is also an important matter; usually it sets in clusters where there is space only for a single fruit, so it must be obvious to all that an early removal of the surplus produce is of importance. If any leaves curl up, grubs will be found ensconced in them, and should be searched for and destroyed. With the exception of the liability of Apricots to canker, this leaf-rolling maggot is about the only enemy they have to contend against. Young, newly planted trees are apt to grow too strongly, more especially the uppermost shoots. In order to check this tendency it is well to stop the leading shoots twice or so during the season; a more equable distribution of sap to all parts of the tree is thus ensured, and, therefore, a more even growth. Such remarks are not only applicable to newly-planted Apricots, but to all other kinds of fruit trees, and not only to wall-trained trees, but also to nearly all others. Peaches are in magnificent blossom, the flowers being full and well developed, and, setting aside accidents, this should be a good Peach year. Where the trees and walls were not dressed in winter it is more than probable that green or black fly will soon make their appearance, and if, when first perceived, the trees be well dusted over with Tobacco powder, or occasionally syringed with soapy water, there will soon be an end of them. This is a matter that will not be put off without serious injury being the result, as these pests soon gain the mastery. "Prevention is better than cure;" hence the great importance of winter dressing, which I have so frequently insisted on, as well as early disbudbing. Still, let the trees be sheltered nightly; the fruit will swell more kindly by avoiding extremes of either heat or cold, therefore, for the present, the blinds should be down for a couple of hours during the brightest sunshine, and as soon as all the fruit is set a vigorous syringing with tepid water will help to dislodge the fallen blossoms, and loosen any that may still adhere to the young fruit. Apples are fuller of flower-buds than they have been for some years, but bullfinches are now playing sad havoc with them. These little depredators were so late this year in their attacks that we had begun to think the winter had thinned them, but such is not the case. We continue to shoot them in self-defence, having in vain tried all other known remedies. Strawberries have gone through the winter with but little apparent injury, and they are now making fine growth. Any decayed leaves may be removed carefully so as not to injure the new foliage. If they have not yet received a surface mulching of well-rotted manure, that should at once be done, but previously hand-weed. The surface roots of Strawberry plants are their mainstay, and no digging or deep hoeing should therefore even be practised amongst them. The plants should not continue more than two years on the same ground, and, therefore, if it be well trenched and manured previous to planting, the surface-mulching recommended will be ample nourishment without the doubtful proceeding sometimes resorted to of forking in rotten manure.

Plantations made now of the earliest-forced plants will produce very early runners, and if the first flowers that show themselves after they get established be picked off, successional blooms will produce a fine crop of autumn fruit.—W. W.

Extracts from my Diary—April 28 to May 3.

FLOWERS.—Shifting Chrysanthemums out of cutting pots singly into 5-in. ones; also shifting established plants. Shifting Gloxinias. Potting Mignonette for growing into standards. Planting out old Chrysanthemums on north border. Potting Calceolarias out of 6-in. pots into 8-in. ones. Putting in cuttings of Bouvardias and Verbenas for stock. Potting *Pereskia* stocks on which to graft *Epiphyllums*. Moving *Paragonium* from Vineries to cold houses. Putting in cuttings of Violets under handlights, and planting old plants outside under north wall. FRUIT.—Planting Melons of various kinds. Thinning the fruit of Strawberries. Disbudding Peaches and Nectarines and thinning the fruit. Tying and pruning outdoor Fig trees. Thinning Grapes. Clearing out fruit-room. Watering cold Peach house borders. Tying Vines. Watering outside border of early Vinery. VEGETABLES.—Shifting Tomatoes out of seed-boxes into 5-in. pots; also Vegetable Marrows out of seed-pans into pots of the same size. Making a bed for Vegetable Marrows with old Cabbage stumps and manure. Clearing away Brussels Sprouts and preparing border for the reception of other crops. Tying and stopping Cucumbers. Planting Garlic and Shallots. Sowing first batch of Scarlet Runner Beans. Sowing Cauliflower and Cabbage seed; also Mustard and Cress.—R. GILBERT, *Burghley*.

PEAR CULTURE IN MARKET GARDENS.

MUCH attention has of late years been paid by market gardeners to the culture of Pears, which, if of good quality, generally fetch good prices in the market, and growers are now beginning to discover the importance of growing the best kinds, as trees that bear dozens of large, well-flavoured fruit, pay much better than those which produce bushels of Pears of inferior quality; therefore, as old trees wear out, better sorts are planted to fill their places. Pear trees are nearly the only fruits grown on walls in market gardens, *i.e.*, where walls exist, which is in but few places, and in some cases where these are low the trees are planted on one side, and trained over the top and down the other side. Occasionally they may also be found in the form of espaliers.

CRACKING STOPPED BY GRAFTING.—Pears of the commoner kinds are chiefly grown on the old-fashioned standard run-wild system, no pruning being given but what is done with the saw; and, in a good season, it is wonderful how heavily the trees are laden with fruit. These standards have been "worked" on the Pear stock, which forms a clean stem, the branches usually springing from near the union of the stock with the scion. There are dwarf Pear trees, too, and many that succeed better on the Quince than on the Pear. Market gardeners generally are not, however, very particular about their stocks, for they get the bulk of their trees at the nurseries, and what they graft themselves is usually done on whatever stock they have at hand, be it seedling, sucker, or layer of Pear or Quince. They practise grafting more on old and worn-out trees than on young stocks, and for this purpose they head back the trees in winter or early in spring, either at pruning or digging time; the scions, after being selected, are "heeled in" until March, when they are put on the trees. Grafting more than one kind of Pear on a tree is said to be a preventive of fruit cracking during the swelling period. A large grower near London, who possesses the finest natural Pear-tree soil in the district, states that a somewhat light yet deep, substantial, hazelly loam suits Pears best. In reference to cracking, he found that, although the trees were in a thriving and healthy condition, and annually set good crops of fruit, yet at gathering time scarcely a half sieveful of good marketable Pears could be obtained from them, the fruits being invariably cracked. This induced him to try the effect of grafting more than one sort on each tree, and the result

proved most satisfactory; for, not only did the grafted portions produce excellent fruit, but the original kinds no longer cracked; on the contrary, they produced fruit of exceedingly fine quality, well-formed and symmetrical. Finding grafting in this way successful in a few cases, he extended the practice throughout his orchards; therefore, where one kind of Pear grew alone on a tree, now there are at least three sorts, each apparently being of material benefit to the other; for example, a number of trees, formerly *Beurré Diel* only, now bear huge branches of *Beurré Bosc* and *Louise Bonne*, the trees being furnished in good seasons with large crops of these three sorts. Pear trees are not, however, all tall standards, for some are as dwarf and symmetrical as one could wish to see. Naturally-grown bushes are preferred to rigid French pyramids, as the former bear more fruit and resist wind better than pyramids. Some kinds of Pear trees have naturally a pyramidal habit, which, as a matter of course, is encouraged. Bush Pears are in rows, about 9 ft. apart and 8 ft. asunder in the row, and some are even closer than that. At Mr. Daucers's are some of the finest and most vigorous bush or pyramid Pears on the Quince stock to be found anywhere, and in nearly every case the trees bear large crops of splendid fruit.

VARIETIES.—Among the varieties grown on the above system are *Beurré Hardy*, a clean and shapely tree, and a good cropping variety when well managed; *Doyenné du Comice*, one of the finest-flavoured of all Pears, and one which is very prolific; *Marie Louise*, *Marie Louise d'Uccle*, *Huyshe's Victoria*, and other varieties. *Souvenir du Congrès*, an excellent fruit, raised as a seedling from *Williams' Bon Chrétien*, does well, and bears large, highly-coloured fruits on young-grafted bush trees; these fruits average about two to the pound, and possess a flavour resembling that of its parent, but more aromatic. *Louise Bonne* of *Jersey*, when cut in well, is very productive. The *Duck's Egg* does well, and is a valuable early market Pear. Of *Williams' Bon Chrétien* no fewer than 100 bushels were sent to market from one garden alone in one day. *Beurré Bosc* is by some regarded as the king of market Pears, on account of its prolific bearing habit and handsomely-formed and large-sized fruits, of fine quality. One of the best Pears that we have seen in the market of late years is one grown by Mr. Wilmot, of *Iseworth*, named *Pitmaston Duchess*. Some of the specimens of this remind one, as regards size, of the *Belle Angevine* (*Uvedale's St. Germain*), and their flavour resembles that of *Marie Louise*. Some fruits of this variety have been known to weigh 1½ lb. This Pear, therefore, finds a ready sale in the market.

Among early market Pears ripe in July and August may be mentioned *Beurré de l'Assomption*, a large-sized, lemon-yellow kind; *Williams' Bon Chrétien*, *Citron des Carmes*, a medium-sized fruit and an abundant bearer; and *Madame Treve*. These are succeeded by *Belle et Bonne*, *Beurré d'Ananlis*, *Beurré Superfin*, *Fondante d'Automne*, *Gratioli* of *Jersey*, *Hazel*, *Louise Bonne*, *Louise Bonne* of *Jersey*, *Marie Louise d'Uccle*, *Autumn Nelis*, and *Seckle*; these keep up a supply till the end of October, after which come into use until Christmas, *Vicar of Winkfield*, *Winter Nelis*, *Napoleon*, *Marie Louise*, *Duchesse d'Angoulême*, *Doyenné du Comice*, *Althorp Crassane*, *Colmar d'Aremberg*, *Bishop's Thumb*, *Beurré Léon le Clerc*, *Beurré Hardy*, *Beurré de Capiaumont*, *Beurré Clairgeau*, *Beurré Bosc*, and *Beurré Bachelier*. Amongst kinds which come into use after the new year has set in may be named *Bergamotte Esperen*, *Glou Moreau*, *Knight's Monarch*, and *Easter Beurré*; many other kinds are also grown for market, but these form the chief supply.

CROPPING BENEATH THE TREES AND STORING.—As with other orchard trees where large Pears exist, the ground under-

neath is cropped with vegetables or bush fruits, but where dwarf pyramids are grown this system is not so much practised; the ground is, however, kept clean by hoeing, and some market gardeners mulch heavily with manure in summer, and in winter the manure is forked into the ground. Most growers dispose of their Pears when gathered, leaving the dealers to find storage room, but in a few cases where good storage can be found at home, they are kept till they are nearly ripe before they are marketed. A great proportion of the best dessert Pears seen in the English markets are imported from France and the Channel Islands. Indeed, California and many parts of Eastern America are likely to play an important part as regards furnishing Pears to the English markets; but the distance and length of time that elapses from the period when the fruit is packed till it is unpacked in England sometimes tells badly in regard to Pears, a circumstance favourable to English growers. C. W. S.

THE FLOWER GARDEN.

ALSTREMERIAS AND THEIR CULTURE.

THOSE who have never grown these beautiful Lily-like flowers can have no idea what a grand display they make in beds or borders grown in masses, or the great value they are for cutting to furnish vases, in which they stand longer fresh than anything else I am acquainted with, except it be the old and well-known *Calla* and *Amaryllis*, or a few things of that kind, with large porous stems that take up such quantities of water. This the *Alstroemerias* do, too, owing to the peculiar structure of their stalks, which are tubular, and up these it is drawn by capillary attraction, so that the blooms are always well fed. Not only are they very telling in beds and borders, but they are equally effective planted in masses near the margins of woodland walks, where when once they become established they look quite naturalised, and soon take care of themselves. Many of our herbaceous plants may be used to great advantage in this way, especially such as are strong growing, and just at this time of year when they are being overhauled there are always plenty that want reducing, the divisions from which, taken care of and planted annually as they can be spared, soon make a show, and greatly enrich any place and add to its interest. To start with such plants as *Alstroemerias*, however, it is necessary that the ground should be previously prepared by being broken up or trenched, and a supply of plants got in pots for turning out, or seed sown where they are to stand. *Alstroemerias* being difficult to transplant or divide, their stems and tuberous roots penetrating deep down in the earth, and the less they are interfered with the better. A loose sandy soil is the most suitable for them, as, being of a somewhat tender nature, it is essential that they have a free root-run with plenty of drainage; if they can have this and an open, sunny spot, they grow with great vigour, and form magnificent masses studded so thickly with flowers that they are quite a sight to behold. The tubers being just now on the move, the present is the proper time to begin with them, as they travel with safety, and have the whole season before them to get a thorough hold ere the winter sets in. To make them perfectly safe from frost, they should be planted 6 in. deep, and in the autumn it is always advisable to give the surface of the ground a mulching of rotten leaves or any decomposed vegetable matter of that kind, as, being so thoroughly non-conducting, the crowns are then out of harm's way. Unless sown in heat now, or in the open soil as soon as gathered, seeds of *Alstroemerias* are slow in germinating, and often lie dormant a year, which, being the case, the pans or beds they may be placed in should not be disturbed any more than is requisite for keeping them clean. S. D.

Myosotis dissitiflora.—The only way to test the merits of cuttings and seedlings in the case of this *Forget-me-not* is to plant them separately for comparison. I am aware that they grow and flower in favourable seasons tolerably well from cuttings, but not with the luxuriance of seedling plants, which, if procurable in quantity, I would always prefer to dividing old plants; that is only resorted to as a makeshift. As regards Mr. Legg's suggestion that a supply should be struck in frames in heat, I question whether, even if that were practicable, it would be a means of rendering the plants better able to withstand such a winter as that which we have just passed through. We have too many tender subjects already to attempt coddling hardy ones under glass.—J. GROOM, *Linton*.

THE ANNUAL PEAS.

The Sweet Pea (*Lathyrus odoratus*).—Of the many kinds of hardy annuals which we now have for embellishing the outside garden in summer, few are so universally esteemed as Sweet Peas. The variation in the colours, from the purest white throughout almost every conceivable shade to purplish-black, the delightful perfume, the facility with which they may be grown, and the many uses to which they can be applied in garden decoration, all contribute to place them amongst the best of annuals. As a temporary screen for shutting out unsightly objects, or for rapidly covering arbours or trellis-work, or as floral fences for the protection of more tender plants, these annual Peas are unsurpassed; and, lastly, but not least, they make charming plants for the wild garden associated with such companions as the Canary Creeper, the various kinds of *Convolvulus* and *Clematis*, each striving as it were to rival each other in beauty. Of late years several well-marked varieties have been raised, as a

one of our rare native wild flowers, which grows on Grassy banks in various places.

The culture of all the foregoing is, of course, of the simplest character; they should be sown from March till June in the open border. They will repay liberal treatment and an open position, which oftentimes they do not get; and if care be taken to leave no more pods on the plants than are necessary for seed, the flowers will be more plentifully produced and the season prolonged. Sweet Peas are also quite amenable to pot culture for greenhouse decoration, and very pretty they are treated in that way. In order to obtain flowering plants earlier than they otherwise would be they may be sown in autumn and protected during winter, when they will flower early in spring. W. G.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Summer Treatment of Double Primroses.—I have been interested with what "S. D." has written (p. 328) respecting the beauty and comparative rarity of these charming spring flowers. It is a fact that, with the exception of the double white and lilac kinds, all others are generally but little known in gardens. For this there is an obvious reason. Few plants are more difficult to keep alive during our hot summer months than the rich crimson, purple, and yellow kinds, and when lost cultivators do not care to replace them. There can be little doubt that thrips, generated by a heated, dry atmosphere, is a great enemy to these plants, and that their cultivation anywhere in the southern part of the kingdom is full of difficulty. The only kinds that are reliable are the white, lilac, early sulphur, and the rose, the latter a very distinct large-flowered sort. These Primroses are impatient of frequent removal, and should be undisturbed for several years. Of the yellow kinds there are three, the Giant Yellow, Late Yellow (these two differ chiefly in the appearance of the foliage), and a large form introduced last year from the Continent by Messrs. Veitch. The colour of the blooms in each case is clear straw-yellow. Unless a cool, shady situation can be found for these yellow, purple, and crimson kinds, it is useless to plant them out. Stocks of them are generally obtained from Ireland or the north of Scotland.—A. D.

—It is pleasant to find THE GARDEN recalling the memories of half-forgotten flowers, and doing much to induce people to try and bring them again into cultivation. Its correspondent, who writes so truly (p. 328) of the Primrose, deserves the thanks of those who love the modest beauties of a time gone by. "Old-fashioned" ought not to be a term of reproach in the garden, when loveliness and fragrance are concerned; and those who, while carefully cultivating all that is new and ornamental, would not willingly let die the favourites of the century's earlier days, are doing good service, and are worthy of commendation. A lady, writing in the "Floricultural Cabinet," in May, 1846, enumerates the following very double and most distinct varieties of Primrose as forming her collection: "Crimson, white, purple, straw colour, rose, deep yellow, pink, buff, lilac, and red." The conductor, Mr. Joseph Harrison, in the number for December, 1843, had mentioned "flesh, violet, and copper" coloured varieties. Are these to be had now? Messrs. Rodger, McClelland & Co., Newry, whose collection contains so many rare plants, have got "yellow, purple, crimson, lilac, blush, and rose." If any reader of THE GARDEN, who has got other varieties, would assist in making a complete list, a general benefit would be conferred upon gardens and gardening. My own flower-beds only contain white, yellow, crimson, purple, and lilac varieties, though some years ago several others were to be found there.—WM. JOHNSTON, Ballykilbeg, Co. Down.

Outdoor Primroses.—I heartily commend "J. P.'s" remarks respecting those to the attention of all lovers of hardy flowers, and as we have them in quantity, both double and single in every obtainable shade of colour, I can speak with certainty as to their merits. We have used them largely for table decoration, for, as "J. P." remarks, they are easily arranged in Lycopod or Moss, and look well either by day or under artificial light. For people in London during the early part of the season, a few tins filled with green Moss, in which bunches of Primroses are placed, garnished with their own foliage, form a decoration fit to set before a queen, and the double ones make charming companion button-hole bouquets with just a spray of some other colour. During the present inclement spring the Primrose is nearly the only flower that has been able to brave the wind for any length of time, and our best beds of it at present are those partially overshadowed by the branches of drooping Conifers and Hollies. The shelter of these in winter and their shade in summer form the principal item of success in the cultivation of these lovely flowers. At present, our double varieties are in full bloom, and most beautiful they are; why they are not more generally grown is to me a mystery.—J. GROOM, Linton Park, Maidstone.

glance at any seed catalogue will show, and of these some of the best have been illustrated in the pages of THE GARDEN in the form of coloured plates.

Though none of the other annual kinds of *Lathyrus* can surpass the Sweet Pea, there are several other kinds which make pretty border plants. Of these the best is the Tanger Pea (*L. tingianus*), which grows about 3 ft. high, and produces small, dark red-purple flowers in abundance. The Chickling Vetch (*L. sativus*) is another pretty kind, with flowers varying from pure white to deep purple. The variety *azureus* is a remarkably elegant dwarf kind, that bears a profusion of clear blue flowers; *L. s. coloratus* has flowers white, purple, and blue; *L. Gorgoni*, which grows about 2 ft. in height, is a very desirable plant, with pale salmon-coloured flowers; *L. articulatus*, *Clymenum*, and *calcaratus* are other pretty kinds, that are quite suitable for flower borders; as is also the Crimson Vetchling, with numerous small crimson flowers and Grass-like foliage. This is

THE KITCHEN GARDEN.

BRUSSELS SPROUTS.

DURING a winter like the past, Brussels Sprouts is by far the most useful vegetable which we possess. Thousands of Broccoli have perished before forming a vestige of head or flower; Cabbages and Savoy's have rotted off their stems, and those which have escaped are "bolting;" but Brussels Sprouts have furnished a supply of excellent food during every day in the most severe weather, and they are now about the only green vegetable to be had in the open quarters of the garden. On this account, therefore, I am growing Brussels Sprouts much more extensively this summer than hitherto, and I would strongly recommend everybody to do the same. Whether large or small, the Sprouts will be found most useful during winter and spring; and, let the weather be what it may, a large supply of Sprouts may confidently be depended on; nor need there be any fear of their failing to come to maturity, or of their becoming useless, if the same attention be devoted to them which is paid to ordinary Cabbage. I know, indeed, of no vegetable that will give so much satisfaction with so little attention. We have some hundreds of them planted out in their permanent quarters now and some thousands in seed-beds. If possible, the plants should be planted where they are to stand not later than the first or second week in May. We have tried them early and late, and find the first week in May to be the best, as when the Sprouts are not well formed and hard before winter weather sets in, they do not swell so well afterwards, nor do they keep so well. When they are fully swelled by the end of October, they will keep as sound and hard as marbles until the following May; and in order to secure such a result, it is well worth trying to get good plants up early in spring.

Our earliest plants were raised in a box in a little heat in February, dibbled into a frame on a slight hotbed in March, and, finally, planted early in April. Our earliest seed, sown in the open border in the first week in March, will be ready to plant in May, and the produce will be covered from top to bottom with fine sprouts by November. Those who have no plants to put out early in May would find it answer their purpose to buy a few hundreds. Some think that Brussels Sprouts may be grown anywhere, and they are right. They may be grown well in odd corners and amongst other dwarf-growing crops; for instance, we plant many of our Potatoes 3 ft. from row to row, and plant Brussels Sprouts between them. When the Sprouts are planted just about the same time as the Potatoes they soon grow up and get well out of the way before the Potato stems have any effect on them, but our best Sprouts are grown 3 ft. plant from plant all ways. This distance may appear great at first, when the plants are small, but when they get up to about 4 ft. in height it is not too much for them, and those planted wide always stand better in winter than those that are close, besides yielding finer Sprouts. Some of ours were planted only 18 in. apart last year, and the ground was soon covered with a mass of foliage, which caused the stems to run up long and weakly, and before the Sprouts were thoroughly formed many of the stems were bent down and lying half their length on the ground. In order to secure the best results from Brussels Sprouts this must be avoided; they should never be planted closer than 2 ft. each way.

A good deep soil, well manured, suits Brussels Sprouts best, and when the soil is poor plenty of good manure placed close to the roots will soon counterbalance other deficiencies. Nearly all varieties of the Brussels Sprout are good when properly cultivated, but preference might be given to Gilbert's Selected Burghley, an excellent variety.

CAMBRIAN.

TOMATOES FROM CUTTINGS.

I do not see that either of your correspondents (pp. 296 and 309) mentions this plan of propagating Tomatoes, which, under some circumstances, is a good one. Here, as we need quantities of the fruit as long as we can conveniently have it, we propagate both by means of seed and cuttings, and set the plants about the houses wherever there is room for them. Spare Tomatoes can always be disposed of more remuneratively than most other vegetables. We have to buy large quantities of Newtown Pippin Apples and Jersey Pears while they are in season, the cost of which is largely defrayed by means of the money obtained for spare Tomatoes, which dealers buy readily at about 6d. per lb., and it does not take many fruit to weigh that much.

Our cutting plants were struck last November and are now about 5 ft. high and bearing freely, though the fruit is not ripe yet, and could we spare the house for them I have no doubt they would go on bearing till this time next year. As it is they will be allowed to bear till about Christmas, perhaps. The plants would have had plenty of ripe fruit upon them in February or March if they could have been

placed in their present quarters sooner, but the house was only emptied at the beginning of March for the Tomatoes, which were at the same time transferred to 12-in. pots from the 5-in. ones in which they had stood all the winter. I think it was at Garston Vineyard where I once saw a large quantity of cutting plants in August that were newly struck for fruiting from Christmas onwards. Cuttings grow almost as vigorously as seedlings, and are more fruitful.

Our seedling plants are now about 18 in. high, and are being placed in vacant spaces about the late Peach houses, as the temperature of these structures gets high enough for them. Tomatoes will grow and bear in any heat, from our outdoor summer temperature to that of a warm stove. In our high and cold situation, however, they never colour out-of-doors, even in the most favourable exposures, unless the plants be put out when the fruit is far advanced, when we find it better to keep them inside. There are generally spare frames or room in gardens during some part of the summer where such subjects can be grown; we have always filled our early Potato frames with Tomatoes about this season, and to keep the fruit from coming in contact with the soil the branches are trained over a few old Pea sticks laid on the bed, and which answer the purpose perfectly.

J. S. W.

ASPARAGUS PLANTING.

As the season of planting Asparagus approaches, the insertion of this little diagram, showing the open way of planting, may remind

Ground Plan of Asparagus Bed.

our readers of the advantages of that system. The illustrations show, in section and plan, the open mode of planting in a shallow trench without any special preparation of the ground, provided it be of ordinary quality. Any good garden ground, for example, would

Section of Asparagus Bed.

not require manure the first year of planting; a little is given over the roots as the plants get older, the dressing being given in the autumn and washed down by the winter rains.

Variegated Kale.—We send you examples of our Leaf upon Leaf Winter Rainbow Kale for garnishing and for flower garden decoration during autumn, winter, and spring. We have many varieties of this Kale, the colours of which are very pretty. — FREEMAN & FREEMAN, Norwich. [The specimens sent, pale yellow, purple, and other colours tipped with green, are bright and effective, even after such a winter as that from which we have hardly yet escaped.]

Garden Labels.—I forward to you a label which differs from any other I have seen, and which seems to me to have some very good points about it. 1st. It is cheaper than any other label I know of, and the price, I should say, could be still very considerably reduced if it were made in quantity. 2nd. It has a very pleasant appearance in the flower border. The best part of Mr. Ellacombe's label is reproduced in it, viz., the way in which the name of the plant is written upon it. 3rd. It must be very durable, as the part that is made of wood does not touch the ground. 4th. It keeps an upright position, which is more than other labels have done with me after the late frosts. I saw this label in a rough form in an old-fashioned garden, and I like it so much that for the future I do not think I shall ever use anything else. — H. EWANK, St. John's, Ryde. [The label in question consists of a nearly square, thin, wooden head, painted first white and then black. In writing the name the black is pierced through so as to make the letters look white on a black groundwork. Two galvanised wires fixed in the bottom part of the head about 1 in. apart form steady and lasting supports.]

ANSWERS TO CORRESPONDENTS.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 22.

THE Conservatory at South Kensington held hundreds of beautiful plants on Tuesday last; but, perhaps, the greatest interest was concentrated in the show of Auriculas. These were superb in their way, and the Roses of Cheshunt and Waltham Cross were certainly of the loveliest ever seen at this season of the year. One bloom of the Hybrid Perpetual Madame Liabaud, too, in the choice group sent from the Veitchian collection was deservedly noticed as containing most of those qualities which go to make up perfection in that most perfect of all flowers, the Rose. Hebe might have selected so perfect a chalice, while the colour, nearly white with the most delicate suggestion of flesh in the centre, the fairest of Rose and Lily tints, was combined with a delicious rich and satisfying perfume. Amongst garden plants of tropical origin were many lovely Orchids, Palms, and Ferns—the loveliest of rosy Odontoglossums, with large flowers of satin like lustre, a citron-scented Cattleya, with flowers as bright in colours as those of golden Daffodils (*C. citrina*), and, perhaps, the smallest plant of one of the finest of all Orchids, *Laelia purpurata*, ever seen, the segments of snow-white petals, while the lip in itself had much of the colour and beauty of the amethyst and ruby combined. A new Lilac, with the largest and whitest of flowers from Lord Lonsborough's garden, vied in purity with the long petalled blossoms of a *Panacratium*-like plant from the time-honoured gardens at Sion House, which, under the name of *Hymenocallis macrostephana*, deserves the attention of all lovers of fair flowers. The assertion that dingy colours and grateful fragrance are often combined in flowers is especially true of an Australian shrub of especially graceful and floriferous habit of growth, *Boronia megastigma*, the colours of which are dark brown and dingy yellow, the perfume so distinct and pleasing that no conservatory should be without such a sweetly modest ornament. "The Roaring Moon of Daffodils" has long passed this spring, and April showers, albeit rather cold and ungenial ones, have attended the blooming of these old-fashioned favourites. Of varieties new and old, at least fifty were exhibited, their tints of soft yellow—sulphur, primrose, or orange—and white being most pleasingly represented together with considerable variations in form. Amongst the most noticeable was the large sulphur-coloured variety of the Hooped Pettecoat *Bulboodium*, which, in sweet co-partnership with the blue *Lithospermum prostratum*, crops up here and there in little colonies on the Western Pyrenees, especially near the lighthouse of Biarritz. The seedling *Narcissi* of the last few years are especially remarkable for their variety in form, colour, and stature, and are welcome to all those fond of outdoor flowers; and the same may be said of the numerous forms of hardy *Primrose* and *Polyanthus*, both new and old, which graced the show. The snow-white flowers of *Magnolia stellata*, several floriferous examples of which were sent from the Veitchian establishment, were most admired, and its beauty and fragrance at this season, albeit unattended by foliage of its own, will render it a welcome addition to the ranks of half-hardy shrubs, and if fresh greenery be required for contrast with its star-like petals, then the new and beautiful *Adiantum Williamsi*, or the lacinate form of *A. Rileyense*, shown by Mr. Smith, of Worcester, under the name of *A. alcicornis*, are both charming Ferns for such a purpose, or some of the pendent, crested forms of *Pteris serrulata*, of which one charming variety was exhibited, may be employed together with Palms and Cycads for associating with this *Magnolia* and other leafless spring flowers. The groups of decorative plants, comprising Orchids, Ferns, Palms, and forced flowers from the leading nurseries were much admired. Amongst plants curious as well as beautiful, or otherwise interesting, may be named the gracefully drooping flowered *Hibiscus schizopetalon*, introduced by Messrs. Veitch, the petals of which are recurved into an elegant cup-like shape, and are cut into segments almost as delicate as those of a filmy Fern, the long anther-fringed style adding to the other attractions of the flower. The North American Pitcher plants, or *Sarracenias*, were well represented by plants of *Sarracenia Drummondii* and its white variety, all in the most vigorous health, their long trumpet-like pitchers being in some cases nearly 2 ft. in height, most gracefully modelled, and in some cases richly coloured. A little tuft of *Venus' Flytrap* (*Dionaea muscipula*) bore tall scapes, terminated by rather large and showy *Primrose*-like flowers of pure white; and the *Mantis-like* or *Nautch* Gilly-like *Mantisia saltatoria*, brought by Mr. Green from Sir G. Macleay's garden, gained much attention from those interested in botanical curiosities. One of the most striking plants, however, in the whole exhibition was the specimen of the Giant *Viper's Bugloss* (*Echium Decaisneanum*), or *E. fastuosum*, also from Sir G. Macleay, the stout stems of which were clothed with stout,

Stokesia cyanea.—With me this forms plenty of flower-heads, but they will not open. My plants are now exactly in the same state that they were when placed in my warm greenhouse last October. How should I treat them?—H. BERNY. [The ill-success attending the culture of this handsome autumn-flowering, hardy perennial may, without doubt, be attributed to being placed in a warm greenhouse just at the commencement of the flowering season, for, like many other hardy plants of similar constitution, it hates the stagnant, humid atmosphere of glass houses, and naturally resents such treatment by not flowering. Being a native of Carolina and the Southern States, where a bright, dry autumn is the rule, a close imitation of such conditions is obviously most conducive to its successful treatment; and, therefore, in order to grow it to perfection, it should be placed in a fully exposed and sunny position in a light, rich soil, and should receive copious waterings during summer so as to encourage an early formation of flower-heads, but artificial waterings should be withdrawn towards the end of summer. In naturally dry localities, a hand-light placed over the plants at the flowering season will be found to be very beneficial, but it should be so arranged that it allows free admission of air on all sides, while it protects from excessive moisture.—W. G.]

Cyclamen Plunged out-of-doors in the Summer.—I should be glad to know if *Cyclamens* would do well if their pots were sunk in the ground under a north wall about the middle of May, and left there until they were potted for blooming again; also if it weakens them or otherwise injures them to retain some of their leaves all the year, as last year ours never completely died down; they were then only eighteen months old; also if it is right to set them in saucers of water instead of watering on the top when coming into bloom.—L. E. [The bulbs will do very well if treated as described, but the roots will be better preserved if the plants can be placed in a frame or under a heavy raincoat, which would do. I have just found that a few have remained in during the summer indicating a healthy state of the roots, such plants starting roots. Saucers are not necessary for *Cyclamens*, they should be watered in the usual manner, not allowing them to remain dry.—J. C.]

Primrose Grubs.—What are the enclosures grubs which devastate my *Primroses*? I find them embedded in the succulent roots, and the leaves turn brown, and the *Primrose* decays; how shall I destroy them?—J. O. [What you have sent are apparently the grubs of *Omorhynchus sulcatus*. Searching for and destroying them, and the plants will be the better for it. The parent weevils which can be found is the most likely way of getting rid of them.—W. W.]

Frost-bitten Roses.—Will any of your correspondents kindly give me a little advice as to the treatment of standard Roses a little injured by this last severe winter?—EUGENE E. P. LEGGE, *Court House, Linton Cheney, Dorset.* [Prune back to the first eyes that show signs of sound life.—ARTHUR W. P. [P.L.]

Metal Labels.—"W. B." (p. 307) may take it, as a general rule, that all common metals are injurious to plants, more especially copper, which is more easily dissolved than any other, particularly if the juices of the plant are at all acid. To make assurance doubly sure, metal labels should be attached to plants by well-waxed threads.—W. W.]

Ants.—Of late my plants have been infested with ants. I have tried to exterminate them by placing pieces of camphor in their runs and a weak solution of paraffin oil, but without success.—T. M. M. [Try the effect of sprinkling fresh guano on the places which they most frequent.]

Camellia Flowers.—I have no information "J. B." that I have a cherry-red self-coloured sport of *Lavania Maggi Camellia*. I did not notice it before this year.—A. MARTIN, *Cork.*

Names of Plants.—R. GILL.—A very bold and richly-coloured *Rhododendron*. We should advise your sending it to some of the Surrey growers and having it tried further north than your own district. *A. L.*—Some *Epidendrum*, but what species the specimen sent does not enable us to say. *J. H.*—*Gentiana aspera*. *J. W.*—We do not recognise the leaves alone; send us fresh specimens when in flower. *A. B.*—1, *Saxifraga crassifolia*; 2, Double *Primrose* (*Primula acutis*); 3, *Polyanthus* variety (*Primula elatior*); 4, *Anemone penicillata*; 5, *Chrysanthemum coronarium*; 6, *Phlox serratifolia*. *O. L.*—*Narcissus papyraceus*, var. near *dubius*; 2, *Narcissus moschatos*; 3, too much decayed to determine rightly, but either *moschatos* or *cernuus*; 4, *N. pseudo-narcissus* var.; the scrap of *Sedum-like* plant is *Rhodola rosea*. *X. M.*—Star of Bethlehem (*Ornithogalum arabicum*) (*Axon*). We do not recognise any of the leaves of tropical plants sent, and we doubt whether any botanist would like to be responsible for naming plants from leaves only. *J. H. F.*—1, *Salicigna stolonifera*; 2, *Mertensia*; 3, *caesia*; 4, *Wildenovi*.

Names of Fruits.—J. M. R.—*Ne Plus Meuris*.

Prickly Comfrey.—Messrs. Carter & Co., High Holborn, will furnish you with plants of this, but probably not seed; they may be planted now.

Questions.

Cyclamen Sports.—Amongst seedlings of *Cyclamen persicum* I have one plant with seven large, finely-shaped blooms. The first that opened is a beautiful pink with a dark crimson eye; the other six are all pure white, without the least trace of colour about them. That they all spring from one bulb is certain, as the bulb is slightly above the soil in the pot and can be distinctly seen. Is this unusual? It is considered here to be quite a curiosity.—H. HARRIS, *Denne Park.*

Bean Disease in the Ionian Islands.—Having recently taken a farm here, my first crop of Broad Beans has shown a disease called here the wolf; a miniature tuberculous excrescence forms on the root of the Bean stock (when about flowering), giving out a thick as my forefinger, and making the flowers and leaves like a Hyacinth. It takes all suction from the Bean stock, which gradually turns black and dies. Can any of your readers suggest a remedy?—FRED. C. BROWN, *Cork.*

Seedling Cinerarias.—Having this season some very fine *Cinerarias*, I send half-a-dozen seeds. I raise them from seed, and have about ten dozen, all equal to those sent, at present in the conservatory; their heads measure from 18 in. to 24 in. across.—A. KAYAK, *Highgate, Middlesex, and Waltham Cross, Essex.* [The blooms sent were large, bright in colour, and good both as regards substance and form.]

Rhododendron Blooms on Old Buds.—In lifting *Rhododendrons* for forcing lately we found one with good plump flower buds, surrounded by the seed-pods from last year's flowers. I do not remember having observed the same thing before, but possibly some of your correspondents may have done so. Some plants, such as *Phalaenopsis amabilis* will flower several times from the same spike, and *Hoya carnosa* from the old flower-stalk, but I was not before aware of *Rhododendrons* having the same propensity.—J. GROOM.

lanceolate glaucous leaves, and terminated by dark-blue flowers, arranged in dense spikes of nearly 1 ft. in length. Of this fine species a characteristic coloured plate was given in THE GARDEN (Vol. X., p. 548). Mr. Green informs us that the plant as exhibited was raised from seed two years ago, and wintered in a greenhouse. The plants are also said to enjoy the hottest of sunny positions out-of-doors during the summer months, so as to thoroughly ripen their wood for flowering. Among the plants honoured with first-class certificates on this occasion were *Gloxinia* Mrs. Bause, a large and showy white flowered kind, having a ring of rosy crimson around the throat of the corolla, and the White Lilac (*Syringa alba-grandiflora*) previously alluded to. The show was conveniently and tastefully arranged, and the Azaleas and other decorative plants from the Society's garden, as usual, excellent.

NATIONAL AURICULA SOCIETY.

APRIL 22.

THE southern section of this Society was held, on this occasion, in connection with the Fruit and Floral Committee Meeting of the Royal Horticultural Society, at South Kensington. There were exhibitors from as far north as Yorkshire, but the season has been most unpropitious, and the flowers have been rather unduly forced to get them in flower at the date required. The competition for twelve show varieties was restricted to four exhibitors, the first position being taken by the Rev. F. D. Horner, Kirby Malzeard; Mr. Horner also gained the highest prizes in many of the other classes. Mr. Douglas, gardener to Francis Whitbourn, Esq., gained the highest award in the class for fifty plants, including Alpines, although exhibitors will not include Alpines in such a class if they can help it. Mr. Douglas also exhibited the best Polyanthus of the gold-laced section, the best border Polyanthus being sent by Mr. R. Dean, Ealing. Alpine Auriculas were very pretty indeed, and much more hardy than the show flowers; they will stand out well in the open borders during the severest winters. The best were sent by Mr. Charles Turner, of Slough; two of his new ones, Duchess of Connaught and A. F. Barron, received first-class certificates; they were both of a very refined character, and the edges were beautifully shaded, one of the first properties of an Alpine. The Rev. F. D. Horner exhibited some very choice seedlings, notably a dark self named Ringdove, in which the paste is dense, pure white, and quite circular; Grey Friar, a large grey-edged flower, sent by J. T. D. Llewellyn, Esq., Ynisgyrwn, Neath, also received the Society's highest award. It is noteworthy that, notwithstanding the great efforts being made at present to raise seedlings, the old flowers sent out nearly fifty years ago are still superior to any of them. George Lightbody, Headly, received the prize offered for the best Auricula in the exhibition, certainly a very old flower raised by the late veteran grower of Stapleford. The following were the best flowers exhibited in the different classes; viz., Show Auriculas, green edges, Freedom, Booth; Colonel Taylor, Lee; Admiral Napier, Campbell; Prince of Greens, Trail; Champion, Page; Lovely Ann, Oliver. Grey edges—George Lightbody, Headly; Lancashire Hero, Lancashire; Complete, Sykes; Alexander Meiklejohn, Ray; Charles E. Brown, Headly; Colonel Champney, Turner. White edges comprised—John Simonite, Walker; Smiling Beauty, Heap; Glory, Taylor; Earl Grosvenor, Lee; Ann Smith, Smith; Catherine, Summerscales. Selfs comprised as the best—Pizarro, Campbell; Topsy, Ray; Lord Lorne, Campbell; Charles J. Perry, Turner; Metropolitan, Spalding; Eliza, Sims. A few of the best Alpines exhibited were Beatrice, Turner; Susie Matthews, Turner; Mrs. Ball, Turner; Unique, Turner; Sensation, Turner; Mrs. Meiklejohn, Meiklejohn; Diadem, Gorton; Florence, Douglas. The best Polyanthus were—George the Fourth, Exile, Rev. F. D. Horner, Beauty of England, Cheshire Favourite, Lancer, and William the Fourth. Supplementary to the Auriculas and Polyanthus were the usual goodly display of Roses in pots; and also in a cut state Orchids, &c., the whole making a very good exhibition.

ROYAL BOTANIC SOCIETY.

APRIL 23.

A VERY effective display of spring flowers formed the leading feature at this meeting, comprising well-staged collections of Auriculas, Cinerarias, Roses, Cyclamens, Amaryllis, Azaleas, &c., amongst which were numerous examples of high class cultivation.

Botanical Certificates were awarded to the following:—

Odontoglossum odoratum (Veitch & Son).—A new species, much in the way of *O. gloriosum*, but with small blossoms, which exhale a delicious odour.

O. Ruckerianum (Veitch & Son).—A beautiful kind, similar to *O. Alexandræ*.

Dendrobium nobile atro-purpureum (Bull).—A new variety, with larger and more richer-coloured blossoms than the original.

Phaius Blumei (Bull).—A species with large flowers, the sepals of which are buff and the lip white.

Sarcocochilus Fitzgeraldi (Veitch & Son).—A dwarf, neat growing species, with an *Aerides*-like habit and rather small flowers: white speckled with purplish-violet and yellow centre.

Oncidium Kienastianum (Veitch & Son).—A new, but not a very ornamental species, similar to *O. crispum*.

Phalenopsis Parishii (Veitch & Son).—A curious little novelty, with small blossoms, creamy-white tipped with dull purple.

Kentia MacArthurii (Veitch & Son).—An elegant new Palm, with gracefully-arching foliage.

Geonoma concinna (Bull).—A distinct new Palm, of elegant growth.

Kentia Wendlandiana (Bull).—A new species, with pinnate foliage and good habit.

Cataglyphis Hopei (Williams).—An interesting new Cycad, with elegant pinnate leaves of leathery texture.

Coleus Surprise (Bull).—A pretty variety, with green leaves mottled with creamy-white.

C. Distinction (Bull).—Another ornamental kind, with foliage of a vinous-metallic hue, forming a striking contrast to the last.

Amaryllis Hercules (Little).—Flowers of good form of a fiery scarlet colour.

Auricula Grey Friar (Llewellyn).

A. Unique (Turner).

A. Susie Matthews (Turner).

A. Duchess of Connaught (Turner).

Tulipa Greigi.—This handsome Tulip was shown in a rather poor condition, which failed to exhibit its high-class merit (see THE GARDEN, plate LXIII.).

Primula polypetala flore-plena (Paul and Son).—A charming double Primrose, with flowers of a rich deep purple.

Floricultural Certificates were awarded to—

Azalea Marvel (Bull).—An excellent novelty, very floriferous, though the blossoms are somewhat small, with a tendency to become double. The colour is a rich purplish-rose tint.

A. balsamiflora (Bull).—Another fine variety of real merit, with perfectly double flowers of a rich salmon colour.

A. William Carmichael (Williams).—A kind with rather small flowers of brilliant colour.

Stove and Greenhouse Plants.—The first prize was awarded to Mr. G. Wheeler, gardener to Lady Louisa Goldsmid, Regent's Park, the only exhibitor in the class who staged fair-sized and well-flowered specimens. Six greenhouse Azaleas came from Mr. A. Ratty, gardener to R. Thornton, Esq., the Hoo, Sydenham; a good but inferior half-dozen to the last came from Mr. James, gardener to W. F. Watson, Esq., Isleworth; Mr. Charles Turner also staged excellent medium-sized plants. The class for nine Cinerarias was well contested, and excellent examples of good cultivation were shown by Mr. James, Mr. J. Wiggins, gardener to H. Little, Esq., Uxbridge, and Mr. G. Brightwen, gardener to Lady Clare, Great Stanmore. Messrs. Carter & Co., High Holborn, also exhibited numerous examples of a brilliant strain, remarkable for rich variety in colour and form. Mr. Wiggins showed *Amaryllis*es, the finest being *Hercules*, *Hereward*, and *Morning Star*; Mr. B. S. Williams also showed in this class. Auriculas were shown in excellent condition; Mr. C. Turner took the first prize for twelve; 2nd, Mr. Llewellyn, whose certificated variety, *Grey Friar*, was very beautiful; Mr. James also exhibited in this class.

The Miscellaneous Class for extra prizes was very numerous, including a good display of rare and new plants from Mr. Bull, several of which obtained certificates. Messrs. Veitch & Son also staged a fine bank consisting chiefly of Orchids, the majority of which were new and certificated; a very fine lot of Orchids were shown also by Mr. Heims, gardener to F. A. Philbrick, Esq., Regent's Park. An excellent group of fine-foliaged plants and Orchids also came from Mr. B. S. Williams. Messrs. Paul & Son, of Cheshunt, made an excellent display with well-bloomed Roses in pots, which were much admired, as were also some cut blooms shown by the same exhibitors. *Pelargoniums*, *Cyclamens*, and *Hyacinths* were also shown in good condition, and greatly added to the attractiveness of the meeting.

No. 289.]

Vol. XV.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SITUATIONS FOR SPRING FLOWERS.

EVERYONE who has a garden wishes to see it brightened up early in the year with flowering plants. The advent of the Snowdrop is hailed with delight, and as the season advances the Daffodil, the Crocus, and the Primrose receive each in their turn a hearty welcome. Spring flowers come as old friends, and, unlike many kinds of plants with which we adorn our parterres in summer, they remain with us the whole year through; and if we cherish them they reward our care by an annual renewal of their pretty flowers. Most of us may have at some time or other visited one of those old-fashioned gardens, now, unhappily, becoming more and more rare, in which dense masses of Daffodils, Anemones, Tulips, and glorious bunches of brightly-coloured Primroses and Polyanthuses were to be found growing in wild luxuriance. How finely they grow and bloom under the shelter of old fruit trees, and we may be told that this patch of Narcissi has all sprung from a single bulb planted years ago, and that that mass of Violets or group of Primroses has annually flowered in that same place for a long period. Loving these bright heralds of spring as we do, and anxious as we are to have them amongst us, is it not strange that we do not, as a rule, make better provision for them? Their requirements are small, but they are grateful for even a little care. When placed in hot, dry situations, they cannot exist any number of years in good condition. Where, for instance, do we find the Primrose growing naturally? in sheltered, semi-shady nooks, in woods, in the hedgerows, in well-drained but fairly moist soil. If we wish to make this charming race of plants feel at home with us, we must accord them these conditions. We must take the old-fashioned garden for our model, and we shall doubtless find that there are some spots in our gardens, modernised as they may be to suit the present fashionable style of gardening, which will pretty well reproduce the conditions in which we know that these spring flowers grow so well, live so long, and flower so freely. We have no need to go farther than the so-called shrubbery to find suitable situations for most of our spring flowering plants. When shrubberies are planted, they might be so arranged as to secure plenty of verdure, and at the same time cosy little sheltered nooks might be created, where the Primrose, the Snowdrop, the Cyclamen and many more of our little floral gems might nestle undisturbed by the spade or other garden implement, and where with but little care they would yearly increase in size and blooming capacity. Shrubberies thus arranged would be a source of much interest; the Laburnum, the Lilac, the Laurel, and even Conifers might be made to shelter Violets, Primroses, and similar plants, which would be most grateful for their friendly protection.

Spring flowers, to give satisfaction, should be planted where the soil around them is but little disturbed; they should be seen in masses. A single Snowdrop or Narcissus gives no idea of the real beauty of either of these plants; it is only when thoroughly established and growing and flowering with native vigour that a just conception of their merits can be formed. In many establishments the whole of the flower beds are devoted to summer bedding; it is, therefore, useless to attempt the permanent culture of spring flowers in them. They must either be removed at a considerable amount of labour to suitable summer quarters, or they become stifled and dried up amongst other plants. In large establishments there are always situations adapted for a wild garden, where every condition necessary for successful plant growth may be realised, but many gardens do not possess sufficient scope for this purpose, and then shrubby borders will be found to be serviceable. A too prevalent custom in this country consists in forming continuous lines of trees and shrubs, which are often so arranged as to present a very uniform, and oftentimes where large quantities of common Laurels and Rhododendrons are planted, an almost unbroken surface. These compact masses of trees and shrubs are scarcely more attractive or offer greater variety than a closely-clipped evergreen hedge would afford. If, instead of this close, formal arrangement, the outline were broken up here and there, forming little recesses, and carrying up the turf at intervals somewhat irregularly between and amongst the shrubs, which would, in any case, be preferable to the formal Grass edgings so often seen, some of the prettiest effects of spring gardening might be carried out. In the little recesses and sheltered spots thus formed, the shade, the shelter, the undisturbed repose, which are indispensable to the well-being of so many of our low-growing, flowering plants, might easily

be accorded them. There, too, every aspect would be obtainable and each individual species and variety would get the position most suitable for it.

How often do we hear the complaint made that so many of our beautiful varieties of Primroses fail to thrive. There is really no reason why, in our climate, they should not succeed; they only need to be placed in natural situations, and they would undoubtedly flourish and yearly increase in vigour. Illustrations have been given in THE GARDEN at various times of groups of Cyclamens, Snowdrops, Hepaticas, &c., in which the results of the judicious selection of natural situations were admirably portrayed. Not only when thus placed do they thrive better, but the arrangement gratifies the eye. One sees at a glance that the surroundings are in accordance with Nature's teachings. We can never err by endeavouring to introduce variety into our gardens, and it is surprising how much may be accomplished, even in small places, to vary their aspect. In the distribution of spring-flowering plants much may be done in this way. There might, for instance, be one nook devoted to the various kinds of Narcissus, in another we could establish Snowdrops and Crocuses, another recess might contain a collection of Primroses, and so on, and during the summer we would have the satisfaction of knowing that they would never be in any way molested, and in the early days of spring we could, as in old-fashioned gardens, wander from spot to spot and welcome our old friends as they appeared.

J. CORNHILL.

Early Violas.—The hardy bedding Pansies which have of recent years been produced—the result of crossing *Viola cornuta* and *lutea*—have proved to be amongst the most satisfactory of spring bedding or border plants. Those that have stood all the winter in the open ground are now fast becoming fine clumps of bloom, and those with mixed Polyanthuses and patches of Aubrietias are the most effective of hardy garden plants this spring. Some kinds of these bedding Violas still hold their position as the best of their respective colours, a few others have had to give place to improved kinds, but new sorts have been sparse of late, as it is difficult to improve where there is so little room for improvement. Of white kinds, the purest and earliest is now a sort named Profusion, sent out from Edinburgh, but of summer-blooming kinds the best is Vestal, a southern production; these two excel all others for bedding purposes, and where they are grown none others are needed. Of yellow kinds, the very earliest, and therefore the most useful in the spring garden, is Yellow Boy; it is dwarf, bright in colour, and remarkably free. Bedfont Yellow is another good early variety, and for summer use the best are the old Cliveden Yellow and the paler yellow, Crown Jewel. Blue shades of colour are more abundant. Of these the best are Blue Beauty, a deeply coloured kind; Blue King, royal blue, a charming, delicate, marine blue; the TORY, a deep purplish-blue; Blue Beard, a very rich indigo-blue, dwarf, free, and continuous as regards flowering; and Improved Blue Bell, a most floriferous kind. In the purple section, the old Cliveden Purple is still one of the best for spring, although none of this colour are very early; Mulberry is the handsomest for summer use. Of other kinds, lilacina and rubra lilacina are charming mauve kinds; Harlequin is a pretty tricolor flaked variety; and Peach Blossom is a good reddish-lilac.—A. D.

Shaded Self Polyanthuses.—A race of hardy Polyanthuses is springing up that will, it is hoped, possess many of the beauties of the shaded Auricula. The flowers are of medium size, good in form, flat, and have a distinct lemon centre, margined by a dark shaded colour; they seem almost duplicates of the shaded Auricula. Plants belonging to this strain differ in all respects from those that are gold-laced, as far as the flowers are concerned, but they resemble them in habit, flowering about the same time. They differ, however, entirely from the fancy or border section, amongst which are some useful sorts, such as white, yellow, red, purple and crimson selfs, and many flowers with varied hues and markings. In the introduction of new strains of flowers of this description, a special impetus must of necessity be given to the cultivation of the Polyanthus, both for ordinary garden purposes and also for exhibition. Many consider that the very refined gold-laced flowers lack variety; the best kinds, also, are difficult to cultivate, and seedlings from them are seldom good, whereas good fancy or shaded strains will invariably reproduce some as good as the parent, and a few, perhaps, better.—A. D.

Sweet Williams after the Frost.—The winter, severe as it undoubtedly has been, has left these quite uninjured; their foliage is fresh and green, and the plants vigorous, showing no evidence of damp or decay. This fact is worthy of being noted, when Stocks, Wallflowers, Antirrhinums, Pentstemons, and other biennials have been killed wholesale. Those who may desire to secure a good display of Sweet Williams next year should at once procure seed and sow it, as it is well to have the plants strong and capable of

producing several heads of flowers at blooming time. Such plants will be secured if seeds be sown at once. The strains known as Hunt's and the Auricula-eyed are both good, and produce huge heads of flower, whilst their markings are varied and beautiful. The finest effect is obtained when they are grown in masses, as the flower-stems not only serve to support one another, thus obviating tying, but also show off the beauties of the bloom to better advantage. The Sweet William is at its best about midsummer, and continues in bloom all the month of June.—A. D.

Violet Culture at Laxenburg.—We have Violets in flower here from November until March. In order to have good established plants before autumn sets in we plant out in May in a bed composed of rather sandy, rich garden soil. The plants used consist either of cuttings, which have been struck in spring, or one-year-old plants which have been kept in pots to flower throughout the winter. After planting out care is taken to keep the soil well stirred, and to peg down any runners that are formed during summer. Occasionally a top-dressing of leaf-mould is given to encourage a strong free growth. At one time we used to shade our plants during the hottest summer months with lattice work, but now we have done away with that, and sow broadcast amongst the plants some seed of the common Dill (*Anethum graveolens*). When up these are thinned, leaving just sufficient to give a slight shade to the Violets. Thus fortified, our beds are exposed to full sunshine, and the plants are undisturbed until they have done flowering, but in November when the blooms begin to appear frames are put over them to keep them from frost. Well-established plants flower, as I have said, continuously from November until March, but a great deal, nevertheless, depends on the weather. During a few hours of sunshine flowers increase rapidly, both in size and numbers. Our plants are only allowed to flower one year; after that they are removed, the best runners are selected for cuttings and put in at once, four in a pot; they are then kept cool and shaded in a frame until they strike root. Generally half of the cuttings thus struck are planted out the same year in May; the other half are shifted into larger pots, in which they are wintered. Generally speaking, however, one set of plants is about as good as the other by the autumn. The Czar is the only variety which we grow.—LOUIS KROPATSKY.

Spring Flowers in Yorkshire.—After so severe a winter as that just experienced, it is most interesting to me to read what is in bloom early in April in open borders; therefore, one, the sake and give principle, allow me to tell others that I have the following in bloom here to-day (April 10): viz.: *Anemone nemorosa* f.-pl., *Sanguinaria canadensis*, *Pulmonaria officinalis*, *Scilla taurica*, *S. bifolia*, *S. sibirica*, various kinds of *Hepaticas* (including *angulosa* and the double blue), the *Marguerite Daisy* (cold frame), *Primula denticulata*, *P. pulcherrima*, *Sisyrinchium grandiflorum*, *Hyacinths*, double and single *Primroses* (florists' kinds), *Omphalodes verna*, *Androsace carnea*, *Iris reticulata*, *Auriculas* (Alpine and florists' kinds), *Vincas*, *Draba azoides*, *Chrysosplenium oppositifolium*, *Daphne Cneorum*, *Erica carnea*, *Auricula alpina marginata*, *Jessamine* (double yellow and *J. nudiflorum*), *Hellebores*, *Saxifraga Burseriana*, and, besides these, I scarcely need name the various kinds of *Crocuses*, *Narcissi*, *Arabis*, *Aubrietia*, *Pansy*, *Tussilago*, *Polyanthus*, *Violets*, *Daisies*, and last, but far from least, *Wallflowers*.—J. WOOD, *Woodville, Kirkstall*.

Crown Imperials.—What noble spring-flowering bulbous plants these are! I have groups of them in the borders in front of my house 3 ft. high, each stem carrying whorls of beautiful large drooping flowers surmounted by a crown of lance-shaped leaves, which seem to add to the effectiveness of the flowers. Many of the stems bear six flowers in the whorl, thus showing their strength, as weakly bulbs have only five or, in some cases, only four. Like most spring flowers, they are later in blooming this year than usual. In mild seasons they often flower in March. All the *Fritillarias* are beautiful, and very easily cultivated. Like most of the *Liliaceous* plants, they flower best when not often disturbed, or if taken up, they should not remain long out of the ground. They are not particular as to soil, but a light deep loam suits them best. What manure is used should be well decomposed.—E. HOBDAK.

Myosotis dissitiflora.—Allow me to inform Mr. Legge (p. 318) that in reality this plant is best treated as a biennial; the seeds should be sown one year to produce flowers the next. Of equal quantities of plants raised from seed and from cuttings, all of the former will live, whilst perchance one half of the latter will die during the winter. It is because of this inevitable fatality that failures so often result to old or propagated plants. If it be desired to propagate by means of cuttings, pull away every available shoot in September, and dibble them out thickly in a piece of ground; each one will make a well-rooted plant in a few weeks.—A. D.

—The difficulties under which your various correspondents appear to labour in growing this most useful *Forget-me-not* are to me inexplicable, for with me it thrives without the slightest

trouble. About five years since I purchased a dozen plants of it for a border, and ever since I have had an abundant supply of self-sown plants of it, besides yearly giving large quantities of it to my friends. With me it is perfectly hardy, and after the severe winter which we have had, the young plants are, if possible, more healthy than usual. I have some single plants of it quite 6 in. across both ways. The border in which they have all along been is in front of a house facing the south, and they are exposed to the full blaze of the sun in summer and to the east winds in spring.—F. J. ALEXANDER, *Fernlee, Gunnersbury*.

Cliveden Blue Pansy.—Amongst the few spring flowers that have maintained their usual character for early flowering must be mentioned this beautiful Blue Pansy. We have many large vases edged with it, and the fine effect which it produces is heightened, as it were, by the dreary weather and general backwardness, or rather absence, of spring flowers, which prevails this season. This variety, so lovely in spring, loses its colour under bright summer sunshine and becomes a pale grey, but for spring gardening it is still unrivalled.—J. GROOM, *Linton Park, Maidstone*.

Fuchsias.—Everything possible must now be done to get spring-struck Fuchsias large in size. A little shade should be given them when the sun is bright to encourage growth and sufficient pot room, syringing freely overhead every day, picking off the flowers and stopping the principal shoots, so as to furnish plenty of branches.—T. BAINES.

LAWNS, CROQUET AND CRICKET GROUNDS.

MESSRS. SUTTON & SONS, of Reading, have published, in the form of a circular, the following hints on the laying down and improvement of lawns, &c.: A good close velvety turf is one of the most ornamental objects a garden can boast of, and oftentimes the most difficult to obtain. In the first place, careful preparation of the ground proposed to be laid down to turf is necessary. This should be commenced in the winter by draining, if found requisite, and digging to the depth of 6 in. to 12 in., according to the nature of the soil. The land should then be levelled and made firm with a heavy iron roller, and subsequently raked, to remove stones, &c. Where the natural soil is too stony, a supply of good mould should be spread over it, to the depth of 2 in. or 3 in. If the land is poor, some well-rotted stable-manure will be very beneficial; but where this cannot be obtained the best dressing of artificial manure is 2 cwt. of superphosphate, 2 cwt. of Peruvian guano, and 2 cwt. of dissolved bones, mixed, per acre. In March, after the ground has been made thoroughly fine and clean, a heavy iron roller should again be used to make it perfectly level, and as the subsequent appearance of the lawn depends in a great measure on this part of the preparation, we cannot too strongly urge the importance of its being well done. The ground should then be evenly raked, the seed sown, at the rate of 3 bushels per acre, and the ground lightly covered with fine mould. April and September are the best months for sowing. After this has been accomplished, the ground should be again rolled, and as soon as the young plants have attained the height of 2 in. or 3 in., the whole plot should be carefully gone over with a sharp scythe, and from the months of April to October should be mown every ten days. Frequent mowing and rolling are indispensable to maintain the turf in good order. A close green sward will thus be obtained in nearly as short a time as a lawn produced by turves, while it will be far more permanent, and at much less expense. Ransome's mowing machines are excellent after a comparatively close turf is established; but for the first six months after sowing, we recommend the scythe to be used in preference to the machine. It will sometimes happen that annual weeds indigenous to the soil come up; these can easily be checked, if not destroyed, by mowing them off as soon as they make their appearance. Plantain, Dandelions, and Daisies, too, will often appear, and these must be cut up each one singly about an inch below the surface (not deeper), and about a tea-spoonful of salt dropped over the cut part. Birds are very fond of Grass seeds, and care should be taken to keep them off until the seeds are well up. It often happens that lawns subject to constant use become thin as the autumn approaches. To improve them is easy and inexpensive. In September or March lightly rake the turf, sow some of our fine Grasses and Clovers, at the rate of 20 lb. per acre, apply a thin dressing of mould mixed with some well-rotted manure, or dissolved bones, and well roll afterwards. Moss in lawns is generally a sign of poorness in the soil, or a want of drainage. To effect its removal, rake off as much Moss as possible, apply a top-dressing of quick-lime mixed with rich compost in the winter, and sow more seed in the spring; or a top-dressing of soot will, by encouraging the growth of Grass, destroy the Moss. This should be applied in the spring, at the rate of about 16 bushels per acre. Croquet or cricket grounds, where the turf has become bare through constant use, may be quickly improved and made ready for the next season's use, by sowing seeds

thickly on the bare places during September or March, according to the instructions given above. Whether the turf is bare or not, it will be found generally beneficial to apply during the winter a slight dressing of either well-rotted stable manure, or the mixture of artificial manure before mentioned, at the rate of 2 cwt. per acre, which will greatly encourage the growth of finer kinds of Grasses, and help to produce a close-growing turf. We should not omit to mention here, as in fine garden lawns, that mowing alone will not insure a good bottom, without that compression which a roller alone can give.

PRIMULA GRANDIS.

A VERY distinct Primrose; native of the Western Caucasus, at an elevation of 6000 ft. to 9500 ft. It was described some years ago by Trautvetter from an imperfect dried specimen preserved in the Petersburg Herbarium. Boissier has taken it up in his "Flora Orientalis," with the remark "*Species pulchra ulterius inquirenda angustie laciniarum corollæ insignis*." It now appears to have been introduced into Russian gardens, and a figure of it was recently published in Regel's

Primula grandis.

"Gartenflora." This Primrose is remarkable for the narrow, erect lobes of its rosy corolla. The accompanying engraving was prepared from the figure in the "Gartenflora," from which some particulars respecting the plant may be extracted on a future occasion. There are no dried specimens of it at Kew. W. B. HEMSLEY.

DOUBLE-FLOWERED DAFFODIL.

WE have sent you a couple of flowers of a double Narcissus for inspection; we believe it to be a variety of the common double yellow Daffodil Van Sion, and have named it *Ajax major albus variegatus fl.-pl.* We suppose it to be new; at least we never saw it before. Perhaps you will be kind enough to give us some information respecting it.

A. E. BARNAART & Co., *Bogelenzang*.

[The double-flowered Daffodil sent is very beautiful, and although grown in English gardens many years ago, it is now comparatively rare. A characteristic coloured figure of it is given on plate 44 of Hale's "Eden," a fine old work on garden flowers, published a little over a century ago. The variety is there called the Silver and Gold Daffodil, which is a most expressive name, and at p. 517 we are told that "the petals are of a very delicate shining silvery-grey and the cup yellow. This is the

natural colouring, but sometimes the yellow runs in light variegations among the grey, and often the grey in the same manner spreads itself among the yellow; either way, the colouring is extremely singular as well as pretty." As a variety, it is quite distinct, and it is so rare in our gardens that, for trade purposes, it is, to all intents and purposes, a "new" plant. It is a double variety, nearly as large as the common double yellow (*N. Telemonium plenius* of Herbert), but the perianth segments are of a delicate sulphur colour—indeed, nearly white, so that the contrast between them and the rich golden coronal segments is very striking. It is not of the Spanish or *N. major* race, nor of the race of *N. Telemonium plenius* or Van Sion of Dutch gardens; it is simply a double form of one of the large wild Daffodils (*N. Pseudo-Narcissus*), near *N. bicolor*, having whitish perianth segments. We are glad to see that so interesting a variety is yet preserved to cultivation, and should be obliged for particulars of it, so far as may be known to our correspondent. The common name, "Double Silver and Gold Daffodil," would be the best one for it; if, however, a Latin one must be had, then we may recommend *N. Pseudo-Narcissus variegatus plenius*, or *N. Pseudo-Narcissus alboluteus plenius*, as being a more correct one than that suggested, which would prove misleading to English cultivators of these favourite flowers.—B.]

THE FRUIT GARDEN.

ORANGE CULTURE AT WENTWORTH.

SOME forty years ago our Orange trees used to be taken to the south front of the castle during the summer months, and were placed during winter in a dark room with only four windows in front to give light; there were then only a few leaves on one side of the trees; at that time the slated roof was taken off, and a glass span-roof substituted. This increase of light caused a slight improvement in the trees. Still, their exposure during the summer, and the cold temperature of the Orangery, where the fire heat was barely sufficient to keep out frost during winter, told detrimentally on the health of the trees; they made weakly growth, and bore a few small Oranges. Seven years ago a large conservatory was built, into which we took the better half of our trees, keeping the remainder in the Orangery, and had it furnished with hot water, so that we could give more heat. The extra warmth which we now give has made a wonderful improvement on the trees, both as regards fruit and foliage. They now bear good-sized fruit, are clothed with healthy leaves, and it is delightful to enter the Orangery when the blossoms are opening early in spring. We give them copious syringings daily during the growing season, and use a compost consisting of fibry loam, charcoal, spent Hops, sand, and a few bones, if at hand. The trees are in tubs, and remain for a number of years after being shifted undisturbed. We give them a night temperature of from 55° to 60° in winter, and about from 60° to 65° in summer, with a proportionate rise in the daytime, according to the state of the weather. The Seville Orange is the kind which we mostly grow, on account of its habit being more graceful than that of the others, and we find that the fruit hangs longer on the trees, on which there is now a fine crop of Oranges, which have been fully ripe six months, and yet look plump and bright. I consider Orange trees to be very desirable subjects for conservatory decoration, and very interesting at all periods of the year, often having ripe and green fruit and blossoms all on them at the same time; in fact, I know of no other plants which elicit so much admiration from all who see them.

I find Oranges very useful in the dull months of winter, when there is not much variety amongst dessert fruits. At that time a good dish of home-grown Oranges, with a portion of the branch on which they grow and leaves attached, is very desirable.

JAMES BATTIE.

[Some specimens of Mr. Battie's Oranges accompanied this communication and were, in all respects, excellent.]

GRAPES FROM VINES RAISED FROM EYES THE SAME YEAR.

I SEE that Mr. Groom doubts my statement under this head (p. 335), and adds that the plan "is certainly something new in Grape culture." I am pleased to be able to answer his questions, and to tell him, however, that the plan is not new, and this was the reason why I did not enter into particulars before. The subject was thoroughly ventilated in the horticultural papers a number of years ago, and has often been alluded to since in THE GARDEN and elsewhere. The plan, which Mr. Groom will perceive, at once disposes of his theory that Vines require a distinct period of rest previous to fruiting under all circumstances, is simply as follows:—Strike the Vines from eyes in March, and grow them on in the usual way till the canes begin to change from green to yellow and the eyes get plump, and at this

stage, but not later, cut off all the leaves and laterals and at once start the Vines in a moist heat, which will cause the permanent buds to break, which would otherwise have remained dormant till another year. This will be about August, and the fruits will be ripe somewhere about the new year, according to the speed at which they have been pushed on. I have often caused the joints of young planted-out canes to break in this way, just by way of experiment, but never forced a regular crop, for the reason that we have always had plenty of good Grapes from midwinter onwards. I, however, once saw a house of pot Vines just starting in this way for a regular crop at Thoresby Park, and Mr. Henderson expected a good crop from them, and they certainly looked as promising as any Vines which I ever saw. The practice is founded upon the fact that Vines, often by too close pinching, break their permanent buds on the current year's canes and ripen a second crop; indeed, it is seldom odd bunches accidentally produced in this manner are not to be found in Vineries, and probably Mr. Groom has observed as much himself without the idea occurring to him that this disposition of the Vine might be taken advantage of under certain circumstances, as has been described. I may add that I did not expect any one to "question the capability of young rods to finish off a good crop the second year of their existence," because the practice is common, but I have not yet heard of any one who has made a practice of leaving their Vines 18 ft. or 20 ft. long the first season and fruiting them the whole length of the rather the second or even the third year, and going on in a regular way afterwards. J. S. W.

STRAWBERRIES ROOTING THROUGH POTS.

ALLOW me to inform "J. S. W." (p. 326) that I did not assert that the rooting through the pots exercised a detrimental influence upon the flowering and the setting of the fruits. What I did say, and what I would repeat, is, that when the plants root through their pots, before the flower-truss is thrown up, it is apt to cause an unnecessary luxuriance of foliage; whereas, if the roots only enter the fresh soil when the flowers are opening, the fruit gets the full benefit of the extra nutriment, and swells up much finer than it otherwise would do. The conclusions at which I have arrived upon this subject are not deduced from theory, but are the results of actual practice extending over a period of years. "J. S. W." will find that in my previous remarks I did not entirely condemn his practice, having myself grown very fair crops on the rooting-through system, but repeated trials have convinced me that better fruit and more of it can be obtained when the roots remain in the pot. By confining the roots to the pot we preserve a complete command over them, and by placing them in pans they can be supplied with an unlimited amount of manure water when swelling off, the saucers often being filled two and three times a day. I would ask your correspondent why he considers it necessary to employ manure water of an offensive character? If he would put a piece of guano in his tanks, or would use soot-water, his houses would be free from nauseous smells, and he would find these stimulants sufficiently efficacious for his purpose; nor do they, if used in a clear state, soil either the foliage or the fruit. If your correspondent were growing for profit and could compare the two systems over a period of years, he would, I am assured, find, as I have done, that the rooting through the pots is of no real service, and that good fruit is more easily obtainable when the roots are confined to the pot. As bearing upon this subject, I may mention that we grow a considerable number of Strawberries here planted out in cold frames, and we now make a practice of planting in rather poor soil, and mulching when they come into flower. By this means we secure a compact habit of growth, and, being enabled to plant more closely, we get a much larger yield than when the plants are set in rich soil, the quality of the fruit being in both cases equal. Vicomtesse Héricart de Thury is well adapted for private gardens, as it is naturally a heavy cropper; it sets a large quantity of fruit, and is of an exceptionally good constitution. It is, however, of but little use to market growers for general culture under glass. They would be fully too pleased to have their labour facilitated by being enabled to grow such free-growing, robust kinds instead of being obliged to confine themselves, if they desire to make a good price of their fruit, to such varieties as are distinguished by a more delicate constitution. I have been acquainted with several growers who succeeded very well with Héricart de Thury when they failed with other kinds, and it is a variety that I should recommend to those who aim rather at obtaining a fair crop of Strawberries than the production of first-class market fruit. J. CORNHILL.

Byfleet.

Strawberries for Table Decoration.—Strawberry plants^s in fruit are often used for this purpose, though Mr. Groom (p. 355) seems to think they are not. I may mention, however, that indoor

Strawberries, gathered into a sieve and placed in the sun, or near the influence of fire heat, for a certain time, are far more palatable than those which are freshly gathered in a moist house and immediately sent to table.—THOMAS COWBURN, *The Gardens, Sunbury Park.*

Apples Grown for Market in Ireland.—There is no such thing as fruit farming on a large scale in this country such as exists in Kent and other counties of England. The Dublin and other town supplies come from various gardens and small orchards, where there is a surplus after home wants are provided for. It is rather a *mixtrum gætherum* affair, many of the varieties being local, and possessing local names. The varieties, however, which command fairly good prices, and which are favourites with fruiterers are—culinary, Cathead, Echlinville, Kentish Fillbasket, and Yorkshire Greening; dessert, Scarlet Crofton, Irish Peach, Eve Apple, Margil, and Ross Nonpareil.—AMBROSE BALFE, 28, *Westland Row, Dublin.*

Golden Champion Grape near Bristol.—The additional facts furnished by Mr. Baines on this subject (p. 334) are very instructive. Golden Champion Vines started in January with their roots outside in the neighbourhood of Bristol were not in flower at near the end of March, and I venture to guess the bunches of these same Vines are not much more than thinned, if they are that length, at this date (April 26). Now, here, Golden Champion Grapes with their roots all inside were started a month later than those at Bristol, and were equally advanced at the end of March, and the berries on some of the bunches are the size of small Peas; bunches of Hamburgs in the same house are ready to thin. Muscats started early in February are now coming into flower, and a few bunches are set and swelling. The roots are outside principally, and all are under fermenting materials. The Muscat, I may point out, is about a month later than the Champion. It would appear, therefore, that we have saved a month or more in fuel, labour, and attention in our case by treating the roots to the necessary warmth, not to speak of the advantages of the practice in other ways. It is a mistake to transfer the question of protected borders for early Vines to the subject of late Vines that ripen their crop after midsummer, and this is all I wished to point out before.—J. S. W.

FRUIT CULTURE FOR MARKET.

PLUMS.—These are chiefly grown in market gardens in the form of standard and dwarf bushes. Standard Plum trees are planted from 15 ft. to 20 ft. apart each way, unless vegetable crops or bush fruits are not to be grown between them, in which case they are planted more closely. The more room the trees are allowed, however, the more perfectly does the young wood ripen, and heavier crops of better quality are the result. Where vegetable crops are grown between Plum trees it is absolutely necessary, owing to the surface-rooting character of the trees, to deeply dig the ground every year, inasmuch as were this operation neglected one year great danger to the roots would ensue, but when done yearly over-luxuriant growth is prevented by continuous root-pruning, and yet the roots, being small, the trees are not injured by their being cut away, as would be the case if they were allowed to become large before digging between the trees was performed. Annual manuring and deep culture render the trees very productive, and unless the bloom gets injured by spring frosts, thinning of the fruit several times over has to be resorted to, in order to insure a fair crop ripening satisfactorily; after this operation has been performed, no other thinning takes place, and sometimes in good seasons may be observed large trees with their branches supported on wooden props, in consequence of the weight of fruit being more than they could bear without fear of breakage. Princess of Wales, Coe's Golden Drop, Victoria (Blue and Green Gages, Jefferson, Orleans, Kirk's) Washington, Magnum Bonum, Royal Hative and Belle de Septembre, are all kinds extensively grown in the neighbourhood of London. An acre of good Plum trees has sometimes been worth as much as £50, the purchaser being at the expense of gathering the fruit; at other times, however, in consequence of over-abundance of fruit, prices in Covent Garden are remarkably low, common Plums being often sold

for 1s. 6d. per bushel wholesale. Plums are not so much in demand for preserving as some fruit, hence the low prices just referred to; and so imperfect are as yet the means of communication between producer and consumer, that frequently when this kind of fruit is so cheap, it brings so low a price to the grower that it is scarcely worth his while to gather it, and sometimes large quantities are allowed to rot or are given to pigs. The stocks used for Plums are the Brompton or free stock, the Mussel and the Myrobalan. The Prince of Wales Plum is grown by the ton, but heavy losses are often sustained by trees of it dying off. Some attribute this to imperfect union with the stock, others to the soil, and some to the heavy cropping of the trees. The Purple Gage is largely grown on account of its vigorous habit and prolific bearing qualities. It is sometimes called Poupart's Plum; its fruit is about the size of the Green Gage and similar in flavour. Another good culinary plum is Pershore, the fruit of which is yellow, and the trees of it enormous croppers. Belle de Septembre is another favourite Plum, which in some seasons has fetched as much as 26s. per bushel. The Red Compote is a good late kind, which resembles the Victoria, and which in Covent Garden is valued highly, because it comes in late, keeps well, and generally fetches good prices. Well-established trees of it yield enormous crops, even more than the well-known Victoria. Other good standard varieties are Pond's Seedling and Mitchelson Plum, the latter being grown by the acre by some growers. Its fruit, which is excellent for preserving, is of a reddish-purple colour, of medium size, and good flavour. To these many more kinds might be added, but those enumerated are such as are generally grown near London by the best cultivators for market. "Growers in Kent," says Mr. Whitehead in the "Royal Agricultural Society's Journal," "prefer the forward Orleans, Magnum Bonum, Blue Diamond, Victoria Dauphin, Mussel, Early Rivers, and Washington; black Plums sell the best. The trees are planted between Cherry and Apple trees, and are set in plantations by themselves with bushes under them. A tradition exists that £100 per acre has been made in one year on a piece of land planted with Green Gages. The average price of Plums in London is £19 per ton. In 1876 they made from £28 to £32 per ton, in 1871 only from £12 to £14.

There is a famous Damson known in Kent as the Critenden, that has been planted to a large extent during late years. It is propagated by suckers, or "spawn," which come up all round the trees, and yield fruit after their kind without being grafted. After these suckers have been planted out for two or three years, they commence to bear. This kind of Damson is amazingly prolific, and its fruit brings high prices for jam, bottling, Damson cheese, and, as some say, for manufacturing port wine. Plum trees, like Cherry trees, do not require much pruning; on the contrary, they are apt to fall into ill health if the knife be used too freely. It is merely necessary to cut back any over vigorous growths, and to clear out wood that crowds up the centres of the trees. Plum trees do not succeed well in exposed situations, as their roots are so near the surface that they are liable to be blown down by the wind."

Damson trees are now but comparatively little grown in the immediate neighbourhood of London, and as old trees die out young ones are seldom planted in their stead. In Kent, however, they appear to grow wild like the common hedge Bullace, and I have seen the lanes literally overhung with heavy-laden boughs of black fruit. One Kentish grower informed me that if his Damson trees were placed in a line 30 ft. apart, they would occupy a length of twenty-two miles.

FIGS.—These are seldom to be found in the London market gardens, but in the vicinity of Worthing large fields are

entirely devoted to their culture. The trees are chiefly grown in the form of standards, and the soil in which they are planted being of a light clayey character they succeed remarkably well, and in favourable seasons bear heavy crops of fruit. In some Fig orchards there may be counted as many as from 150 to 200 standard trees of great age; indeed, many of them are supposed to have been planted more than 100 years. From each of these trees, in good seasons, are frequently gathered as many as 20 dozen of fine ripe fruit. Fig crops vary very much both in quantity and quality, in accordance with the season, but in hot, dry summers may be seen scores of men, women, and boys busily engaged in gathering the large luscious fruit, and packing them in baskets and boxes ready for Covent Garden Market.

CHERRIES.—These are not very extensively cultivated in what may be termed the metropolitan market gardens. In some places, however, they find a place and succeed tolerably well. The best trees are grown in the form of dwarf, open-hearted standards grafted on the Mahaleb stock within a few inches of the ground, conditions under which they thrive well and bear heavy crops. Vigorous-growing sorts, such as the Bigarreau, are, however, grafted on seedling Cherry stocks. Very little is done in the way of pruning, excepting in the case of dwarf trees, which are kept within bounds by frequently shortening back the young vigorous growth. Tall standards never receive any pruning whatever beyond cutting out old and decayed limbs, the young growth being allowed to grow at random. Knight's Early Black, May Duke, Elton, Late Duke, Kentish and Black Heart are the kinds chiefly grown, although the Bigarreau is by no means neglected where it is found to succeed, and the same remark applies to the Brandy Cherry (the Morello). This, in the form of standards about 6 ft. high, and bearing heads from 6 ft. to 8 ft. in diameter, fruits freely, and in seasons when most other kinds get cut by spring frosts, Morellos grown in this fashion invariably escape. They are grown amongst large Apple or Pear trees, which, to a great extent, protect them. The only pruning they get is removing dead or useless branches.

In Kent Cherries are chiefly grown in Grass orchards, in which the trees are managed on the run-wild system; many of them are very old indeed, and in good seasons they yield heavy crops. When in flower the Kentish Cherry orchards are well worth seeing, covering, as they do, the distant hills for miles round; though in some years the quantity of blossom is unusually great, the crop of fruit may be far below the average. Cherry trees are planted on land overlying a dry subsoil; in clayey soil they are, as a rule, but short-lived. The kinds chiefly grown are the Kentish, Cluster, and Bigarreau; these are good croppers, and from well-established trees have frequently been gathered as much as 1000 lb. of good fruit. In some seasons the Cherry crops are sold by auction, and also by private contract, the purchaser paying the expenses of gathering; this is supposed by some to be the most profitable way of disposing of them. The buyer erects a wooden shed, in which the daily gatherings are put, and when all are gathered they are sent to market as soon as possible. An acre of good Cherry trees sometimes yields from £30 to £40, which, considering that there is no expense attached to their culture, and that the Grass underneath can be eaten off by cattle, is by no means unprofitable. Some of the more intelligent fruit growers think that it pays better to gather and market their fruit themselves, their trees in this way being less injured and a better price being obtained for the produce. The cost of picking and marketing Cherries is about 3s. per sieve, and of this sum about 1s. 3d. goes for picking and 1s. 2d. for carriage and marketing expenses. The additional 7d. is expended in sieves, ladders, and other necessary appliances.

NUTS.—A few cultivators near London grow Nut trees, but the chief supply is from Kent. There the plants are trained up with a single stem less than 1 ft. in height, after which the branches are tied outwards to a wire or wooden hoop, so as to give them a cup-like form. All shoots rising from the centre are removed during summer. The advantage of the plants being trained in the shape just alluded to is that it admits sunlight into the centre of the plants as well as elsewhere. Sometimes a plantation of Nut trees occupies several acres in extent, the trees being fully 14 ft. in diameter, and not more than 5 ft. high at the outside. Severe pruning is adopted to keep them within bounds, and all suckers are carefully removed every year. The small wood of the previous year's growth produces the fruit, and short spurs of this are only left in winter, all gross and fruitless shoots being entirely cut away. The trees are, as a rule, to be found alternately planted with standard Apple or Pear trees, and when Apples and Pears are scarce a fair crop both of Cobnuts and Filberts is often secured. On the Kentish ragstone Filberts and Cobnuts are more grown than bush fruits. The soil just suits them and they bear abundantly. The Cobnut is more productive and profitable than the Filbert; the Nut is larger, but not so well flavoured as the Filbert, but the tree gets quicker into bearing. Sometimes a single tree, well established, has been known to bear 40 lb. of Nuts, and over £100 per acre has been made. The trees are generally planted about 16 ft. apart each way, and the pruning of them requires considerable skill and care; this is performed by men used to the work, the usual prices ranging from 2d. to 3d. per tree.

C. W. S.

THE INDOOR GARDEN.

THE PAPAW TREE.

(CARICA PAPAYA.)

THIS, with the exception of the Guava, has perhaps a wider distribution than most exotic fruit trees, being found wild nearly everywhere in tropical and sub-tropical countries, although it is now generally believed to be of South American origin. It forms a very ornamental tree in tropical gardens, and its fruits are occasionally eaten, but they are not much esteemed, not even by the natives, and still less by the majority of Europeans. It forms a small single stemmed tree, of a succulent character, 8 ft. or 10 ft. in height as a rule, although sometimes in old examples the stem is as thick as a man's body, and branched towards the top, where each stem or branch bears a crown of long-stalked, seven-lobed leaves. The individual leaves often measure 2 ft. across, and, in addition to their beauty, form a by-no-means-to-be-despised substitute for soap. The fruits, which are 3 in. or 10 in. long, by 4 in. or 5 in. broad, resemble a small Melon in size and shape. Even when cut open the likeness to a scarlet-fleshed Melon is a very close one, but the seeds are round, black, and wrinkled, resembling at first sight the pitted seeds of some of the Granadillas or large-fruited Passion Flowers. The pulp is soft and cooling, and when perfectly ripe, not unlike that of an Apricot in flavour. When plucked green, the full-grown fruit forms a substitute for Turnips, or it can be made into an agreeable sauce or preserved with sugar.

Like the Orange, Banana, Cocoa-nut, and other tropical fruits, this tree bears flowers and fruits in all stages of growth during the whole year. It is dioecious, that is to say, the male and female flowers are borne on separate plants. The male flowers are produced on long branched spikes or racemes, which grow from the axils of the leaf stalks, and are gamopetalous and tubular, being much smaller than the female flowers, which are generally solitary and large. They have a corolla, consisting of five distinct petals, and they are borne on stalks only an inch or so in length. In some cases, small abortive fruits, the size of hens' eggs, may be seen hanging from the male trees as though rudimentary ovaries had been formed in some of the male blossoms. Male flowers have not to my knowledge been noticed on the female or fruiting trees, which is the kind here represented. Throughout the West Indian Islands, where this plant is common, an infusion of the fruits or leaves, or a mixture made from the juice of the plant, is said to possess the virtue of rendering the toughest meat or poultry perfectly tender if they be immersed in the fluid, or even if

merely suspended in the tree itself for an hour or two. Recently, too, I read in a contemporary that chisels and other edged tools if too brittle might be softened by being driven into the soft stems or branches of this tree, and that this was practised by some of the natives of South America with the desired result. Other still more wonderful effects were said to belong to it.

Our illustration represents the general habit of a young fruiting specimen in company with another universal tropical product, the Sugar Cane. This, although not a fruit, and its fleshy stems being simply natural sugar sticks, is far more popular for eating or chewing wherever it is grown than most fruits. Although a native of the East Indies, it is like many other cultivated plants now naturalised in most tropical and every inter-tropical country. There are many varieties, but most of them produce jointed canes of bright golden colour, varying in height, thickness, length of the internodes, and quantity of saccharine matter produced. There are also several red, black, and purple-stemmed sorts, and one variety grown in Spain is called the "Elephant Cane," in allusion to its gigantic dimensions. Both the Papaw and Sugar Cane may be seen in cultivation at Kew.

F. W. B.

BEGONIA INGRAMI.

SOME years ago I grew this Begonia, but not finding it at all equal to be *B. semperflorens* Saundersi for winter-flowering I discarded it in favour of the latter, which is altogether less stiff and more graceful in habit. So free blooming is it that plants in 3-in. pots may often be seen laden with flowers, which appear at almost every joint, and, the colour being bright red, they have a particularly cheerful appearance. This fine variety was sent out by Messrs. Garraway, Durdham Down, near Bristol, and was much thought of in the west of England for a long time, where it was largely grown for exhibition purposes. Some time since I used to depend much on it for decorative purposes during the summer, and employed it for filling a pair of large elevated vases in a conservatory, where, from its position, it always produced a most striking effect. The new tuberous kinds are now so showy that *B. semperflorens*, good as it is, cannot be compared with them; but as these cannot be had during winter, I am always glad to fall back on *B. semperflorens*, which never fails me at that season. A good companion to it is *B. nitida*, a free flowering kind not nearly so much grown as it should be; and the same may be said of *B. insignis*, another capital plant, requiring but little heat to keep it in health. To succeed these, and come in later in the spring, *B. manicata* has no equal, its five pale pink panicles of bloom being such as to command admiration. Cut and placed in vases among flowers, nothing imparts a better finish; but to have it in a condition to last, it is necessary that plants of it be kept in a cool light stove, with their heads well up to the glass. This stiffens the stems, and imparts to the plants a more enduring character, as well as improves the colour, making it several shades darker. I should think by crossing some of the tuberous-rooted kinds with the varieties just enumerated, we should soon get kinds that would bloom naturally in an intermediate temperature during winter; at any rate, the experiment is worth trying, and, if successful, the strain would be of great use in rendering our houses and windows gay at that dull season when there is little in the floral way to cheer.

S. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Lonicera Standishi.—What your correspondent states (p. 324) in favour of this shrub is perfectly true, but, good as it is, *L. fragrantissima* is far better, its habit being more floriferous, and the perfume, as its specific name implies, of the sweetest description. One or two plants of it on a stage will scent a whole house; therefore, it is a most desirable plant to have under glass, for, except in mild winters, and when grown against a south wall, or in some similarly sheltered situation, it is very rare that it is seen in perfection. This season it has a very weather-beaten look, and its blossoms have been kept back to an unusually late period; in ordinary winters they are fully expanded by Christmas, whereas this year we had but very few till quite the end of March, and then they appeared to all rush open at once. I find that there is a great difference in the habit and general appearance of plants grown against the front of a building from others in shrubby borders, as in the former they make short, sturdy shoots from spurs which are so short-jointed as to be completely studded with flowers, while those in the latter situation make more wood and do not bloom with anything like the same freedom. In pots they do best, with the young growths kept nipped in as they are formed, a mode of treatment that increases the number of small twiggy branches to a great extent, and if these be well ripened by full exposure, each of them will bear a very large

quantity of flowers. To those engaged in bouquet making these are of much value for mounting, for, although small, they impart a refreshing perfume.—S. D.

Stokesia cyanea.—The cultural directions given for this plant (p. 345) are, according to my experience, quite correct, but simply protecting the plant when in flower in the open ground does not enable the grower to fully realise its decorative value. I would recommend Mr. Burney to take the plants up when the buds are matured and place them in the greenhouse, where they may be enjoyed in all weathers. The *Stokesia* succeeds well when thus treated, and although it has a somewhat faulty habit, the individual blooms are pleasing, and the colour is just what is wanted in the early winter months. If a quick, free, early growth be encouraged the flower-heads will mature early, and the buds will expand perfectly well when placed in a glass structure and treated in the same manner as *Chrysanthemums*. The value of the plant is imperfectly known in private gardens, where it should be grown by those who require much bloom for cutting during the late autumn and early winter months, as it may, by treating it as above described, be had in flower until late in December.—J. CORNHILL, *Buffed*.

Pimelea decussata.—Many of the *Pimeleas* are not suitable for small growers, as they require considerable skill to be expended upon their culture to bring them to perfection. The present species may, however, be grown by any one who has a glass house, and its habit being neat and compact, and the flowers bright and produced in great profusion, it can scarcely fail to give satisfaction. It should, after flowering, be potted in sandy, fibrous peat, and be placed in a cold frame. It should be syringed and kept rather close until growth commences, when more air may be given. Full exposure in the summer and autumn is necessary, in order to solidify and mature the wood. Cuttings made of the half-ripened wood will strike easily under a bell-glass in silver sand.—J. C., *Buffed*.

Cutting Asparagus.—As Asparagus is now ready for cutting, let me ask your readers to allow the earliest of the stems to grow up from the first, and to only cut those which push through the ground afterwards. The plan so often recommended of not allowing any of the stems to grow up until cutting has ceased, at the end of the season, is, in my opinion, the worst that anyone could possibly put into practice. Early growth and a long season induce perfect development, and to this rule Asparagus is no exception. The earlier the stems which have to stand during the summer are up the more thoroughly do the crowns get ripened in autumn; and this is no small advantage, especially when the roots are intended for early forcing. Not allowing the shoots to grow up until the middle of June must certainly be anything but beneficial to the plants. Moreover, the first stems are generally the strongest, and the last the weakest; therefore the latter are by no means the fittest for improving the condition of the plants. I find that by allowing about four of the first and strongest of the shoots to grow up from each root the plants are improved in every respect, and doing this does not interfere in any way afterwards with the quality of the shoots which spring up for cutting.—CAMBERIAN.

Market Garden Notes.—Rarely have the outlying market gardens presented such a bare aspect as they do now. Green crops of all kinds are sparse, and what are growing look thin and lack strength. Just now Turnip-tops are the only crop available for market. Breadths of other greens have succumbed to the frost, and white Broccoli not yet ready for cutting is thin, and has been much injured. The season continues so cold and gloomy that early-sown seeds are doing badly, and those that have grown move so slowly,

that they fast fall a prey to slugs, that, in spite of a hard winter, are evidently just as numerous as ever. Of all summer crops, perhaps, amongst vegetables, the Pea crop is the most important to the grower. Early-sown breadths have in some places done so badly, that they are being ploughed up and fresh seed sown. Other sowings are very thin, and it is only the latest that present a promising appearance. Late kinds have, to some extent, the start of the early ones, and the result will be that we shall see two or three sowings all becoming fit to gather at the same time, much to the loss of the grower, who looks to the earliest pickings from white sorts to secure the best market prices. If the white varieties are found to be only even in earliness with the blue, the latter will alone sell at a profit. Next to having no crop at all, no greater misfortune can happen to the grower than the accident of a glut in the market, as expenses of seed, growth, gathering, and marketing are calculated on a fair price, and if this be not attained a serious loss is the result. Potatoes

have been largely planted, but in consequence of the coldness of the soil none of the earliest are yet above ground. It is just possible that many of the cut sets will have rotted, and that thin rows will be seen presently. With such a cold, late season as this is, the middle to the end of April is quite early enough for planting large breadths of Potatoes.—A. D.

Vegetation in Durham.—A stroll through the woods hereabouts in search of wild flowers has sadly disappointed me. I had expected to find Primroses in abundance, instead of which I found scarcely any. Vegetation is fully six weeks later than it was last year. Then Primroses, Wood Anemones, Ribes, and other flowers were plentiful in March; this year Primroses are scarce in the last week of April; there are no Wood Anemones in bloom yet, and the buds of the Ribes have not yet expanded. Even the handsome little Pilewort (*Ranunculus Ficaria*)—the favourite flower of Wordsworth—which is often seen in February, has not yet become general. The catkins on the Hazels were very pretty a few days ago, as were also the large quantities of minute female flowers. If the present dull weather does not prevent their setting, we shall in all probability have a large crop of Nuts. The Peach blossom on walls has not yet opened, while last year it was in full bloom when that memorable storm of snow and frost set in, on the 1st of April. Although we are within a day or two of the "merrie month of May," the cuckoo has not yet been heard, nor is there any well-authenticated record that the swallow has been seen. Altogether, the "proud pied April" of the poets has been little better than its predecessor—March. If the habits of birds form any guide as to the probable state of the weather, I am afraid that we are not yet quite "out of the wood," as I saw to-day a number of fieldfares, which have not yet left us, almost a sure sign that there is more bad weather in store for us.—TYNEDALE.

Effects of the Winter in Hants.—The following are the names of a few plants which have suffered severely here during the past winter, namely, *Buddleia globosa* and *B. Lindleyana*—the latter killed altogether; *Desfontainia spinosa*, and the different kinds of *Euonymus*—the latter and the Double-flowered *Furze* killed to the ground. One or two Japan Privets are also damaged; likewise *Berberis Darwini*. The Judas tree (*Cercis Siliquastrum*) seems to be killed, and the *Laurustinus* and *Arbutus* are much damaged, and some of them are killed to the ground, although many of the latter were 10 ft. in height. A strong plant of *Magnolia Lenne*, planted last autumn against a south-east wall, and protected with Spruce Fir branches, has been killed. Pentstemons are also all dead that were left out, and *Fuchsias* are all likewise killed. Some herbaceous plants, too, have suffered; all the *Antirrhinums* are killed; two

The Papaw Tree (*Carica Papaya*) in Fruit.

plants of *Primula cortusoides grandiflora*, left out to test their hardiness, are almost dead; and *Francoa ramosa*, in a cold pit, is much injured. The blossoms of Pears on south walls are just expanding; also those of Plums on west walls. There is a good show of bloom on all kinds of fruit trees. The nightingale was heard on the 21st, and the cuckoo on the 17th.—J. C., *Furnborough*.

NOTES FROM KEW.

Hardy Plants.—Amongst the numerous varieties of Daffodils now in flower, the little kind known as Graells' Daffodil (*Narcissus Bulbocodium* var. Graellsi) is particularly noteworthy, as it is, with the exception of the beautiful single-leaved kind (*N. monophyllus*), the most distinct of all the Hoop-petticoat group. It grows about 4 in. high, with a spreading crown of blossom about 1 in. long, and of a pale yellow tint. It inhabits various parts of Spain, whence it was introduced to us a few years since; but, as yet, it is amongst the rarest of cultivated kinds. The Mountain Daffodil (*N. montanus* or *pouciflorus*) is a desirable sweet-scented kind; its large and almost white blossoms, which droop in a singular manner, distinguish it from its neighbours. The Large-flowered Erythronium (*E. grandiflorum*) flowers just in time to succeed its better known congener (*E. Dens-canis*). It grows from 6 in. to 12 in. high, and has narrower and not so prettily marked leaves as those of the last-named kind. Its blossoms are 1½ in. across, and have narrow, reflexed petals, pale yellow, with a ring of reddish brown at the inner base. It is a native of California, and is perfectly hardy. The round-leaved Thlaspi (*T. rotundifolium*) is one of the most pleasing Alpines at present in flower. It at once reminds one of *Iberis* gibraltarica in miniature, bearing, as it does, numerous heads of small blossoms of the same delicate mauve tint. It is procumbent in habit, and has small roundish leaves of a fleshy texture. It is an old introduction from the European Alps, though now of rare occurrence in collections. The Alpine variety of the common *Gentiana acaulis* is a charming plant. In the Kew specimen it may be at once distinguished from the type by the conspicuous pure white tips of the angles of the corolla, a character which tends to intensify the rich deep blue of the rest of the blossom. Very few of the *Fritillarias* produce showy flowers, though the strikingly curious markings to be found in the flowers render them suitable plants for the flower border. The best of those in flower are *F. tenella* (syn. *montana*), a species with narrow, glaucous leaves and nodding flowers, globular in form, with peculiar checkered markings of green and red chocolate colour. *F. glaucescens* so nearly resembles the last, that the distinguishing points are scarcely definable. *L. lilacea* is very distinct; it has broad foliage and large, reddish-brown, drooping flowers. *F. latifolia*, another broad-leaved kind, is similar to *F. Meleagris*, but inferior to that kind in point of beauty. The purple-flowered form of *Primula ciliata* is by far the most attractive of the *Primroses* now in blossom; the deep, rich purple of the flowers relieved by the bright golden eye at once elicits admiration. It is very similar to the kind known as *P. intermedia*, of which we gave a coloured illustration in THE GARDEN (Plate XXVIII).

Greenhouse Plants.—The New Zealand *Veronica Hulkei* is, without doubt, the finest of all the *Speedwells* for greenhouse decoration, though it is not nearly so well known as it deserves to be; indeed, the delicate lavender colour of its blossoms is so unusual that it would be difficult to name another plant of so pleasing an aspect. It is rather loose in habit, growing from 1 ft. to 3 ft. high, and it has scattered, small leaves. The flowers are borne on terminal, branching panicles in great profusion, and continue for some weeks in beauty. The dark-leaved form of *Scilla natalensis* named *sordida*—noticed last week—is no less beautiful than the original, though the pretty star-like flowers are not produced so thickly. The Fragrant *Rhododendron* (*R. fragrantissima*) is one of the most beautiful which we have seen at Kew this season. It is similar to the lovely *R. Veitchi*; its flowers are nearly as large, and they are of the same pure white as in that kind, and sweet scented. This is a variety that should be sought after for conservatory decoration, as it flowers well in a small state and is easily managed. The *Conservatory* No. 4 is now gay with Australian plants, amongst which the *Pea* family is of course predominant. Amongst these *Pultenea rosea*, with pretty rose-coloured clusters of flowers, is very desirable, as it lasts such a long time in perfection; *P. stricta* and *Eutaxia myrtifolia* are other fine kinds, which bear abundance of showy yellow and dark red flowers. The various kinds of *Adenandra* are also very attractive plants; *A. umbellata*, with deep pink blossoms, 1 in. across, and *A. fragrans*, with blossoms of about the same size, but white and fragrant, are the best. Amongst plants in flower in the Temperate House the most conspicuous is *Rhododendron Aucklandi*, from the Sikim Himalayas, certainly one of the most beautiful from that region. Its blossoms, which are very large and funnel-

shaped, are pure white, and, being subtended by numerous membranous, magenta-tinted bracts, they are very effective.

Stove Plants.—The large-leaved *Rudgea* (*R. macrophylla*) is a magnificent stove shrub introduced about a dozen years ago from the vicinity of Rio de Janeiro. Its handsome leaves measure over 1 ft. long, and they are proportionately wide. In colour they are a very deep green, which contrasts finely with the snow-white heads, from 4 in. to 6 in. across, of blossoms, which terminate each stem. The individual blooms are 1 in. long, tubular, four-cleft, and of fleshy texture, which enables them to continue for some time in perfection. Its style of growth is not elegant, as it is inclined to be leggy, but as it flowers very freely in a small state, this fault can at once be remedied. In the same house a very beautiful member of the Spiderwort family is in flower, viz., *Tradescantia fuscata*, a plant of dwarf habit with oval leaves covered with brown silky hairs. Its flowers, which are borne on very short stalks, are as large as a florin, and of a rich purple hue. For ornamenting the roof of a stove few climbers are more valuable than the old *Jasminum Sambac*, on account of its free-flowering property, and the delicious perfume of its double, bluish-tinted blossoms, which are very useful for cutting purposes. *Aschynanthus pulcher* makes a pretty basket plant; its elegant scarlet blossoms, which are produced plentifully and continuously, are highly attractive, and they hang in graceful profusion. The flowers of the Imperial *Napoleona* (*N. imperialis*) ranks, perhaps, amongst the most strikingly curious of cultivated tropical shrubs. In form they much resemble the singular zoophytes known as *Sea Anemones*. They are circular in outline, 2½ in. across, with the outer brownish-red portion membranous and spreading, and the inner part fringed and incurved and almost enclosing the bright orange centre. They are produced plentifully on the tall-growing shrubs, the deep green foliage of which forms a striking contrast to the quaint-looking blossoms. It is a native of the African jungles, and in cultivation needs an extremely moist heat to bring it to a flowering condition. W.

THE LIBRARY.

THE CHEMISTRY OF COMMON LIFE.*

BOTH professional and amateur horticulturists will find much to instruct and entertain them in Mr. Church's new edition of the late Professor Johnston's well-known work. The second edition, published a short time after Prof. Johnston's death under the editorship of the late Mr. G. H. Lewes, has long been out of print, and it seems strange that such a length of time should have been allowed to elapse before the publication of a fresh edition of one of the most popular of scientific books. Like Faraday, Liebig, Tyndall, Huxley, and a few others, Professor Johnston had the somewhat rare gift of conveying scientific truths to readers of the meanest capacity without in any way veiling or transforming them, and the present editor has done wisely in interfering with the original text and general arrangement of the matter as little as may be. Mr. Church has had the advantage of being able to refer to Professor Johnston's private and corrected copy of the first edition of "The Chemistry of Common Life," so that he has been able not only to incorporate in the present work some really valuable matter from the late author's own pen, but he has been able to learn the kind of additions which he contemplated, advantages which were not enjoyed by the editor of the second edition. Only such corrections and omissions have been made as the progress of science seemed to demand, and the addition of an all too short chapter on the "Colours we Admire" is one which Professor Johnston, had he lived a few years longer, must necessarily have added to the work as an appropriate pendant to the chapter on the "Odours we Enjoy." In this chapter Mr. Church tells us how the chemist can now build up in the laboratory from such an unpromising material as gas tar a colouring principle of great beauty known as alizarin, and, hitherto, only found in the root of the Madder plant (*Rubia tinctorum*). The material from which artificial alizarin may be formed being cheap, the manufactured product has displaced the preparations of Madder root to a great extent, so that the imports of that once valuable plant have greatly fallen off. Since this grand discovery of the means of imitating Nature's own handiwork, chemists can now imitate the processes going on in the Indigo plant, and indigo dye may be formed in the laboratory with as much certainty as alizarin, although the process is, as yet, too costly and elaborate to be commercially available. Every year, however, sees new discoveries in the direction of manufacturing natural bodies hitherto only found in plants, and we

* "The Chemistry of Common Life." By the late Professor JAMES F. W. JOHNSTON, F.R.S., &c. Second edition revised and brought down to the present time by ARTHUR H. CHURCH, M.A., &c. W. Blackwood & Sons, Edinburgh and London. 1879.

must not be surprised if some day we hear of a cheap method of building up ordinary sugar in the same way as we now build up alizarin and indigo. We also have an interesting account of colein, a colouring matter discovered by Mr. Church himself in the leaves of the *Coleus Verschaffeltii*, which seems to be closely akin to, if not identical with, the colouring matter of Red Cabbage, red wine, most red, blue, and purple flowers and fruits, as well as with the red pigment of the Copper Beech. Colein is a red, resinous-looking substance, which will not dissolve in ether and only slightly in water, but is very soluble in spirits of wine. With a drop of ammonia solution colein turns purple, violet, indigo, green, and yellow, while with a drop of acid it takes a scarlet hue. Can it be, one may ask, that the ever varying hues of flowers are due to the different degrees of the alkalinity or acidity of the juices contained in their petals? It is to be hoped that Mr. Church will pursue his researches in this direction. In a leaf of a *Coleus*, say *Coleus Verschaffeltii*, the colouring matter is very irregularly distributed in the cells of the epidermis, some of them containing much, some a trace, and others none at all. The hairs of the stem and leaf of this plant form most interesting microscopic objects; one hair, for instance, say of six cells, may have the end cells richly tinted, while the rest are quite colourless, or the exact reverse may be the case. The leaves of variegated plants afford a vast field of research, both to the botanist, chemist, and microscopist.

As for the ordinary leaf-green, or chlorophyll, as it is called, Mr. Church frankly allows that, although it exists in thousands of tons all around us, chemists have not yet ascertained its component elements, much less their relative proportions. They are uncertain whether it contains nitrogen or iron, or whether it consists of one or more colouring matters. In this respect chemists appear to resemble certain horticulturists, who, instead of trying to improve old and valued subjects, use all their endeavours to produce novelties, whose worth is, to say the least, problematical. The other chapters which will interest our readers are the following: "The Soil we Cultivate," which not only treats of the different kinds of soil, but of their varying constituents and their influence on the growth of different species of plants; "The Plants we Rear," the title of which sufficiently explains its contents; "The Bread we Eat," which fully describes Wheat and its substitutes, such as Rye, Oats, Indian Corn, Buckwheat, Rice, the Potato, the Plantain, the Sago Palm, &c.; and the three chapters on "The Beverages we Infuse," including not only Tea, Coffee, and Cocoa, but their thousand-and-one substitutes; "The Sweets in Extract" from the Cane, Beetroot, Date Palm, Maple, Sorghum, and other sugar-yielding plants. "The Liquors we Ferment" are so numerous, that their description occupies three whole chapters; while bread and bread-stuffs only take up a single one. It is another lamentable sign of human weakness that "The Narcotics we Indulge" take up no fewer than eight chapters, or nearly a quarter of the whole book. These are valuable from a philosophical point of view, as showing that the lowest tribes of savages are just as prone to seek for temporary comfort in the use of narcotics as the most highly-cultivated European. It would take up too much space to give even a list of the whole of the narcotics described in the present edition of Professor Johnston's work, but a few of them may be selected from localities which are sufficiently far apart to show the prevalence of this form of indulgence. India has its Opium, Hashish and Betel; Polynesia its daily Ava; Peru its Coca; the Florida Indians their emetic Holly; the Tartars of the Himalayas their Thorn Apple; the Englishman and German their Hops, and we may say all the world its Tobacco. "The Odours we Enjoy," and, as we have said before, "The Colours we Admire," may be read with profit and with pleasure by all.

A full index will help the reader to a knowledge of the special subjects of which the book treats.

CHARLES W. QUIN.

HOVEY'S FRUITS OF AMERICA.

MR. HOVEY has sent us some numbers of this really noble work, which was begun with the idea of figuring in colours all the fruits of that country, whether of native or foreign origin. The plates are well drawn and coloured and the descriptions full and accurate; in fact, we very much want in England a book on fruits equally satisfactory in respect to full and exhaustive descriptions, such as those of Mr. Hovey and M. Leroy. This book was, unfortunately, not completed, owing to the great war in America, when the price of paper suddenly increased to such a degree that the price of the paper alone amounted to more than the announced price of the book. It had, therefore, to be discontinued, but not before a good deal of useful work was done. We quote the following account of the Dix Pear:—

Few, if any, of our native Pears hold a higher rank than the Dix. The large size, beautiful appearance, and exquisite flavour of its

fruit, added to the vigour and hardness of the tree, its productiveness, constant bearing, and period of maturity, give it a combination of qualities which but few varieties possess. When originally brought into notice, in 1829, it was pronounced "one of the very best autumn Pears, which might, with the greatest safety, be introduced into our gardens;" and twenty years' experience have fully confirmed the correctness of that opinion.

The Dix originated in Boston, in the garden of Madame Dix, in compliment to whom it was named, about thirty-five years ago. The tree sprang from seed near the house, and grew so rapidly, that in 1829 it had attained the height of 23 ft., with a stem 10 in. in diameter; it still stands in the same spot, and has now become a very large tree. It first began to bear in 1823, but did not produce a full crop till 1829, since which time it has continued to bear abundant crops of fine fruit.

The Dix is very late in coming into bearing, and, on this account, cultivators have often rejected it in making a selection of fine Pears. The average period of its fruiting is eight or ten years, occasionally in four or five, but oftener twelve and upwards. It has, however, the good quality of constant bearing after it has attained a fruiting state, and the Pears ripen off as freely as the Baldwin Apple. It does not succeed upon the Quince unless double-worked.

The Dix is one of the most marked varieties in the nursery. The wood is almost as yellow, smooth, and slender as a Willow; but the tree has an erect and upright habit, and in time forms a large and fine head.

TREES.—Vigorous, upright, with rather long and slender annual shoots, occasionally thorny, horizontal at first, but erect at the ends; as the branches become older they assume a rather straggling habit.

WOOD.—Clear light yellow, smooth and glossy, with very minute dots, slender and rather long-jointed; old wood, pale olive-yellow; buds, medium size, roundish-ovate, slightly diverging, with very prominent shoulders; flower-buds, medium size.

LEAVES.—Small, ovate, light green, broadest in the middle, tapering to each end, little recurved on the midrib, slightly wavy, and somewhat reflexed at the edges, with a smooth and glossy surface, and very finely serrated; petioles long, about 2 in. in length, slender.

FLOWERS.—Medium size, petals narrow.

FRUIT.—Large, about 4 in. long and $3\frac{1}{2}$ in. in diameter; form, oblong, inclining to pyramidal, regular, largest in the middle, tapering to an obtuse point at the stem; skin, slightly rough, greenish-yellow, becoming pale yellow when mature, broadly tinged with pale red in the sun, and mottled with dots of a deeper shade, often russeted around the crown, and regularly and thickly covered with large, distinct russet specks; stem, medium length, about 1 in. long, rather stout, curved, and inserted in a shallow cavity, formed by swellings and projections of the fruit, highest on one side; eye, medium size, open, and slightly sunk in a very shallow, plaited, or furrowed basin; segments of the calyx short, stiff, projecting; flesh, yellowish-white, coarse, melting, and juicy; flavour, rich, sugary, slightly vinous, perfumed, and delicious; core, rather large; seeds, small. Ripe in November, and keeps four or five weeks.

Provincial Spring Flower Shows.—I am glad that double Primroses have found so many friends to help their cause. If only our provincial horticultural societies could be prevailed on to hold exhibitions of spring flowers (as is done in London) in April or in the early part of May, emulation would be excited among growers of hardy early blooming plants, and many a flower would thus be brought into notice which at present is born to blush unseen. A corn-hall, assembly-room, a drill-hall or disused rink, would each make a good exhibition room, and I think, in a pecuniary point of view, we would find such a flower show to answer. Out-of-door exhibitions, even in July and September, are often spoiled by bad weather; but there would be no risk of such misfortune to a show held under cover, and to which so many persons would eagerly flock, anxious to obtain a glimpse of early floral beauty. Moreover, an exhibition of hardy flowers would open a wider field for competition among a large class of cultivators, who are debarred by circumstances from contesting for prizes offered for specimen plants and stove exotics, the culture of which demand artificial heat, space, and labour. But Auriculas, Alpines, Primroses, Polyanthus, Hyacinths, Dutch Tulips, Squills, Daffodils, Cyclamens, Anemones, &c., are readily grown, while it would be easy for those who have forcing-houses to add their quota, so as to make our country spring shows a success to the promoters and a delight to the beholders. Will not more than one provincial floricultural society take this matter in hand, and announce a show of this description for May 1, 1880?—C. R.

PLATE CLXXXVIII.

HARDY ANNUAL HAIRBELLS.

(WITH A COLOURED FIGURE OF *CAMPANULA MACROSTYLA*.)

WITH but few exceptions the whole of the numerous family of Hairbells are very handsome, and those of annual duration comprise some of the most showy. To this group belongs the subject of the accompanying illustration, the recent introduction of which to our list of beautiful hardy annuals must be regarded as a decided acquisition. It is rather dwarf in growth, seldom exceeding 1 ft. high, and a good idea of its singular habit may be gleaned from the subjoined woodcut, from which it will be seen that the numerous branches which are but sparsely clothed with foliage, are arranged in a candelabra-like manner, and which in addition to the large size and pleasing colour of the blossoms, with the beautiful net-like veins of a deeper shade, render it highly attractive. Its specific name *macrostyla*, or large style, is given on account of an unusually excessive development of that organ, which is club-shaped, and rises erect from the centre of the blossom. It is found growing in sandy soil in the vicinity of Lake Isauria, near Mount Taurus, in Asia Minor, whence it was first introduced a year or two ago.

A rich light soil in an exposed and sunny position seems to meet its requirements. It may be sown in the open border, either during the spring months or in September, to stand the winter so as to obtain flowers early in the season.

Campanula macrostyla.

Besides this handsome novelty there are several other species of the annual class that are very desirable, and which have long been esteemed as good old-fashioned border flowers. The best of these are—

Lorey's Hairbell (*Campanula Loreyi*).—An old introduction from Mount Baldi, in North Italy. It grows 9 in. to 1 ft. high, has numerous branches and small, stalkless, shining leaves. Its blossoms are of a blue-violet colour, and are produced in sufficient quantity to render it a pretty border annual; it is seen to the best advantage when planted in masses. Its variety called *alba*, with blossoms of silvery-grey, is also very attractive.

Löffling's Hairbell (*C. Löfflingi*).—This is a showy species, dwarf in habit, rarely exceeding 4 in. high, and it produces a profusion of violet-blue blossoms 3 in. across. It is a capital plant for the summer decoration of rockwork, or for front spaces in ordinary borders. It is found growing naturally in the cornfields throughout Portugal and Spain.

C. atica.—This is another miniature species, about 3 in. high, with reddish-purple flowers, which are produced abundantly throughout the summer. Its white variety is very pretty, and when intermixed with the original kind is strikingly effective.

The Strigose Hairbell (*C. strigosa*) is a native of Aleppo and other parts of Syria, whence it was introduced a few years since. It grows about 4 in. high, is a profuse flowerer, and lasts long without any abatement in beauty. Its blossoms are 1 in. across, of a dark blue colour, the rather long tube being of a pale yellow shade.

Venus' Looking-glass (*Specularia Perfoliata*).—Though this fine old annual cannot be strictly classed with the Campanulas, it is so often ranked with them that an allusion to it under this head is, on this account, admissible. It is, without doubt, one of our showiest annuals, and besides the large-flowered form called *grandiflora*, both in purple and white, we have the double-flowered kind, which is said to come true from seed, and a procumbent variety dwarf and compact in habit, and bearing violet-blue flowers.

S. pentagonia.—This is another well-known favourite with larger flowers than the last, but less profusely produced. Its colour is purple, with the centre of a deep blue shade. This and the foregoing are particularly desirable, for, in addition to their showiness, they invariably scatter their own seeds, which come up after year and give no further trouble; therefore they are as useful as the perennial kinds. W. G.

EFFECT OF LOCAL INFLUENCES ON GARDEN CULTURE.

I HAVE a large garden, ten miles distant from any town, furnished with the usual appliances for the cultivation of both hardy and tender plants; I have an extensive knowledge, both practical and theoretical, of their culture—in fact, with my horticultural friends, I am accepted as the local authority on the subject; yet here, even with extra care, the commonest plants, such as *Fuchsias*, *Pelargoniums*, *Chrysanthemums*, &c., cannot be induced to make a moderately healthy growth. These easily grown plants better illustrate the difficulty to which I wish to direct attention; but my remarks apply equally to stove plants, Orchids, and others requiring more special treatment. The cause of the mischief affects almost all classes of plants which I attempt to grow. My garden is unfavourably situated on a clay subsoil, but this can scarcely influence to an extent so injurious plants grown under glass in soil suitable to them, more especially as the evil of which I complain is increasing. I could, a few years ago, obtain fair results from the cultivation of many plants which now refuse to grow. I have changed my head gardener five times in seven years, hoping to find one who could master the difficulty; I have been men of experience, who had been successful growers, and who would probably again succeed elsewhere. Here all failed alike, and admitted their failure. My present gardener, formerly plant grower for three years in a large provincial nursery, admits the facts as I state them, but is utterly at a loss for an explanation. As may be expected with unhealthy plants, insects thrive—the mealy bug especially delights in the place. It does not confine itself to the stoves, but revels equally in the cooler houses, and even on plants in the open ground. But insects are not the cause of the mischief, or at any rate any insect known to me and visible, for ordinary measures are taken for their repression, and I can measure the damage done by them. I have suspected the water, but the plants seem to behave the same, whether watered from the covered tanks in which the rain is collected or from a well. I have often heard of isolated cases of failure, such as a good gardener at a former place, celebrated for exceptionally fine specimens of *Adiantum Farleyense*, being unable at his next place, although circumstances and appliances were apparently equally favourable, to induce it to grow; but I have heard of no case similar to my own, where the difficulty affects many plants of the easiest cultivation.

The question which I wish to submit for solution is: Has anyone noticed a local condition, irrespective of the ordinary influences affecting the health of plants, which prevents the development of growth usually following on proper cultivation? Strange and exceptional as is my failure, it cannot be unique. The same causes, whatever they may be, must have produced similar effects elsewhere; I therefore write in the hope that some one of your readers, recognising a former difficulty of his own, and more fortunate than I in discovering the cause and remedy, may, in kindly sympathy with a fellow-horticulturist, publish his experience for the public benefit.

Warwickshire.

E. T.

Hardy Border Plants.—It may be well to remind all who love to see their garden borders gay with flowers that just now is a good and proper time to sow in the open ground seeds of Wallflowers, Stocks, Canterbury Bells, *Pentstemons*, *Antirrhinums*, *Pansies*, *Polyanthuses*, and many other favourite hardy flowers. The place selected for sowing should be a warm one, exposed to the full light of the sun, as it is desirable that both seed and soil should have all the benefit of solar heat should the weather prove dull and cold, as it does sometimes in May. During hot bright days it is easy to give a little shading whilst the sun is high, but warmth is entirely essential to the free germination of the seed. *Pentstemons* and *Canterbury Bells* would germinate quickest under glass.—A. D.

GARDENING FOR THE WEEK.

Flower Garden.

Auriculas.—A midland county Auricula grower writes for information respecting the construction of garden frames for these flowers, and his letter would lead one to infer that there is an impression abroad that frames and houses of a peculiar construction are necessary for Auriculas. If that be so, the impression is an erroneous one. Our frames at Loxford are simply ordinary Cucumber frames, and no system of side ventilation is provided. In summer the frames are elevated on bricks placed at each corner. Whenever the weather is fine, we pull the lights quite off, and do not trouble about the cold; Auriculas may suffer from heat in summer, but never from cold. Another correspondent lost his collection last winter from frost, so he says; but that cannot be the case, as extraordinary circumstances no Auricula suffers from frost even during the severest winter. They may be killed by kindness, or they may be starved by neglect, but the weather must not be blamed. Whenever an unsuccessful grower is met, there is the usual remark about the "horrible weather," which never suits such people. It will be time next week to begin potting. If the soil be not prepared, see to that matter at once, and get the pots in readiness.

Carnations and Picotees.—At this date last year we had begun to place sticks to the flower-stems, and a few of the earliest had been disbudded; but, unless there is a considerable change in the weather, they will not be so far advanced for at least a fortnight yet. Those who can keep their plants in cold frames will certainly have a considerable advantage this season over those who have no such means of protection. With the most careful searching of the soil, it is not possible to remove all the wireworms, and we have lost a considerable number of our best plants through that pest, and we must expect to lose a few yet. Whenever a plant shows signs of flagging, examine the underground round the stem, when the wireworm will be found; but probably by that time the mischief will be done.

Dahlias.—There is little to add to what has been already stated in previous numbers respecting these plants. See that they are secure from frost, that they are not overcrowded in the frames or pits, and be sure they have abundance of ventilation, removing the lights entirely whenever the weather permits. The foundation of future success lies in a stocky, firm growth and rigid, deep green leaves at the present time. When plants are received from the nursery in 2½-in. pots shift them at once into 3-in. pots into good rich mould and place them in a warm house near the glass for a few days in order to encourage root action.

Phloxes, Pyrethrums, Pentstemons, &c., in Pots.—These hardy border plants may be classed together for convenience sake. Their culture is much the same; they require good rich loam and 8-in. or 9-in. pots, well drained, for plants with four or five stems. The flowering-stems are now well advanced and the pots are filled with roots; if there is any lack of vigour give manure water weak at every alternate watering. Support the stems with suitable sticks. This class of plants require a considerable supply of water at the roots, and they suffer if that be neglected even for a day; they show signs of distress by the oldest leaves becoming yellow and the stems hard and wiry. They should all be out-of-doors now, sheltered if possible from the north-west winds.

Polyanthuses.—These are much more lasting than Auriculas; the centre truss comes up first, and small trusses are produced for a few weeks afterwards, therefore the same plant will remain in flower, if kept in a cool place and shaded from the sun, for at least six weeks. The leaves under glass have a tendency to become drawn; it is therefore better to remove the lights altogether in fine weather and admit air at night. Water freely and remove all decaying blooms; as they go out of flower place the plants on a cool bottom out-of-doors for a time.—J. DOUGLAS.

Orchids.

Beetles and Ants.—Most Orchids requiring a high temperature will now be in an active state; the greater portion, such as the majority of Vandas, Aerides, and Saccolabiums, that flower in spring and early summer, will be fast pushing up their bloom spikes, and those who have to contend with the destructive beetles will need to be continually on the look-out to protect the advancing flowers from their depredations. The usual plan is to put a piece of cotton-wool round the flower-stem, but I have found ordinary wool for this purpose better, inasmuch as when it gets wet through syringing, the moisture makes little difference to it; not so with cotton, which, when much saturated with water, gets into a close compact mass, and does not offer such an effectual barrier to the approach of the beetles. Where these are present, as they almost invariably are

where any considerable number of plants are grown, it is much better to keep on continuously trapping them than to allow them to rest for awhile until they have become numerous, and then to be under the necessity of making extra efforts to reduce them. Independent of the annoyance resulting from the loss of flowers which they destroy, when allowed to get numerous they do immense injury to the plants, especially the thick-rooted species, by eating the tender points of the roots. I have seen collections so seriously attacked in this way, that were it not for the recuperative powers which these plants possess they would have been destroyed outright, and as it was, both their growing and flowering capabilities were very much reduced. I have tried all or almost all the different poison preparations made for their destruction, all of which kill more or less of them, but amongst those whose destructive power is derived from phosphorus, I have found none equal to Roth and Ringeson's beetle poison; like others, however, it very soon dries up, in which condition it is useless. With the help of this laid down for a couple of nights at a time, at intervals of a month, and small marmalade pots half filled with olive oil or treacle, and placed so as to touch the pots of the plants in which the insects lodge, or anywhere near where they hide, they may always be kept so few in number as to do little harm. Where ants exist to an extent to be troublesome, the oil or treacle will be sufficient to keep them down. In their case it is better to use both alternately, as, from their keen instinct, if the oil be always present they soon learn to avoid it.

Shading.—So far, I scarcely remember a season when we have had so little sunshine; the effect of this will be that when it comes continuous and powerful, the plants will be less able to bear it, and, where fixed shadings were put on as early as it became necessary to use any at all, the weakening influence in the case of such a spring as this will be much worse than usual. One of the most successful growers of Orchids, especially of East Indian ones, with whom I recently conversed, informed me that he had become so convinced of the evils attending too heavy shading, even when moveable, that for the last two seasons he had used it very much thinner than for thirty years he had ever previously done, with the obvious result of shorter, stouter foliage, particularly in the case of such plants as Vandas, Aerides, and Saccolabiums, and with a proportionate increase not only in the number of spikes produced by each growth, but also in the quantity of flowers which they bore. The plants furnished good evidence that rude health and a disposition to flower are both the result of an increased amount of light, which ripens and solidifies the growth during the process of formation.

Ventilation, &c.—The cold, cutting east winds that have continued so long have made the admission of air a difficult matter, yet every day, if even for a few hours, enough should be given to dry up the atmosphere of the house, by which means more moisture may with safety be indulged in for some hours after closing. Avoid high night temperatures, as they are most baneful in their effects. It seems singular, but I have long noticed that Orchids which inhabit even the hottest countries will not long keep in good health if submitted to so high a night temperature as that in which hard-wooded species of plants that come from the same countries will thrive. Difference of opinion exists amongst Orchid growers as to syringing overhead during the growing season, some practising it regularly and others little or not at all. Its effects a good deal depend upon the light or dark character of the house in which the plants are grown, their proximity to the glass, the volume of light during the time the sun is on the glass that is allowed to reach them, and also the more or less air and atmospheric moisture that is applied. My own impression is that, with the exception of a very few species, if the plants have not stamina enough in them to bear syringing overhead without injury, the general conditions of cultivation under which they are grown are such as not to be compatible with a healthy existence for any considerable length of time.

Vanda teres.—This most distinct and beautiful species, the individual flowers of which are equalled by very few, requires special treatment in order to bloom it regularly every year. It is indigenous to different parts of the East, and, to some extent, no doubt this will have an influence upon its disposition to produce flowers in the case of individual plants; but, by growing it in the lightest position in the house, with the top not more than 6 in. or 1 ft. away from the roof glass, and by withholding water altogether from the middle or end of November through the winter, during which time a temperature of 55° will be enough, it may be induced to flower; with more than this temperature, unless there is very little atmospheric moisture, it never gets quite at rest, a condition indispensable to its blooming. If, about the middle of March, the plants be put amongst the warmest section, but no water applied until the flower-buds have broken from the stem, I have found it to bloom as freely as any other species; after this water may be given, but, if applied earlier, with me, at least, the plants always went off into growth.—T. BAINES.

Ferns.

In planting a house with Ferns, care is required to arrange them in such a way that the stronger growers will not encroach upon and destroy the weaker ones, and attention in after years will also be necessary to keep the large ones within bounds. This will be easily effected by cutting away the oldest fronds to a greater or less extent, an operation which has the direct effect of reducing the strength and size of those produced immediately afterwards. This not only applies to the lower-growing kinds with creeping rhizomes, but also to the tree species; consequently, by a judicious removal of a sufficient number of the old fronds whilst there is yet vitality in them, the extension of those forthcoming can be regulated to a nicety; but it may be necessary to inform the inexperienced that this frond-cutting must not be carried too far, or much injury will be the result, as, if many of the evergreen species with a creeping habit of growth have the whole or the greater portions of their fronds removed at once, many of the rhizomes will die; as a rule, the stronger habited the plant the more cutting it will bear. Complete removal of the old fronds, if they happen to get into bad condition through being infested with scale, such as is sometimes practised on the hardier kinds of *Adiantum*, should never occur in the case of any less able to withstand mutilation. I have frequently seen plants more or less strong of *Gleichenia*, summarily treated in this way, either wholly or partly die. A very much better plan with any, but especially with valuable plants of this description, is to kill the scale by thoroughly syringing the whole head right down to the surface of the soil with a strong solution of insecticide; even if to effect the certain destruction of the insects the application be given so strong as to more or less disfigure the foliage, it will be very much less injurious to the plant ultimately than removing all the fronds at once.

Propagation of *Gleichenias*.—These are not nearly so plentiful as they deserve to be, taking into consideration their beauty and usefulness. They need comparatively very little artificial warmth to grow them well, and they do immeasurably better in a dry position, such as that immediately over exposed hot-water pipes, or a flue, than elsewhere, conditions that would at once stop the healthy development of most Ferns. One reason why *Gleichenias* remain scarce is, that they cannot be propagated by division nearly so readily as most other Ferns, for their rhizomes will not bear dividing into small pieces like the generality of Ferns; but where healthy, vigorous specimens exist, they push their creeping roots rapidly at this time of the year over the sides of the pots or tubs which they occupy, and, if as they extend they are layered into small pots, drained and filled with peaty soil, and fixed in a continuous row round the large pots in which the plants are growing, and secured, as they easily can be, by a few strands of wire, a large quantity of young plants can be thus obtained, but the operation requires care in carrying out, as these young extending rhizomes are so soft, delicate, and susceptible of injury as the growing extremities of an Orchid root; and if, on the other hand, the layering be not effected until the rhizomes have extended a considerable way over the sides of the pots, and have got into a hard, stunted condition, they are little disposed to grow freely after they are layered; consequently it is best to prepare a sufficient number of little pots for layering, and fix them in position just as the creeping roots are about to extend beyond the rim of the pot in which the plant being propagated from is growing. With a good vigorous specimen, these push so fast at this season that in a few weeks they get sufficiently advanced to layer, and also form roots in proportionately little time, but in directing and securing these young root-growths to the small pots in which they are to be layered, very great care must be taken not to injure them. I have found bits of lead sufficiently heavy to hold them in contact with the soil less injurious than the hooked sticks or similar appliances generally employed for that purpose.—T. BAINES.

Indoor Fruit Department.

Vines.—Too much stress cannot be laid on the importance of starting late Vines sufficiently early for the crops to be perfectly ripe before the end of September, when they may be kept sound with little or no trouble. Ours were thoroughly matured by the beginning of September, and we have yet a goodly number of bunches as plump and fresh as when they were cut at Christmas time, and not a bad berry has had to be cut out of them, a circumstance wholly attributable to early maturity. All late Vines should therefore now be ready to disbud, and be grown on freely by taking advantage of sunny days, to close up early, running up the temperature to 90°, or even more, along with abundance of air-moisture. Inside borders are preferable for late as well as for early Grapes, and though they cause additional labour as regards watering, the advantages gained by the power to feed at will, and by being independent of the weather, more than balance accounts for extra labour. See that all inside borders are well moistened through

before the Vines flower; outside borders will, of the two, rather require to be protected from water than be given any. Of sunshine we have still but little; early Grapes, therefore, make but slow progress, and, unfortunately, many are expected to have them ripe by a certain day. Where such is the case they must continue to force at all cost, but the warning must be given that the strain will probably be too much for the Vines, and though they may finish up fairly well this season, next year the injury will become apparent. It is always better to wait an extra week or two for ripe fruit than to permanently injure the Vines by excessive forcing. Where Grapes are colouring, ventilate freely night and day. There should now at all times be a slight current of rarified air in the house, and the temperature should be maintained at a minimum of 60° degrees on the coldest nights. Atmospheric moisture must still be maintained, but only in moderation, and on warm days give air rather freely, in order to allow the stagnant moisture to pass off, otherwise mildew might be engendered. Tie down and stop the shoots in successional houses, and do not be afraid of leaving too many growths or too long shoots, provided there is space for full development without overcrowding. In thinning out the berries, keep in mind the variety being operated on, and thin little or much accordingly, erring rather than otherwise on the side of overthinning, when the Grapes are intended for long keeping. Pot Vines that are intended for fruiting next season should be potted on as soon as the roots have reached the sides of the pots, for if once they get entangled together before a shift is given, they sustain a severe check by the operation; grow them on without bottom heat as near the glass as possible, and with abundance of atmospheric moisture. Stop the main shoots as soon as they have become 6 ft. in length, and the lateral shoots at the second leaf.

Peaches and Nectarines.—Routine work amongst these will now consist in keeping the strong growths pinched and the whole neatly tied in, avoiding overcrowding. Expose as much as possible the whole of the fruit to full daylight; this is necessary, both as regards free swelling and high colour. Give abundance of tepid liquid manure as soon as the second swelling of the fruit is perceptible; in well-drained borders it is hardly possible to give too much. Well syringe the trees night and morning, and maintain a moist, ammonia-charged atmosphere by sprinkling manure water on the floors and walls till the fruit begins to colour, when it should be discontinued. Late houses should now be finally disbudded, well syringed, and abundantly supplied with water. Give no quarter to green or black fly, but fumigate immediately any are perceived.

Strawberries.—Attention as to abundant supplies of water, ventilation, and thinning out of surplus fruit is about all these now need; taking it for granted that there are good plants upon which to operate, abundance of good fruit must be the result. The later plants are throwing up their flower-stems, and should therefore not be retarded, but be encouraged to make sturdy growth, by giving them plenty of room and turning their crowns sunwards. A cold pit on which the lights could be put at night is a suitable position till they are required for introduction to the forcing pit. Plants from which the fruit has been gathered should be gradually hardened off preparatory to forming new plantations, which can now be made at any time. Any fruit requiring to be retarded may, if removed to a cool fruit room before it is dead ripe, be kept for a week or ten days.—W. W.

Kitchen Garden.

We have now had about seven months of wintry weather, in the shape of a succession of snow, hail, and rain storms, varied occasionally by biting north and north-east winds, which we bore meekly, inasmuch as they dried the ground and allowed seed to be sown; but, judging by present appearances of many of the seedlings, even this work would have been best left alone, for to say that they look sickly is to very inaptly describe their condition; and, however mild the weather may now become, many vegetables will be very late, and will need all the cultural aid that can be given them if they are to attain anything like perfection this season. It is by paying strict attention to the smallest details that success is to be attained; therefore, beginning with the seedlings, these should always be thinned before there is the slightest danger of disturbing the roots of those that are to remain. Many crops are irretrievably injured by neglect in regard to thinning them at the proper time. Onions, Carrots, Parsnips, Turnips, and kindred subjects, should all be thinned out as soon as they are large enough to handle, and afterwards the ground between the rows should be deeply stirred. The main crops of Beetroot, Broccoli, and Kale should now be sown. Broccoli requires light, deep soil, free from rank manure, its best fertiliser being soot or a surface-dressing of guano as soon as the seed is sown. For heavy, tenacious soils, burnt earth, charcoal, and wood ashes are preferable. French and Runner Beans may now be sown in quantity. Amongst the different sorts the best for a main crop is

the Canadian Wonder; if sown thinly in rows, 30 in. apart, it will require small Birch twigs to support it, as, under good culture, it is a prodigious cropper. As a Runner Bean none equals Sutton's Giant White, a kind a long way in advance of the ordinary Scarlet Runner, as it bears to the very bottom of the haulm, and continues bearing throughout the season, if well mulched or watered in dry weather. Cauliflower plants that were wintered in handlights are growing well in spite of the weather; these require high feeding, and, should the weather turn out to be dry, a dose of liquid manure will be of the greatest assistance to them. Plant out successional batches, and also spring-sown Cabbages and Coleworts, which will come in for early autumn use. Brussels Sprouts are a most important crop, for amongst all the winter greens these have proved this winter to be about the hardest. The main crop should now be planted; 3 ft. row from row, and 2 ft. plant from plant is none too much. Thin out the seedlings of any that were sown in rows for a permanency. After several years trial we can pronounce this to be the best system of culture, its only drawback being that ground cannot at all times be spared to thus sow them. Main crop Peas must now be sown in quantity, in doing which it is well to forestall the weather, and sow them in trenches, in order that in the event of drought supervening, they can be well watered, as these, like Cauliflowers, are thirsty subjects, and resent dryness, by the production of mildew, instead of Peas. Earth up and stake advancing crops, and if an extra early dish be desired, pinch out the tops; the lateral growths will soon show blossom, but, of course, this is at the sacrifice of produce. We cut the first Asparagus from the open ground on the 26th ult., three weeks later than usual, and Asparagus is by no means looking so kindly as it usually does the first week in April. This should now be looked over every morning in order that all heads may be cut before there is the least trace of the buds at the tips of the shoots opening. Now is the time to make new plantations, before doing which beginners would do well to examine the illustrations and instructions given in p. 344 of last week's GARDEN. Plots of ground that have been occupied with winter greens will now be becoming vacant, and should be dug or trenched according to the crop intended to be sown or planted on them. If for Celery, simply clear off the stumps and dig out and manure the trenches; and if time and labour be scarce, the same mode of culture will answer for Peas, but preference should be given to entire trenching, when time and labour admit of it. Forcing properly, so called, was now to be at an end; all salads and early vegetables in frames should now have full exposure except on cold nights, and a constant succession of small salads must be kept up by frequent sowings in the open air. Tomatoes, Capsicums, Ridge Cucumbers, and Vegetable Marrows should be potted ere the roots get entangled together, and be grown on sturdily till the last week of this month, when they may be transplanted to their fruiting positions, either near south walls, on south borders, or in other sunny sheltered spots. Prick out Celery, Cauliflower, and herb seedlings, and grow them on with partial protection so long as cold winds and frosts continue.—W. W.

Parks and Open Spaces.

Freeing Roads and Walks from Weeds.—During May these will require particular attention in regard to weeding, the old method of hand-picking being yet the best. The objections to this system are the amount of time taken up in the work, the impossibility of pulling up the very small weeds which show themselves after the first shower, the loose surface left should there be many weeds, and that hand-weeding does not destroy any seeds which may exist in the gravel. Corrosive acids have been recommended for clearing weeds from walks, and also salt, but these, although effective, if used of sufficient strength and in sufficient quantity, can only be applied with great care, as any vegetation in the shape of edgings with which they may come in contact will be sure to suffer more or less. Acids are also destructive to watering-pots, clothes, &c., and they will be found expensive, whilst salt is unsightly, as, to be effective, it should lie on the surface for some time, its effect when used with water in a boiling state being less satisfactory than when used in a dry condition. It must also be remembered that whether acids or salt are used the weeds remain for some time in a withered condition on the surface. Generally when roads and walks are made with a view to utility, the work of weeding is trifling; but if broad roads and walks little used exist, they are certain to become extremely troublesome in this respect. Sulphuric acid (vitriol) is perhaps the most efficacious for the purpose of killing vegetation, and it should be diluted with 20, 30, or 40 times its volume, according to and in proportion to its concentration. Salt used in a dry state may be put on at the rate of from 2 lb. to 4 lb. per square yard with boiling water. It matters very little the quantity used, provided it be not less than that recommended in a dry state. The action of both acids and salt is not permanent, but may, if well done, last the summer and autumn. The best time for applying them is during dry weather, as weeds are

then in a state to take up the maximum of the poison applied. Hand picking should be done in moist weather, the weeds coming up better when the paths are in a soft state, and if well rolled, the effect is more easily obliterated. A combination of both methods may be tried with advantage. In dry weather roads and walks should be watered to prevent dust, especially in the vicinity of flower beds, and also in order that the stones may not become loosened in consequence of the grit, which assists in binding them together, being blown away, whilst on wet days rolling should by no means be neglected.—C. DENNIS, *Southwark Park*.

ROSES.

NEW ROSES, FRENCH AND ENGLISH.

THE article which I wrote for THE GARDEN on this subject has brought me into correspondence with one of the best known and most zealous of French horticulturists, who has taken exception to some of the views I have expressed, and has also given expression to some things with which, on my part, I cannot coincide. This, and the appearance of one or two articles in the "Journal des Roses," and the fact that two fine French Roses were admirably figured in THE GARDEN (p. 298), have induced me to follow up the subject, taking up the objections of my correspondent, and adding such facts as may be of interest on the subject, for we have abundant evidence that nothing connected with the queen of flowers is out of place or uninteresting.

I had animadverted on the very great number of worthless Roses which have been introduced annually for a number of years, puzzling our Rose growers, causing bitter disappointment, and worrying our amateurs as to whether they shall trust the glowing descriptions which our English nurserymen cannot endorse for lack of information. To this it is replied, that in the main it is true that far too many Roses are sent out, and that it would be a great deal better if they were curtailed; but it is also said that there is not the needed facility for bringing Roses under the cognizance of some competent tribunal, and that Rose growers at Lyons, or Brie-Comte-Robert, may each of them have what they believe to be good Roses, good enough to send into commerce, but that probably had they had the opportunity of seeing one another's flowers, they might have hesitated. I admit all this; I never imputed dishonesty but lack of judgment, and that blindness in the case of one's own progeny, which affects other things besides Roses. But besides this the retort is made, look at your Pelargoniums, Dahlias, &c., which every year are produced in large numbers, and yet the greater portion of them ought never to have been sent out, being no better than those which were already in existence. I think the hit comes rather home, but "two wrongs never yet made a right," and there is, moreover, this great difference between the two: if I buy in a set of Pelargoniums, they take little room; in a few months I can see all about them, and discard or keep as I please. But it is a very different thing with Roses. A nurseryman buys his lot in the autumn; he has to prepare his stocks in pots ready for grafting. These pots have to be kept in a hothouse, and take up a great deal of room, and require a good deal of fuel. The space will be regulated according to his trade, of course, but, under any circumstances, it is an expensive process. These plants cannot be expected to give any reliable blooms, and it is almost eighteen months before he can positively decide, and then, perhaps, a large number of those about which he has taken so much pains and gone to so much expense would be consigned to the rubbish-heap. This, I think, it is that most severely taxes the patience and temper of Rose growers in England. The descriptions given are unreliable in too many cases; even if he goes by the name of the raiser that will not always avail, for it is a strange fact that some of those who have given us our best Roses have also weighted their vessel with some utterly worthless varieties. One would hardly think that the raiser of Charles Lefebvre would recommend Madame Leonie Giesse; and if he, one of the most reliable of French raisers, could do so, we may surely expect that others may make similar mistakes. While on this portion of my subject, one is tempted to ask, What is the standard of perfection recognised by French growers? In the "Journal des Roses" for February there is a list given of a hundred Roses, which a commission, formed by the Horticultural Society of the "Haute Garonne," has selected from those grown in the south-west of France, and amongst them I find the names of some which have been either banished from our lists or never known here: Christian Puttier, * Docteur Héron, Duchess of Sutherland, Duhamel Dumonceau, * Franciscue Barillot, * Général Duc d'Aumale, Gloire de Ducher, * Hortense Mignard, * La Motte Sanguin, Madame Angèle Despott, Madame Clarinde Leblond, * Madame Hunnebell, Mademoiselle Eugénie Wilhelm, Odrice Vital, Princesse Mathilde, and Triomphe de Toulouse; those marked having attained the highest

number of marks possible. Some of these I have never seen, and I very much question if they have ever been exhibited in England. In the same list, as well as in another in the April number on Lyons-raised Roses, I find Charles Lefebvre put down as having been sent out in 1871; this must be a mistake. I find it in Rose lists published in 1863, and, to the best of my belief, it was sent out in 1861.

But the chief cause of complaint, according to my correspondent, is that I have claimed credit for our English-raised Roses which is not due to them, for that it is a well-known fact that the greater portion of them are bought in France, rechristened, and sent out as English-raised Roses, and he gives me the following list, the first five of which he says are certainly French Roses, the others most likely so: Virgile, Firebrand, Duchess of Edinburgh, *Edipe*, Lord Beaconsfield, Princess Christian, Princess Beatrice, Star of Waltham, Reynolds Hole, and Sultan of Zanzibar.

Let me say in reply to this that there is evidently a mistake as to the two last on this list. I saw them in the seed-beds at Cheshunt, and know them to be English-raised Roses. Whatever may have been done in former years, it is tolerably clear that resource will not be had to this practice again to any extent; several hybridisers are at work. All know the parentage of the more recent English Roses, and can have no doubt as to what country claims the honour of introducing them, while those who do buy French Roses, such as Mr. Bennett, of Salisbury, openly proclaim their having done so. The practice of buying a foreign Rose and introducing it as if it were English is a very harmless proceeding,* and is only misleading in the event of prizes being offered for English-raised Roses, when, in some instances, it would be difficult to refuse a prize on this ground, sufficient evidence not being procurable on the point. It would be a very desirable matter to have a correct list of all really English-raised Roses, and as an instalment thereof I give the following:

Devoniensis, raised by Mr. Foster.

John Hopper, Mr. J. Berners, and Mrs. Ward, raised by Mr. Ward, of Ipswich.

Duke of Edinburgh, Beauty of Waltham, and Lord Clyde, raised by Messrs. Paul before the dissolution of partnership.

Princess Louise, Annie Laxton, Emily Laxton, Marchioness of Exeter, Mr. Laxton, and Charles Dawson, raised by Mr. Laxton, of Stamford.

Reynolds Hole, Cheshunt Hybrid, The Shah, W. Wilson Saunders, Sultan of Zanzibar, and Dr. Hooker, raised by Paul & Son, Cheshunt.

My correspondent doubts very much whether I am right in believing that English-raised Roses will be harder in constitution than French-raised kinds, and I think, perhaps, I was a little too decided in my opinion on this point, for, on thinking the matter over, I do most certainly call to mind instances to the contrary, and I remember one Rose of very great merit which obtained a first-class certificate, and was purchased for a considerable sum by one of our leading firms, but on growing and propagating it he found it so deficient in constitution that he threw it into the rubbish heap, while, on the other hand, some of the Lyons-raised Roses have a vigour of constitution one would hardly expect for the sunny south; it is then, I suppose, in this rather a matter of race than of birthplace, that seed saved from vigorous-growing Roses, whether at Lyons or Cheshunt, Brie or Slough, is likely to produce vigorous Roses. The question as to the origin of new Roses, is, perhaps, not so important now as it was a few years ago. English raisers are on their mettle, and, notwithstanding some drawbacks to their efforts, are not likely to allow themselves to be second in the race, and they must have seen that French raisers will not sell what they believe to be a really first-rate Rose; the *esprit de corps* is too strong for that, and they prefer having the honour of sending them out themselves. I do not think anything could have tempted the raisers of Charles Lefebvre, La France, Marie Baumann, or *Maréchal Niel* to have parted with them, and I find, as a matter of fact, that few of those Roses which have been bought in France and sent out in England hold a very high position in the estimation of rosarians. I am confirmed in this by an incident in my own experience.

Some years ago, it was reported that a Lyons raiser had succeeded in obtaining a yellow Perpetual Rose, and, as I was in France at the time, I was asked to go down to Lyons and try to procure it for a well-known caterer of novelties in horticulture. I went, but need not say it was an *ignis fatuus*; nothing of the kind was to be seen. In going through the Lyons Rose gardens, however, I chanced to see a new Rose of a very novel character, which I was desirous of obtaining for my friend. On my own responsibility, I offered what must have been a very tempting sum to anyone at all willing to do business for it. There was never for a

moment an atom of hesitation in the emphatic *non* with which my offer was met. "It is a grand acquisition, and I desire to have the honour of sending it out and having my name attached to it;" and so it was, and I believe, as long as Roses are cultivated, it will hold the place which I thought it merited.

There is still something to be done, and if only a raiser could get a yellow Charles Lefebvre, or a pure white Jules Margottin, what a fortune he would make! and why not? The strides which have been made should only lead us to look for further progress, and of this I am perfectly convinced that wherever any really good Rose is introduced no national jealousy, no insular pride will prevent the Rose growers of England from welcoming it and giving it all the honour due to it. In no country is there greater loyalty to the queen of flowers; but as our loyalty to our beloved Sovereign is naturally increased by the moral qualities of one who is a pattern to her subjects in all right ways, so our rosy royalty is naturally enhanced when we see it embodied in a flower of such surpassing excellence, as some of those which I have named.

DELTA.

NEGLECTED ROSES.

MANY a book has been written about Roses, and many more might and doubtless will, be published before Rose culture is half exhausted. To take the subject fairly from the commencement, let me begin by saying that of Roses we have no fewer than seventeen species indigenous to England. Exotic Roses, we read, were first planted here in 1622, and the Damask Rose was brought to us from Syria in 1573. Persia, China, the sunny vales of Southern Europe, and the rugged Alps have sent us specimens of this lovely flower. From the Isle of Bourbon and from America, too, Roses have made their way into our gardens and become in turn acclimatised, and later on parents of blossoms grander, larger, and more prized than themselves. But a word for the Brier and Dog Roses, sweet gardens of childhood! Who has not revelled in their odour and rejoiced in their delicate loveliness? These single native Roses are they which stamped, in 1377, the gold coin first struck by Edward III., and called the Rose noble; in architecture, they marked the Tudor epoch, and live yet in stone on many an arch as the Tudor Rose; it is the single Rose that blooms in heraldry the floral badge of England, and wreaths, with Shamrock and Thistle, the Royal Arms of the United Kingdom. The red and white Roses, innocent partizans of Lancaster and York, yet decorate many a cottage garden with rustic beauty; they have no place in Rose shows, indeed, but they are lovely notwithstanding; they last but a short summer's day, but they are sweeter scented than some of their finer relatives.

Modern history associates the Rose more particularly with three of the most unfortunate of queens, viz., Henrietta Maria of England, Marie Antoinette, and, lastly, the Empress Josephine, whose efforts in Rose culture have been perpetuated in the beautiful *Souvenir de la Malmaison* raised in Lyons, 1843. But every year produces some new claimants amongst the Rose family for horticultural honours, while every year also, at every Rose show, the judges must be puzzled to decide "which shall be fairest" where all are fair. Abler pens than mine have described the glories of *Maréchal Niel*, lingered on the perfections of *Niphetos*, dwelt on the charms of *Madame Lacharme*, and lovingly pictured the beauty of *La France*. Such Roses as these have many powerful friends; in truth to see them is to admire them, but those for whom I plead are lovely, too, a little old-fashioned, perhaps, but as we have gone back to coaches and mob caps, let us take one step back also to the flowers that charmed our forefathers.

First, then, where are the Pompon Roses, once, I am told, a feature at Rose shows? Where is that charming little *Rose de Meaux* (that surely was the Rose in the nursery tale, and which fell from the mouth of the good girl who befriended the fairy)? and why is it never represented at exhibitions? Then as regards the lovely Scotch Roses, exquisite in perfume, very cups of attar, how rarely do we see them now, except, indeed, in old-fashioned gardens. The Austrian Brier is never mentioned among Roses, though it would be hard to find another of the same colour. As for the *Macartney Rose* (*Rosa bracteata*), it seems unknown, though in bud and blossom it is most handsome—worthy even a poet's praise or a painter's pencil. And, lastly, who now cultivates that loveliest of damask (?) Roses, the *Rose Céleste*, of the softest rosy-white, the colour so delicate, that it might form a fitting wreath for Aurora? This

Rose is fairest when 'tis budding new.

Its perfect beauty thrown into relief by the glaucous green of the calyx and foliage; expanded, it is true the flower is too single for a connoisseur to admire, but to those who raise new Roses from seed, the colour of this, combined with form and substance of some fuller variety, would prove a *me plus ultra* of beauty. Will some knight of the Rose champion the cause of these neglected Roses?—blossoms

* My correspondent says, No; it is dishonest, as it would be if, as he says, I buy an English racehorse, run him in France, give him a French name, and say he is a French horse.

as far as those which suggested the romance of the Rose, or inspired the poets of our own day with endless verses in their honour. But where can the pen stop which writes of this queenly flower?

C. R.

TREATMENT OF GRAFTED ROSES.

IN an article of mine which appeared in THE GARDEN about four months ago, entitled, "Conditions under which Grafting is Beneficial," I recorded some observations on the growth of different kinds of Roses on the Brier stock, stating, among other things, that in the case of weakly-growing Roses I did not think we utilised the stock to the best advantage by repressing its growth entirely, in the belief that by so doing we directed its energies into the Rose budded upon it, and I suggested that, in order to encourage weakly plants, it would be a good plan to encourage a partial growth of the stock as well—that, instead of rubbing off all suckers that push near the graft, they might be left and encouraged to some extent. When I wrote to this effect in December, I had no idea that my suggestions had already been put in practice, and with the very results predicted by me. According to the "Revue Horticole," M. Charbon has found that weak Roses budded upon strong stocks thrive best when the stock is permitted to make a certain amount of growth as well, and that when the shoots of the latter are rubbed off the graft loses its vitality to a great extent. M. Charbon thinks the growth of the stock promotes the vigour of the graft by drawing the sap up to it, that is, when the growth on the stock is above the graft. This may be, but, as I stated in THE GARDEN before, I think it will be found of no consequence whether the growth of the stock be permitted above or below the graft, so long as it is pretty near it, and it is usually easier to promote growths under the graft than above it. There is only one point in M. Charbon's theory on the subject which does not fit exactly. In one place he attributes the failure of weakly-growing Roses on strong stocks to an over supply or surfeit of sap; and in another place he attributes the vigour of the graft to the supply of sap pumped up by the growth of the stock, an apparent contradiction. The first supposition, I imagine, is wrong, and the last right. It has always appeared to me that a weak graft had not the power to pump up a sufficiency of sap for its own wants. Be this as it may, the question is an important one in relation to grafting generally, and I would be glad to hear the opinion of Rose growers and others on the subject.

In the case of Vines I have for a good many years acted on the idea here indicated, always either permitting a limb of the stock to grow also, or putting the graft on half-way up the rafter, thus giving the graft the benefit of the leafage of the stock to a large extent. I do not go so far as to say, as some have done, that a stock is ever wholly controlled by the graft, or that it in time becomes simply what the graft makes it when its own growth has been constantly suppressed, but I believe that putting a weak graft upon a vigorous stock, and encouraging the one and suppressing the other, is a pretty sure way of enfeebling both, if not, in the case of the Rose, of killing them outright. It is a fact at all events which has been often enough verified, I should suppose, that when weakly Roses on the Brier stock die, not being killed by frost, the stock dies too, unless it has been allowed to make a partial growth of its own. It is not a little singular that Lindley, who held that root vigour depended largely upon a healthy top growth, should have overlooked this fact in relation to grafting, considering how fully he has treated the subject, nor does the idea ever seem to have occurred to those who have taken up the subject of vegetable physiology where Lindley seems to have left it.

I may be allowed to mention that some years ago I pointed out similar facts to those recorded above in THE GARDEN and elsewhere in relation to weak-growing and variegated plants, stating that so long as healthy or green branches were preserved on the plant, whatever it might be, weak or perfectly-blanching leaves and limbs thrived, but that they perished soon after the former were removed.

J. S. W.

EFFECTS OF FROST ON ROSES.

INDREASAT we have had as severe a winter here on the Yorkshire uplands as anywhere, and perhaps a longer one than has been experienced in some parts. The snow began falling about November 6, and it was scarcely ever off the ground till the beginning of March; since then, too, we have had more snow and some frosts. I had, consequently, much anxiety as regards our Roses, and more especially for about 200 plants of good kinds that we had planted just before the snow fell. In looking over them a few days ago, however, I found there were not above three or four of the whole lot injured, and they were weakly ones to begin with. All are on the Brier stock, and consist of standards of all sizes. Whether they will yet show signs of injury I cannot, of course, say, but the buds look promising at present. I attribute their safety almost solely to the fact that as soon as they were planted, owing to the frost and snow setting in, I had them all thickly protected with stable litter over the roots and up the stems 6 in. or 9 in. My experience is that without such protection autumn-planted Roses in such winters as that which we have just experienced have little chance of surviving. Another thing which accelerates the action of the frost is autumn pruning. Pruned Roses always suffer most severely in hard winters. Pruning therefore should be delayed till spring, and, as a precaution against frost, newly planted Rose borders and beds should always be covered deeply with leaves or litter.

J. S. W.

Marechal Niel Rose.—The most satisfactory way of growing this beautiful Rose is as a roof climber, where it can be allowed to extend its branches as it pleases. We have two plants of it covering

New Bamboo Shading.

the roof of a large house, from which hundreds of beautiful blossoms have been cut, and yet buds in various stages of development still remain. As regards pruning, we merely cut out weakly or worn-out shoots after flowering, and train in vigorous young growths at full length. These produce a great abundance of fine flowers. Beautiful as this Rose is, it is not adapted for a standard, as close pruning destroys nearly all chances of bloom, but anyone giving it a trial under glass will be well rewarded for any care that may be bestowed upon it.—J. GROOM.

BAMBOO SHADING.

WE have received from the New Plant and Bulb Company, Colchester, the annexed illustration showing the way in which this new shading, to which we have previously alluded, is used, and also the way it is made. It consists of light Bamboo rods, a little stouter and stronger than Reeds, varying from 3-16ths to 3-8ths of an inch in diameter, the smaller size alternating with the larger size, while stouter rods, 3 in. thick, are interspersed here and there to strengthen the whole, which is interlaced about every 9 in. apart with a coarse, strong, and durable twine made from the outer husk of the Cocoa-nut. These mats are made in widths of from 8 ft. to 10 ft., and of any length required. The rods, when put up, run horizontally; the mat being perfectly flexible and very light, can, when in use, be easily rolled up by a cord fastened above, passing downward and beneath the mat, round the roller of the mat at its lower margin, then up again to the top, whence passing over a screw pulley, the cord descends again to the bottom of the mat, where it is within reach of the manipulator.

A shows the Bamboo mat partially unrolled, with box at top complete for its protection.

B—cover of box removed to show the mat rolled up when not in use.

CC—bearers upon which the mat is supported 10 in. or 12 in. above the level of the glass.

DD—screw pulleys round which the cords run to pull up the mat.

In order to let down the shading, loosen the cords which have been fastened to the hooks placed in the front wall below the glass; the mats will then fall down by their own weight. In rolling up again, see that the cord hangs straight down the middle of the mat, then pull up steadily and fasten. The mats are fastened above to

five or six staples, firmly driven in at the bottom of the box cover inside, by tying to them the thick Bamboo at the end of the mat with strong twine. It is as well to have a wooden roller tied by string to the lower end of the mat to make it roll up more easily.

TREES, SHRUBS, AND WOODLANDS.

HEDGES AND SCREENS.

WELL-GROWN and neatly-kept hedges add much to the general good appearance of a garden, and when, as is frequently the case, they constitute the sole boundaries, no pains should be spared either in forming them or in maintaining them in good condition. The occupiers of small gardens cannot often indulge in the luxury of walls, but they may, by means of hedges and screens, provide for themselves a considerable amount of shelter. The sunny side of an evergreen, or even of a good thick Quickset, hedge may be utilised for forwarding early vegetables, and the north side would prove equally useful for sheltering pot plants from the hot sun, or for planting out Primroses, Violets, and other shade-loving subjects during the warm summer months. Hedges often present an unsightly appearance through either having been badly planted or neglected at some period of their growth. If the ground is trenched and plenty of manure put into it a free, healthy growth and a handsome fence will be the result. The reverse of this treatment is, however, too often practised; the plants are set in poor soil, they become stunted, and are years in obtaining the desired dimensions. Thorn and Holly may be considered the most serviceable plants for boundary fences, and when well planted and carefully tended, they will serve even more effectually than walls to protect a garden against intruders. If utility and cheapness be alone to be held in view Thorn must be chosen. It may be purchased at a cheap rate, will thrive in any well-enriched soil, and, if generously treated, will form a dense impenetrable fence. If allowed to run up to the height of 15 ft. or 20 ft., it forms in bleak, exposed districts an admirable protection to fruit tree plantations. In the high-lying and sea-blown fruit-growing districts of the Isle of Thanet it is frequently thus employed. If planted in well-enriched soil at the same time at which the fruit plantation is formed, it will, by the time that the trees come into bearing, effectually screen them from rough winds. Quickset may be planted at any time during winter and early in spring, but the best time is undoubtedly as soon as the leaf has fallen; the roots are then fairly active and immediately establish themselves in the soil; they thus get much better hold, and are enabled to start more strongly into growth the following season than when the planting is deferred until a later period. After the ground has been properly stirred and manured it should be levelled; a line should then be stretched upon it from end to end; then commence at one end, taking out a spit of soil and cutting down perpendicularly by the line; place the young Quickset so that the roots are evenly spread upon the soil and the stem hard against the line; fill in with earth and tread firmly. Work through the whole distance in this manner, setting the plants about 1 ft. apart. It is not advisable to cut the plants back the first season, but the second year they should be pruned in to about 18 in. from the ground; they will then, having got thoroughly established, break and grow very strongly the following season. Cleanliness during the summer months is of great importance; not a weed should be allowed to encroach upon the plants, and if a mulch of rotten manure can be afforded them, it will exercise a great influence upon their growth. It must never be forgotten that a hedge is of no real practical value if it be not so closely furnished at the bottom as to be perfectly animal proof. This desired result can only be attained by cutting it back rather closely for several successive seasons, thereby favouring the development of the lower portion, which should, in every case, be maintained somewhat thicker than the upper part. A perfect Quickset hedge should slope gradually from the ground upwards, and throughout its entire length it should be so close that the hand could not be passed through it.

Old hedges that have, through neglect or ill-usage, become unsightly, may be, to a certain extent, renovated. The best way is, undoubtedly, to grub them up, heavily manuring the soil and planting afresh; but such a process entails more labour and expense than many are willing to incur; others, again, object to laying their gardens open for the period of time necessary to bring the new hedge up to the required height. It frequently happens that Couch and, in many districts, Bindweed have taken possession of the soil, and have starved the Quick into a state of debility, and denuded the bottom of foliage. The only remedy in such a case is to trench down on one side of the hedge, extracting all the roots of these weeds, working in a liberal application of manure, and allowing the Quick to grow unrestricted for one season. This treatment will induce a

renewed root-action, and the following year clipping may again be practised, keeping the sides closely cut in, but allowing the terminal shoots to grow until the autumn, when they may be cut back again. By following up this system for several successive seasons, a great improvement will be perceivable; and if, in addition, some free-growing Holly or Privet be introduced at intervals, they will, in time, completely refurbish the lower portion.

For beauty, combined with utility, no known plant can rival the Holly; it is even more impenetrable than Thorn, and its evergreen character renders it pleasant to the eye in winter. Holly will thrive fairly well in almost any soil, if well drained, but it prefers a sandy loam, in which it attains a high degree of luxuriance. On high-lying and dry sandy or gravelly soils it appears to be quite at home, and some of the best hedges which I have ever seen were on land of this description. At Otlands, near Weybridge, on very poor, but perfectly drained, land there are some magnificent examples of Holly hedges; in fact, they might be termed Holly walls, they are so high and thick. Holly is commonly reputed to be slow as regards growth, and many are deterred from planting it, fearing that a long period must elapse before an efficient fence can be formed. It is true that in poor soils young plants will often require years before they increase much in size, but if planted in well-manured and deeply-trenched ground, they shoot up with great rapidity. Holly cannot be relied on to live if planted between the middle of October and the end of March. It must be moved before the roots have gone to rest, or at the moment when they are beginning to move. In September or April not 2 per cent. will perish. A Holly hedge may be made to assume a very ornamental appearance if a terminal shoot be allowed to run up at intervals, and be either grafted or budded with the golden or silver-leaved varieties. When the variegated kinds have attained sufficient dimensions to display themselves, they produce an extremely good effect, and impart an air of richness and cheerfulness to the garden itself. From the fact of the Holly being known to prefer dry situations, it is generally considered necessary to plant it somewhat above the level of the soil; but unless the locality be very low and damp, there is no need to incur this extra amount of labour. If 2½ ft. of well-drained soil can be secured it will succeed as well as when planted on a raised mound. The directions given for Quick planting will apply of the Holly, except that the distance between the plants will naturally be determined by their size. Some, to whom expense is no object, will prefer to employ large plants; but, in a general way, I would recommend young thrifty two-year-old seedlings, which often establish themselves better and outgrow older plants.

Privet may be employed either alone or mixed with Thorn. It forms a neat hedge and is evergreen, but it makes an enormous amount of surface roots, which entirely rob the soil around it of nourishment and moisture. Where Privet is employed the path should be next to it, or the ground must be trenched down every two years and the roots cut off. Privet is more suitable for separating plots of land or dividing the pleasure grounds from the vegetable garden than for forming boundary fences. It makes a compact hedge when kept down to about 4 ft., but it is hardly robust enough to be of service where a strong, impervious 7-ft. fence is necessary.

Yew is sometimes employed as a fence with good effect. It succeeds well in some soils, but it cannot be considered a suitable subject for general purposes, as it is easily penetrated, and is apt, after attaining a good size, to die off in hot summers; moreover, owing to the danger incurred by cattle browsing on it, it cannot be employed in many situations. A purpose for which it is well adapted is forming screens in the pleasure ground, or where sheltered spots are needed in plant culture. It makes noble walls of verdure, and when allowed to run up some 10 ft., and kept closely clipped, both the sunny and shady sides may be profitably utilised. In old gardens Yew screens are often seen, but other quick-growing Conifers have now supplanted Yew for this purpose.

Leafy walls, if I may be allowed to use that term, are preferable for some purposes to brick walls, especially in summer, as they not only afford a cool, shady retreat, but they allow air to constantly percolate through them, which cannot but prove beneficial to such plants as may be placed under their shelter. Thuja Lobbi and Waxed are two good subjects for this purpose; the former grows quickly, and the latter presents a very close and neat appearance. Beech is sometimes used in nursery grounds for protecting choice shrubs, and it is very serviceable for that purpose. In bleak situations it forms an efficient shelter for the best varieties of Rhododendrons and Chinese Azaleas, which are apt to get beaten about during the flowering season if too much exposed to rough winds. Where plant-growing is conducted on a large scale, screens having various aspects should be specially designed, a command of which and of shelter often proves of the greatest service, and considerably facilitates the labour of the grower. J. C. B.

THE BUTCHER'S BROOMS.

The five known kinds of Butcher's Broom are decidedly ornamental, as well as curious, plants, and are well worth a place in gardens. With one exception, they are hardy, and in a state of Nature are distributed throughout Europe, temperate Asia, and North Africa. All, except the one placed last in the list given below, are also of great use in planting under the drip and shade of trees where but few other evergreens would exist. The most ready method of propagation is by division of the roots. The true leaves are minute, scale-like bodies, very inconspicuous, and from the axils of these spring the flattened, leaf-like branches, which assume the appearance and perform the functions of real leaves; these branches are technically called cladodes.

The Common Butcher's Broom (*Ruscus aculeatus*), represented by the accompanying woodcut, is by far the best known of the group. It is a true native of England, where it is found in

Common Butcher's Broom in Flower and Fruit.

coppices and woods from Suffolk and Glamorgan southwards, being naturalised in Scotland and Ireland. The small greenish flowers, which appear in April, are borne on the rigid, spiny, somewhat egg-shaped cladodes, and are succeeded by bright red berries about the size of Peas. This dwarf, dense, much-branched shrub rarely attains a greater height than 2 ft.; its thick, white, twining roots strike deep into the ground, and when once established, even under apparently very adverse conditions, it grows freely.

The Alexandrian Laurel (*Ruscus racemosus*) is an elegant shrub with glossy, dark green, lance-shaped cladodes, larger than those of the common Butcher's Broom, the inflorescence of which is very different, the flowers in that being borne singly on the cladodes, whilst in the Alexandrian Laurel the blossoms are produced in terminal racemes. The habit, too, of this plant is not nearly so dense as that of the last-named, but it grows to about the same height. A native of Portugal.

The Broad-leaved Butcher's Broom (*Ruscus Hypophyllum*) is a very dwarf kind from the South of Europe, with

lance-shaped cladodes 2 in. or more in length, and nearly an inch in width. The blossoms are—as implied by the name—produced from the under surface of the cladodes.

The Double-leaved Butcher's Broom (*Ruscus Hypoglossum*) also comes from the same region as the preceding sort, and is very similar in general appearance, size, &c., but it has the flowers on the upper surface of the cladodes, each flower having a smaller cladode overhanging it.

The Great Alexandrian Laurel (*Ruscus androgynus*) is the only member of the genus which will not flourish in the open air. It is a very striking greenhouse climber, requiring ample space for its full development. There are two magnificent examples at the Crystal Palace, where portions of the galleries at the south end of the building are draped with its beautiful evergreen covering. The long shoots, some of which are 40 ft. or more in height, last for several years in full vigour and beauty, and as they die off others are produced from the root. At Kew, too, surrounding one of the staircases of the gallery in the temperate house, there is also a fine plant. Nothing could surpass in these positions the beauty of the specimens we have named. The young thick shoots grow up in a single season 30 ft. or more, and then commence to give off branches down to the very ground. These branches are from 2 ft. to 2½ ft. long, and have much the appearance of large pinnate leaves; the blossoms are borne in three round the edges of the cladodes. A native of Madeira and the Canary Islands. G.

WOODLAND WORK FOR MAY.

DURING the present month the forester's chief aim should be to secure his Oak bark, and to prepare it for delivery to the tanner in the best possible condition. As the bark season is nearly a fortnight later than last year, it will probably prove a short one, for if warm weather sets in the trees will rush rapidly into full leaf, after which the stripping will be difficult, and the loss of weight will be considerable. For the time, therefore, all other operations in the woodlands should give place to this. At present very low prices are offered by buyers, not more than £4 per ton in the woods; but neither the stocks on hand nor the quantities which are likely to be offered during the season warrant the acceptance of such a price, and if vendors remain firm prices must shortly improve.

Every possible exertion should now be made to clear away from the coppice all poles, faggots, and brushwood, and to take up whatever has been laid upon the stools to facilitate carriage from the falls. No horses should be allowed to remain unmuzzled in the falls after the appearance of the young shoots, and to ensure an early clearance of the produce, the conditions of sale should be strictly enforced. Even with the most careful supervision a great deal of mischief is done to the cut stools in coppices by the feet of horses and the wheels of heavy carriages where the produce is not carried to the sides of brushed roads for loading. To avoid unnecessary traffic in the falls the stripped bark should be staged near the sides of clearance roads, and the fallen trees, together with the tops, should also be speedily removed. Injured stools may still be thinned off smoothly and evenly with the alze, and where it is customary to thin out the shoots in falls made two years ago, this operation should now be performed. By selecting from four to six strong shoots, according to the strength of the stool, and removing all the others, a much more valuable crop of poles will be grown than can be obtained by allowing all the shoots to grow on together until the period of falling. This practice is remunerative under all circumstances, and where the produce of coppice bark is a principal object it is indispensable.

Wherever plants of a large size have during the past season been put out into the woodlands, these will now require going over and treading up. Evergreens in exposed situations may also require staking and tying. Wherever it is now considered advisable to remove evergreens of large size, these should remain out of the ground as short a time as possible; and such as have to be carried a considerable distance should either have a ball of earth attached, or else their roots should be well puddled as soon as the plants are taken out of the ground. With careful removal and one copious watering, such plants may be considered safe.

In the nursery finish the sowing of Coniferous seeds, and protect those young plants which are just appearing above ground from the ravages of birds and from destruction by late frosts. The transplanting of Coniferous seedlings should be finished as soon as possible, and all seed-beds should be carefully weeded by hand before the weeds gain sufficient hold of the ground to cause the disturbance of the young plants by their removal. Wherever the seed-beds have become battered, and the surface hardened by the late heavy rains, a careful rolling with a light spiked wooden roller is a much safer plan of loosening the surface than raking. The hoe will now require to be kept constantly going between the rows of young plants, and

the frequent use of the fork among those of larger size will greatly promote the growth of fibrous roots. The beds from which strong deciduous plants have been taken should now receive a good stirring with the fork, and have all the broken roots removed from them, preparatory to the planting of the green crops, which, with a liberal dressing of manure, should precede the next tree crop.

Now that there is little danger of sharp frosts, the trimming of evergreen hedges, such as Box and Holly, may be at once completed. When this is done too early in the season, the frost is apt to whiten and render unsightly the cut leaves and branches. Wherever labourers are plentiful, draining, enclosing, and road-making for future nurseries and plantations may be proceeded with; composts may also be made, or turned over and mixed with lime, for future use; hedges may be cleaned, grafts attended to, and have the clay renewed where required. Grass seeds may also still be sown in wood-rides, or in situations where they may be required to increase the cover for game. The best results will be obtained upon land which, after a thorough cultivation, is well rolled down before the seeds are sown and lightly bush-harrowed afterwards. The lighter Grass seeds are covered the better. A. J. BURROWS.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Aucuba Berries.—Mr. Tillett's experience seems very "exceptional," for with us this season many of the plants are quite loaded with berries and are exceedingly attractive, and the plants were treated in all respects as "J. G." (p. 289) recommends. Since reading Mr. Tillett's remarks, I had the curiosity to measure the distance between a male and female plant, and found it to be 48 ft.; yet the female plant was well covered with berries, proving that a few male plants thinly dispersed over a large tract of ground are sufficient. I have long discarded the practice of artificial fertilization, finding results without it equally satisfactory. The green-leaved varieties bear much larger cluster of berries than the ordinary *Aucuba japonica*, and on them the red fruit is shown off to better advantage against the self-coloured leaves. Is Mr. Tillett sure he has got male plants? If so, I can only account for his failure by the pollen having been destroyed with spring frosts before it became matured. In such a case I would recommend Mr. Tillett to put a few Spruce branches over his male plants this season—just enough to protect them when in flower.—A. H. R.

Ribes sanguineum.—This beautiful flowering Currant, when planted in shrubby borders, should occupy an open position, where it can get full sunlight and exposure, so that the growth may become dwarf and floriferous, for, if planted in half shady positions, very little of its best effects are visible, and its wood does not get ripened. We have at present some bushes of it that well deserve the name of Burning Bush, for being planted on the outskirts of clumps in the park, they form brilliant spots of colour that are effective several hundred yards off. From the exposed positions which they occupy on breezy hillsides the growth is short and stubby, and they flower so exceptionally abundant that they look one solid mass of glowing red.—J. GROOM, *Linton*.

Pinus insignis.—In answer to recent inquiries for rates of growth of this Pine, I may quote two specimens here, in sheltered situations, about a mile from the shores of the stormy Atlantic. One was planted in 1842, and is now more than 70 ft. high; it girthed 2 ft. 6 in. at 3 ft. from ground in 1856, and now girths 9 ft. 3 in. at the same point. The other, planted in 1856, is now 50 ft. high, girths 7 ft. 6 in. at 3 ft. in height, and has a well-balanced mass of dense foliage, averaging 40 ft. across from tip to tip. Each plant was a nursery seedling. The fertile soil of Ireland will probably produce more rapid growth than either of these specimens exhibit, but in our poorer soil they prove that the climate suits them. No Pine that has been tried here can approach *insignis* for vigour, beauty, or shelter, and not one of the many hundreds that I have shown any trace of the severity of the past trying season, which has been so destructive to half-hardy plants.—J. J. ROGERS, *Penrose, Helston*.

The Sweet-scented Shrub.—Every one knows the Sweet-scented Shrub (*Calycanthus*). As children we have doubtless rolled its chocolate-coloured flowers in our handkerchiefs and inhaled their sweet odour, and that of its camphor-scented wood; but do we realise the plant's full excellence? It has become so common, that, like all familiar things, it has failed, perhaps, with time to retain its proper hold on our regard. There are several varieties, the best known of which are *C. floridus* and *C. levigatus*. Then there is *C. macrophyllus* of the Pacific coast, which is not quite hardy, and several others of less value. The kind, however, that is best known to us, and which is at the same time the best plant, is *C. floridus*. It has

the largest flowers and leaves, and is of unquestioned hardiness and vigour, well suited in every sense to do good service on the lawn. It may not have the high degree of excellence possessed by some other shrubs that could be named, but its foliage is rich and shining, quite noteworthy in general character. Its curious reddish-brown or purplish flowers, moreover, form a feature possessing much interest. The *Calycanthus* has been thought in the past a somewhat difficult plant to grow, but it is really not specially difficult to propagate from root cuttings. Seed would, of course, produce it, but seed is not easily obtainable, and in other ways affords a less ready method of propagation. Altogether, the Sweet-scented Shrub (*C. floridus*) is a fine old hardy plant that we cannot afford to neglect.

The Siberian Stone Pine (*Pinus Cembra* *Mandschurica*).—In Italy we have the Stone Pine (*Pinus Pinea*), somewhat umbrella-shaped in contour; Switzerland and Northern Europe contribute the Swiss Stone Pine (*Pinus Cembra helvetica*); and Siberia the Siberian Stone Pine (*Pinus Cembra Mandschurica*), the tree which we specially wish to note. The Italian Stone Pine, though picturesque, is not hardy in our climate, and so I pass by it without further comment. Swiss Stone Pines are more or less common, and always admired on the lawn. Their excellences have received a fair degree of attention, although no more than they deserve; but I hardly think the same can be said of the Siberian Stone Pine (*Pinus Mandschurica*). Yet it is altogether a more noteworthy tree. The leaves are stronger and massed together in a more effective way. Broader contours and greater height also give it more imposing qualities. It has, indeed, according to Gordon, been known to grow 100 ft. in height. Pines, in their breadth and masses and drooping grace of clustered needles, are, in some sense, the Palms of the north, and among Pines few are more effective than the Siberian Stone Pine, with its great cones of extraordinary length. These reddish-brown cones of such unusual size are very effective, contrasting in autumn with the long, heavy, hanging Pine needles.—"Rural New Yorker."

NOTES OF THE WEEK.

Successful Growth of Alpine Flowers.—We notice *Gentiana verna* thriving as freely on an exposed border in the Rev. Mr. Ewbank's garden at Ryde as the common *Gentianella* (*G. acaulis*) frequently does in "old-fashioned gardens," where it gets a chance. We have long been convinced that *Gentiana verna* would thrive freely on the level ground, whereas it generally perishes on rock gardens of the common type and in frames. In the same garden a still more delicate Alpine flower (*Androsace carnea*), also on a border, is now a cushion of green decked with pink blossoms, the plant being surrounded and in a way protected from accident by a few half-buried bits of sandstone. Near it likewise grows the rare and fragile little *Petrocallis pyrenaica*—very seldom seen, even in botanic gardens where Alpine plants are grown—also a mass of lilac blossoms. Mr. Ewbank protects his dwarf and delicate plants very successfully by placing a ring of perforated zinc around them, which keeps off the slugs, creatures which, if allowed their own way, frequently graze down dwarf Alpine plants in a single night. The climate is favourable, though often too hot in summer for Alpine plants.

The Crimson and Yellow Alpine Polygala.—This brilliant Alpine plant, figured in *THE GARDEN* some time ago, is one of the greatest gains among hardy plants introduced for years into our gardens. We say so much, judging from a small but healthy specimen of it now flowering in Mr. Ewbank's garden, near Ryde. The plant we figured it from was, no doubt, from being imperfectly established, rather in a weakly condition, though its beauty was so manifest that we did not hesitate about devoting a coloured plate to it. But this sturdy little plant, in the open air, is far finer—so beautiful, indeed, that an enthusiast would not hesitate to build a rock garden for it, if that were necessary, which it is not, Mr. Ewbank's plant growing on a gently-raised bank. The flowers are handsomer than those of any of the greenhouse *Polygalas*, seated on a sturdy evergreen, $\frac{1}{2}$ in. high, every flower being quite "true" in its rich colouring. We note this last quality in reference to the supposition that the plant was but a discoloured variety of *Polygala Chamebuxus*.

Tulip Cultivation in Holland.—The Dutch official trade returns show that the exports of flower bulbs during the sixteen years from 1861 to the end of 1876 amounted in value to 19,640,000 Dutch florins (about £1,636,000), or an annual average of over £100,000. It appears that the value has been annually rising; thus the export for 1876 is set down at 1,666,000 florins (nearly £139,000). According to the latest survey the land devoted to rearing bulbs of Tulips, Hyacinths, and similar flowers amounts to 240 hectares, or

nearly 600 acres. Of these about 10 acres are in the neighbourhood of Egmout, about 90 round Velsen, while the remaining 500 acres are in the neighbourhood of Haarlem, Schoten, Bloemendaal, and Heemstede. But besides these special localities, where the cultivation of the bulb is carried out on a large scale, there are innumerable small patches scattered all over the country where Tulip and Hyacinth bulbs are reared with great care and success.

Azolla pinnata.—This extremely interesting flowerless plant may not inaptly be named the Floating Selaginella, to the smaller-growing kinds of which it bears a remarkable resemblance. Each plant is about $\frac{1}{2}$ in. in diameter, of irregular outline, and emits a tuft of thread-like roots from the under surface. The upper surface is bright green, except the edges, which are tinged with a reddish hue, and the whole, when minutely examined, sparkles with crystalline brightness. For small indoor aquaria it would be a charming acquisition, as it appears to be indifferent as to the precise temperature of the water on which it floats; it may be seen flourishing in the Victoria tank at Kew, and also in inverted bell-glasses in a cool house. Like many other aquatic it has a very wide geographical range, as it inhabits the pools of the warm temperate parts of the Northern Hemisphere as well as those of the Southern.—W. G.

New Muscari.—In "Notes from Kew" last week allusion was made to a novelty under the name of *M. Pinardi*, but which is now proved to be *M. armeniacum* (syn., *Botryanthus armeniacus*). It is, undoubtedly, the finest of all the kinds in cultivation; its dense racemes of blossom are nearly 3 in. long when fully grown, and their colour is a clear cerulean blue before expansion, deepening into a rich indigo tint, with the pure white teeth quite obliterated; it is also very floriferous, as the Kew plant produced three spikes in quick succession from each bulb. It is evidently allied to *M. Heldreichii*, but differs from it in having broader and much longer leaves; from its specific name we may infer that it comes from Armenia. *M. Pinardi* is also a new plant, but it belongs to the other section of the genus, viz., the *Leopoldias*, in which the racemes are long, each being terminated by a conspicuous tuft of barren flowers.—W. G.

Large Camellia.—Close to the old mansion belonging to the Earl of Kenmare, at Killarney, is growing a magnificent specimen of the old *Camellia reticulata*. It is about 45 ft. in circumference, though but some 5 ft. or 6 ft. in height. When we saw it in the early part of this month, says the "Gardener's Record," the flower buds could be counted by the thousand, many of them having just commenced to open. It is in the most vigorous health possible, at its dark green foliage testifies, and the past severe winter does not appear to have injured it in the least, though the only protection afforded was a piece of old canvas placed over it when the frost was most intense.

Gloneria jasminiflora.—At first sight this handsome new plant might easily be mistaken for a Jasmine. Its habit of growth is erect and bushy, and it has ovate leaves 3 in. long arranged in opposite pairs. The clusters of blossoms terminate the branches, and consist of about a dozen in number, each having a narrow tube $\frac{1}{2}$ in. long, and a four-cleft corolla 3 in. across. The whole flower is of snowy whiteness, and the outside of the blossoms are covered with white down. Some trade labels class this *Gloneria* with stove plants, but most probably a greenhouse temperature will be found most congenial to it. It produces its blossoms during the winter and spring months.—W. G.

The Blue Polyanthus (*Primula elatior cerulea*).—This old garden favourite, well-nigh lost to cultivation, is flourishing on the rocky at Kew and producing blooms in profusion, but they are slaty coloured rather than true blue. They are, however, the nearest approach to blue that we have in the *Polyanthus*, and on that account the variety is desirable. Another beautiful plant belonging to the same charming family, and a very free flowerer, is *Primrose Golden Prince*, which bears the deepest yellow flowers of any we know of; it has been the admiration of all who have seen it.—W.

Alpine Primroses.—Amongst the numerous kinds of Alpine plants that flower at this season of the year Alpine *Primulas* are, perhaps, the most conspicuous. Of these we noticed the following in bloom the other day in the York Nurseries, viz., *Primula latifolia*, *viscosa*, *villosa*, *Allioni*, *marginata*, and its large-flowered variety, *tyrolensis*, *Venzoi*, *pubescens*, *nivalis*, *purpurea*, *pulcherrima*, *rhaticola*, *Floerkeana*, *spectabilis*, *auriculata marginata*, *Babissiana*, *glaucescens*, *rosea* (nearly over), *ciliata*, *Dinyana*, *graevelensis*, and multi-caps.—P.

Wellingtonia Wood.—We have, says Dr. Woodman, of the Exeter Nurseries, sent out all our Easter flowers this season in boxes made from the wood of the *Wellingtonia gigantea*, grown by ourselves. We had occasion to cut down a grove of these trees to make room for other plants, so we utilised the timber, which is like Larch, but has a vein of pink running through it.

The American Dog's-tooth Violet.—By this we mean the rich yellow *Erythronium americanum* so common in the Atlantic States, and not the paler and, as we think, poorer yellow kinds lately brought from California. *E. americanum* is in flower now, and very beautiful it is, so much so that it is surprising it is not as much grown as the European Dog's-tooth Violet (*E. Dens-canis*). *E. americanum* would not appear to thrive on all soils, for we fancy it often fails to flower where it seems to grow fairly well.

Artisans' Plant Show.—The show of this kind held in the gardens at South Kensington last year having been attended by as many as 16,000 of the artisan and labouring classes, there will be a similar exhibition there on Whit Monday, June 2. In order to place this source of enjoyment within the means of the poor, 2d. only is to be charged for admission; and as the cost of the show is very great, it is hoped that contributions will again be made to the prize list.

The Marnock Portrait.—Mr. T. B. Wigram's portrait of Mr. Robert Marnock has been accepted at the Royal Academy, and is well hung in the centre of the Lecture Room. The portrait is considered a most excellent one, both by artists and those who know Mr. Marnock. Our readers will remember that this is a presentation portrait offered to Mr. Marnock by a number of admirers of his work as a landscape gardener.

Odontoglossum vexillarium.—There is now a grand display of this *Odontoglossum* in Mr. Bull's nursery, King's Road, Chelsea. It consists of 300 expanded flowers, some of them the highest and richest coloured varieties that have ever yet been introduced.

Botanical Diagrams.—Dr. Arnold Dodel-Port is publishing at Zurich a series of botanical and physiological diagrams, which will be useful in schools and for botanical lecturers. Specimens of them may be seen at the Linnean Society.

ANSWERS TO CORRESPONDENTS.

Hyacinth Blooms Severed from the Bulb.—Along with this I enclose two flower-stems of *Hyacinth* grown in a cold air, and should be obliged if you or any of your readers could tell me whether they have been severed from the bulb by slugs or other vermin. I also send the bulb and foliage of one in case it may grow close to the other, and only the blue (out of a large number of them) have been thus treated. The bulbs seem to be sound, even after the hard winter which we have had, and are throwing up very large spikes of flowers where untouch. They are growing in a bed made up two years ago of road scrapings, turf, and leaf-mould, which has since been liberally manured, and has grown bulbous as well as bedding-out plants each year since. All the sound flower-spikes are now about 3 in. clear of the ground, and seem to be out of danger. As all the injured ones seem to have been cut out about the same time and height, and as they rested on the foliage in a natural position, they were not noticed until the sound ones began to distance them in growth. The bulbs came from Holland direct, and the three colours are furnished respectively by Van Thuyll, Queen Victoria, and Robert Steiger.—L. J. B. [The flower-spikes sent look as if they had been eaten off by slugs.]

Greenhouse Shading.—What is the best preparation for "muffing" the glass of greenhouses (outside) such as will not be washed off by the action of the weather, and which can be washed or rubbed off at the end of the summer? I have been using whitening and milk, but find it is washed off sometimes by heavy rains.—SUBSCRIBER. [A little size added to the whitening and milk will cause them to adhere.]

Pears from Monte Video.—I have sent you to-day two Pears. They are from a barrel received from Monte Video. They are so good and in such excellent condition, that I thought it worth while to send them as a specimen. I am unable to give you the cost, as the barrel was a present.—J. L. [The Pears sent were, as J. L. says, very good—sweet, but gritty. They are large in size and look not unlike *Vicar* of Winkfield.]

Protecting Seed Beds from Birds (p.356).—The best and most inexpensive way of doing this is to place sticks about 1 ft. in length around the bed, and tie black thread from one to the other, thus forming a net. I have tried this plan for several seasons, and I find it to answer admirably.—T. F.

Double-spined Callas.—"N. S. S."—These are not uncommon; an illustration of one was given in *THE GARDEN* (Vol. X., p. 55).

Names of Plants.—*M*—1, undetermined; 2, *Pulmonaria officinalis*; 3, *Fumaria capensis*; 4, apparently *Genista sagittalis*; 5, *Porsythia viridissima*. *T. T. C.*—*Lydia*, but too withered to enable us to say what species. It requires to be grown in a moist, warm greenhouse. *Beta*.—The Cape leaf is that of the Silver Tree of the Cape of Good Hope (*Leucodendron argenteum*). *M*.—Your *Acer* is *A. rubrum*, North America. It may be propagated by cuttings or by seeds, the latter being preferable. *Vitis*.—1, *Dicksonia antarctica*; 2, *Doodia media*; 3, *Adiantum hispidulum*; 4, *Adiantum formosum*; 5, *Pellaea* (*Platyloma*) *rotundifolia*; 6, *Doodia candida*. *O. G. P.*—We cannot undertake to name plants from leaves only.

Questions.

Lily of the Valley.—Can any of your readers tell me whether it would be possible to grow Lilies of the Valley in Lucknow, and what is the best substitute for peat, which we cannot get here?—A LUCKNOW AMATEUR.

Fertilising Passion Flowers.—What is the *modus operandi* of fertilising *Passiflora quadrangularis* so as to obtain fruit? I have a fine young plant now showing abundant bloom in an intermediate stage. Should the shoots be stopped like those of a *Melon*? If so, should that be done before or after the expansion of the flower?—T. P.

GARDEN DESTROYERS.

OTIORHYNCHUS SULCATUS.

I HAVE selected this beetle for the subject of the present paper, as several of the correspondents of THE GARDEN appear to have recently had plants suffering from the attacks of the grubs of this insect, which belongs to the very numerous family of weevils, so many of which injure vegetation in various ways. Most insects are only injurious during one stage of their existence, but in the case of this insect both the beetles and grubs are very destructive to living plants. The grubs, however, are much more mischievous than their parents, and are only too frequently found destroying the roots of various plants cultivated in pots. When these plants begin to droop and wither without any apparent cause, the presence of these grubs may be suspected; and if they be the cause of the mischief, the roots of the plants will, on examination, be found to be considerably gnawed or eaten nearly through, generally just below the surface of the ground. Cyclamens, Primulas, Saxifrages, Sedums, and other succulent plants; Trollhuses, Adiantum pedatum, Strawberries, and Vines are the plants which suffer most from these grubs. The most certain way of getting rid of these pests is to replot the plants affected, taking care that none of the grubs are left among the roots or earth replaced in the pot. If replotting for any particular reason is undesirable, the roots may be examined by uncovering them as much as possible, for the grubs are generally tolerably near the surface.

Watering the roots with an infusion of Quassia or Tobacco-water has been recommended. Mr. Dunn, in his "Report on Injurious Insects for 1878," states that he has succeeded in stamping out this insect in his Vineries and Peach houses by dressing the roots of the plants during the dormant season with hot lime, soot, or salt. The weevil at times does considerable damage to Vines, Peaches, and Roses by feeding on their young shoots. They are very difficult to find on account of their dark colour, and of their habit of only feeding at night, remaining hidden in some shelter during the day. They may, however, be caught an hour or so after dark by spreading white cloths under the plants, into which the beetles will fall when the plants are shaken. These cloths should be spread while it is still daylight, as the beetles often drop from the plants on the sudden introduction of a light. The weevils make their appearance in June, and should be destroyed as soon as possible, so as not to give them an opportunity of laying their eggs. These are probably deposited below the surface of the earth, near or on the roots of the plants on which the grubs are to feed. At first the damage caused by the newly-hatched grubs is not noticed, but in the autumn, when they have increased considerably in size, they should be searched for carefully, if there be any reason for suspecting their presence, as it is during the winter and early spring months that they do most injury. In May they descend an inch or two into the earth, and there form small smooth chambers or cells, in which they undergo their change to the chrysalis state. In this state they remain for about a fortnight, at the end of which they leave their chrysalis cases and come forth perfect weevils. They are now about $\frac{3}{4}$ in. long, and entirely black in colour; the head is produced into a long snout, with a deep longitudinal groove or furrow down the middle, the tip of which is furnished with a pair of long antennae consisting of twelve joints; that nearest the base is very long and somewhat curved; the remaining joints are small, and form quite an elbow with the long joint, the four nearest the tip forming an oval knob. The thorax is broadest in the middle, where it is considerably wider than the head; it is covered with small, raised tubercles. The wing cases are much wider than the thorax and are oval in form, being broadest about the middle; they are much rounded transversely, and are sparingly sprinkled with small brownish spots composed of minute hairs. The legs are strong and of medium length; the thighs of the front pair are much thickened towards the knee joints, and are each armed with a strong tooth. The grubs are about $\frac{1}{2}$ in. long, and are generally in a somewhat curved position; they are stout, fleshy, much wrinkled, considerably thicker in the middle than at either end, and are entirely destitute of legs. The joints are thirteen in number, well defined, and of a dirty white colour, sparingly covered with stiff, brownish hairs. The head is reddish brown, and furnished with a strong pair of jaws.

Otiorhynchus sulcatus.

THE GOAT MOTH.

In the excellent descriptive paper on the Goat Moth (*Cossus ligniperda*)—p. 297—"S. G. S." says, "there are, unfortunately, but few means of destroying this insect." As the insidious and destructive effects of the larvæ are much more prevalent than is generally believed, the following statement may prove helpful to those who have to contend with the evil in question:—About the year 1840 the Royal Botanic Society obtained possession of the Inner Circle in the Regent's Park, up to which time this circular plot of ground was occupied and familiarly known as Jenkins' nursery ground. Among the earlier operations of transforming the then pasture fields into what is now the Regent's Park, anxious, of course, to create as speedily as possible a woodland aspect, the then officers of Her Majesty's Woods and Forests made plantations along the boundaries and elsewhere, and a line of Elm trees was about the same time planted round the outer boundary of what is now the garden of the Royal Botanic Society. During the year 1841, when the formation of the garden was in progress, it was discovered that a large number of the Elm trees forming the belt surrounding the garden were more or less affected by the larvæ of the Goat Moth. Many of the trees were sick, and some so unhealthy as to be beyond recovery. The following remedy was at once adopted:—Every tree was carefully examined; the presence of the insect was readily discovered; a strong round carpenter's chisel and hand mallet were the implements employed, and wherever the insect was found the hole or gallery in which the larvæ were deposited was followed by cutting into the bole of the tree. In some cases this operation had to be carried to the centre of the tree, and, not infrequently, at several parts of the stem of the same tree. By many the operation was thought to be so violent, that the trees thus treated could not possibly survive. When this severe operation was completed, and the bulk of the enemy was supposed to have been dispersed, a decoction of salt, lime, cow manure, and horse manure was made into the consistency of a thick paste, and every hole or wound on the stem of the tree was carefully filled up with this plaster; as a consequence of the unhealthy condition of the Elms, occasioned by the larvæ of the Goat Moth, the trees become the natural prey of the Scolytus. These burrowing insects had seized upon sickly trees in such countless myriads that they could not, like the *Cossus*, be sought for and removed individually; a simpler process was adopted, namely, using a brush and smearing the stems with a thick wash of the same ingredients as that employed to fill up the wounds in the stem. This smearing process was repeated several times at intervals, until it formed a $\frac{1}{4}$ in. to $\frac{1}{2}$ in. in thickness over the entire stem of the tree.

It will be sufficient to state that the results of these two operations were completely successful. The wounds in the stems of the trees healed with remarkable rapidity. Possibly the *Scolytus* was unable to escape through the thick plaster coating on the stems and was suffocated. I refrain, however, to dwell on the causes which produced these effects. My present purpose is rather to simply explain the operation which led to the results which I have described above, and to suggest to those who are the owners of trees the desirability of maintaining a watchful outlook against the stealthy inroads of the two enemies in question, for they are unhappily much less rare than is generally supposed. R. M.

—"S. G. S." (p. 297) and others of your readers may like to know that I have found the following method of destroying the Goat Moth (*Cossus ligniperda*) to be effectual in the case of matured timber: When the trunk of the tree is attacked, surround the orifice with clay, which will readily adhere to the rough bark, and form the clay into a cup, into which as much coal-tar should be poured as the cavity within will contain. The caterpillar will either try to escape at another hole, if there be another, and can easily be killed, or it will be smothered by the tar. If the tar be thick a little benzoline will make it liquid enough for the purpose, and neither will injure the tree. In the case of a young tree being attacked the bark may often be carefully cut away with a chisel and the caterpillar be found.—J. J. ROGERS.

OBITUARY.

DEATH OF MR. MUDD.—We regret to have to announce the death of Mr. William Mudd, the Curator of the Botanical Gardens, Cambridge, after a brief illness. Mr. Mudd was an associate of the Linnean Society, and, as a botanist, possessed a high reputation. The stipend attached to the office is about £100 a year; it is in the gift of the Botanical Garden Syndicate. The late curator, however, made a good addition to his income by instructing pupils studying for the Natural Sciences Tripos and the special examination in botany, and was a great favourite with the younger members of the university.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

WEeping TREES.

THE remarks of Mr. Burrows (p. 235) on "Weeping Trees" brings to mind a notice of a Weeping May Duke Cherry which appeared in THE GARDEN some weeks ago, and which is said to bear fruit equally well as the type or May Duke of our gardens. I hope our friends will not lose sight of this interesting object. I may say that I have been quite fascinated with the idea of a Weeping Cherry loaded with fruit. Imagine a row of such trees on a border in a garden, worked say 5 ft. high, loaded with fruit and drooping to the ground! How easily such a row of trees could be netted when the fruit was ripe! I am afraid the idea is too fanciful to be realised. *A propos* of weeping trees, I saw, many years ago, in a nursery the *Cydonia japonica* worked on stems 7 ft. or 8 ft. high. I thought them very beautiful looking objects, but at that time I was not curious enough to notice on what stock they were worked; nor can I imagine any stock suitable for them, except the Pear, the Medlar, or the Mountain Ash. Do any of the readers of THE GARDEN know anything of this matter?

When speaking of the artistic value of weeping trees in high-class landscape scenery, I should think that Mr. Burrows had in view such bold trees as weep naturally, and not freaks and sports, such as the Birch, the *Salix babylonica*, the Beech, the Deodar, and others. I am not certain that Mr. Burrows is quite correct in advocating the isolation of such trees wholly on lawns, and I would point out that the beauty of such trees is very much enhanced by their proximity to others of an ordinary character. Who has not seen in some ravine or glen the white-stemmed Weeping Birch, waving its tresses of pendent spray among its companions? Such a tree in association is far more beautiful than in isolation. In a plantation of trees on the north side of a garden near here is a towering Weeping Birch which, as seen from all parts of the garden, seems to be the spirit of the whole place, and in reality neutralises the beauty of its surroundings. Yet I must maintain that this tree would look anything but well by itself; standing against the sky-line, it would, from its delicacy, be almost lost.

I quite agree with Mr. Burrows that the lawn is the proper place for such weeping trees as those with which we are familiar. They are, however, truly formal and avowedly artificial, and should be sparingly introduced, and in some instances not at all, and nothing but a vitiated taste would sanction their use in well-kept places. Their only position seems to be in association with architectural terraces, statuary, fountains, &c., for a tree with its branches all growing downwards is just about as natural as jets of water thrown upwards. The main fault with most of these trees is that the branches all drop from a given point, and only one; whereas, in such trees as the old Weeping Willow the falling tresses of spray are broken and diversified, like water in a mountain cascade. Allow me to point out a method by which this excessive formality may be modified. Take the Weeping Ash as an illustration; when planting this tree, fasten a stout iron rod to the stem, and let it extend upwards through the centre about a yard or so; to this upright rod train a branch vertically; it will soon throw out branches tier above tier, and the process should be continued till the desired height is attained, which may be 30 ft. This process will give the tree a pure fountain-like appearance, wholly distinct from the forms which such trees generally assume.

THOS. WILLIAMS.

Ormskirk.

A HISTORICAL YEW HEDGE.

HISTORICAL trees have long since found their poets and biographers. Who can forget Queen Cunigund's Lime tree in the courtyard of the Castle at Nuremberg, said to have been planted by that sainted, if somewhat mythical, lady at the beginning of the eleventh century? or King John's Oak, that patriarch of the forest, who still holds his own in "Merrie Shrewsbore," or his

Famous brother Oak
Wherein the younger Charles abode
Till all the paths were dim,
And far below the Roundhead rode
And hummed a surly hymn.

I do not know if anyone has treated of historical hedges; such a one is that which encloses the Rectory Garden at Bishopsbourne. On blustering and inclement Easter Monday the writer of this

note drove there from Canterbury, a distance of four miles on the Dover road; the last mile takes you through Bourne Park, a picturesque spot beautifully planted. Bishopsbourne itself is a small village, quiet and unpretending, but interesting to the student as the place where Richard Hooker spent the last years of his life, and where he composed that great work which has rendered his name immortal. He was a remarkable man in a remarkable age, a veteran in that mighty company of writers who adorned "the spacious times of great Elizabeth."

The object of my visit was to see his monument in the parish church, and the old rooms in the rectory which he had inhabited. The house has been modernised and enlarged, but two rooms in it remain as they were in Hooker's days, and the garden is almost entirely surrounded by a Yew hedge which he planted. Part of this is 36 yards in length; it is met at right angles by a shorter hedge, 33 yards long; both are from 12 ft. to 14 ft. high. There is a curious summer-house at the end cut out of the hedge, where it is much broader, and at least 20 ft. high. Two men are employed for a fortnight in September in cutting these hedges; they stand on the top to complete that part, and there is a firm path which supports their weight, as they only sink in a few inches. The hedges are about 9 ft. thick; behind them is a Grassy path, where tradition says Hooker used to walk, meditating his great work. No doubt he, with his friend Dr. Saravia, one of the prebends of Canterbury, passed many happy hours, as they

Discussed the books to love or hate,
Or touched the changes of the state,
Or threaded some Socratic dream.

Hooker, like many of the sons of genius, was (as we know) particularly unfortunate in his marriage. Unblessed by affection, he took refuge in friendship; and it is to one of those faithful and tried companions of his solitude that we are indebted for the interesting though uneventful record of his life.

All this came unto my mind as I walked in the rectory gardens with the rector's wife, who was a kind and patient cicerone. A Grassy bank sloped down from the hedge to the house, from which it was divided by a gravel walk. Several beds were cut out in this bank, which were filled by many of those flowers

Which their gay wardrobe wear
When first the Blackthorn blows—

Scillas, white and pink *Hyacinths*, and *Daffodils*. In this sheltered spot they bloomed freely while the east wind was blowing hard and the snow lay thick on the hills. Few were the traces of the spring outside; here and there, amid brown Grass and dead leaves, *Primroses* faintly shone in the banks and copses, but here in this favoured garden no wintry blast could reach April's first-born flowers.

I often wonder that gardens in exposed situations are not oftener enclosed and defended by Yew hedges. Perhaps their slow growth (the one I have described was planted the latter end of the 16th century), and the trouble and expense of having them cut, may account for this neglect. They are both useful and ornamental, and they give an air of retirement and privacy which is delightful. Bacon recommends "a stately hedge which is to enclose the garden;" but there is too much carpenter's work in it for my taste; I prefer something more natural, and would rather read about it in his charming essay than have it before my eyes in my humble garden.

Chaucer might have had my hedge in his mind, when he writes in "The Flower and Leaf" of a

Hedge as thick as a castle wall,
That who list lit without to stond or go,
Though he should all day prien to and fro,
He should not see if there were any wight
Within or no.

But this hedge was set with "Sicamour and Eglatere."

A fine Yew hedge not far from here, in an old-fashioned pleasure-ground has always struck me very much. It divides a beautiful flower garden from a part devoted to more useful plants. It is 35 ft., or 40 ft. long, and 12 ft., or 14 ft. thick, and was probably planted about 200 years ago, being as old as the house, which is of that time. It was built by an ancestor of the accomplished author of the "Descent of Man," and still remains in the Darwin family.

N.

Toxicophlæa speciosa (Thunbergi).—Many complain that it is difficult to flower this fine Cape shrub, and under ordinary treatment this is true, but at the Alexandra Palace meeting lately have been seen a fine plant of it flowering most profusely. This plant had been grown well during the summer in a brisk heat well exposed, and during the winter it was allowed to get dry at the roots, though in a moderately damp atmosphere; this, it is believed, has been the cause of success. It is a plant which will stand a considerable amount of rough usage, and when in flower it is well worth a place in collections in which good flowers are valued. The

plant at the Alexandra Palace is 6 ft. high, and is clothed with foliage to the top, and bears bunches of white leaves in the axils of all the leaves.—J. CROUCHER.

Pinus insignis.—I quite agree with Mr. Rogers, that this Pine is beyond comparison the most beautiful of its family, but it is too tender for cold, exposed situations. Two-thirds of those planted by me on the Surrey Hills have been killed by the weather; those left have not suffered for the last two years, and may, perhaps, get used to our climate. Through England and Scotland generally, *Pinus austriaca*, as a screen and as shelter, is far safer than *insignis*; still, the latter should be planted all over large areas, for the chance of its thriving.—A SUBSCRIBER.

Butcher's Broom.—"G." (p. 363) is right respecting the common Butcher's Broom (*Ruscus aculeatus*) growing wild in Glamorganshire. In the woods at Penrice Castle, about 12 miles southwest from Swansea, it grows in carlodes, but for my part I consider it neither very ornamental nor useful.—CAMBRIAN.

THE FLOWER GARDEN.

WALLFLOWERS IN CITIES AND VILLA GARDENS.

THE Wallflower is one of the most popular, as well as one of the gayest, of spring flowers. Although it thrives and blooms profusely in almost any situation, yet it never appears so appropriately placed as when growing in the immediate vicinity of dwelling-houses, which it brightens up early in the year with its fragrant flowers, the perfume of which is of the most agreeable and refreshing description. The Wallflower, like the Violet and the Primrose, is a universal favourite, and we scarcely seem to realise that spring has arrived until its cheerful blooms make their appearance. More especially amongst the poor is it cherished, not only in country districts, where it may generally be found flanking the cottage doors, but its low price places it within the reach of the working classes within our crowded cities, who can oftentimes indulge in the luxury of a bunch of Wallflowers when flowers in general are too dear for them to purchase. Any one who has visited Covent Garden Market during the early hours of a May morning will have remarked the fine bunches of Wallflowers which are bought up in large quantities by the hucksters and carried away by them to be sold at a cheap rate in poorer districts of the metropolis. These are, of course, grown in the vicinity of London, and they are so fresh and bright, and exhale such a delicious odour, that one cannot help wishing that every poor inhabitant of the great city might be enabled to brighten up their homes with them.

In most large gardens there are spaces which remain vacant, spots far removed from the dwelling which it is not considered necessary to occupy with bedding plants, or of which the soil is of a very poor description. All such unoccupied pieces of ground might be filled with Wallflowers; hard, strong, sandy soil in which most plants refuse to thrive will yield a rich harvest of bloom, and even odd corners may be made to furnish their quota of this easily-accommodated spring flower. To such an extent might Wallflowers indeed in many places be grown, as to render it no difficult task to cut a cartload of bloom in a week. Although we feel the need of flowers the whole year through, we yet seem now particularly to crave for their bright presence, when from a gloomy winter we emerge into the bright sunny days of spring. It is just at this time that bloom is scarce. In the summer there is, owing to the profusion of flowering plants that we now possess, no difficulty in supplying our flower missions. In the spring time growers are naturally reluctant to gather their first blooms, but if all the odd sunny corners and waste spots of ground were, as I have said, planted with Wallflowers, enough would be furnished to gladden the heart of many a poor sufferer, and that without in any way detracting from the appearance or in any way robbing the dressed grounds.

The Wallflower is of a hardy character, and if once planted and left undisturbed, allowing some seed to ripen, it will propagate itself without further trouble. If a large plant once seeds the immediate vicinity will be stocked for years. Cottagers scarcely ever take the trouble to raise seedlings enough to come up yearly to supply the places of those that wear out. It is true that the Wallflower, like all other plants, repays with interest generous culture, and that flowers obtained without any special care being expended upon their growth could not be expected to rival those which are brought into the market from good ground. But the poor accept with delight anything which presents the slightest appearance of bloom. Those who revel in floral beauty the whole year through can scarcely realise the intense pleasure which the commonest flower affords to a pent-up denizen of our great smoke-begrimed city; and could they witness, as

I have done, the care lavished upon such common plants as the Mistletoe, which have been dug up in the fields and sold for one-halfpenny each, they could not but be well assured that the gift of a bunch of fragrant flowers would be received with delight.

Apart, however, from this philanthropic view of Wallflower culture, there is no question that this plant might be made to play a more important part than it generally does in spring decoration. Cottagers are very partial to the Wallflower; they generally plant them close to their walls, near the entrance and under the windows of their dwellings. In such situations it luxuriates, for it never seems more at home than when the roots can in some way feel the bricks and mortar. It is in such places that the double varieties do best and live longest. They not only grow more freely, but they often escape the ruinous effects of a sharp winter when those in the open get killed. It is worthy of note, and probably explains in a great measure the comparative absence of these double varieties from villa gardens, that they are scarcely ever to be found placed in these naturally congenial positions. Being consigned to the borders, they seldom survive a very sharp winter, and it frequently happens that not a plant in the entire district escapes; the variety is then often lost for a number of years. These double kinds are grateful for a little protection, and they should receive it in severe winters. There should be no difficulty in finding suitable situations for them. Why not plant, as cottagers do, both the double and single kinds in conspicuous positions close to the walls, in the front of the sunny side of the dwelling? When in bloom, they would fill the air and the house with perfume. The side and end walls of greenhouses might also be thus occupied; such plants do very well even in the framework, if once established. There is no need to prepare a border for them; a little good soil, just to give the cutting or seedling plant a start, is all that is needed; in this they will speedily establish themselves, needing no further care, and oftentimes showing more satisfaction than if placed among other denizens of the garden.

In conclusion, let me recommend that unoccupied pieces of wall, semi-cultivated and stony, barren pieces of ground be occupied with Wallflowers; the expense and labour will be of the smallest description, and would be more than repaid by the large amount of bloom thus rendered available for cutting, and by the general cheerful appearance of the garden at an early period of the year.

Byfleet.

JOHN CORNHILL.

HYACINTH CULTIVATION IN HOLLAND.

YEARS ago, when Hyacinths were still so high in price that they were only to be had by the rich, there were just a few gardens around Haarlem where these bulbs were grown, and the stock was small at that time. Since the railways and steamers go direct to nearly every part of the world, the nurserymen of Haarlem are producing more stock, and have arranged new nurseries for this valuable plant, so that at present in spring the country around Haarlem for many miles to the north and south is in reality a flower garden. The nurseries generally lie along the dunes (low sand hills), and the soil is almost pure sand, varying in colour from white and yellow to brown and grayish black, which great difference enables the nurserymen to give the Hyacinth every year a different and at the same time a quite fresh soil. During the winter, those places where Hyacinths are to be planted next autumn are trenched 3 ft. and sometimes even 5 ft. deep, in order to bring the soil in which the Hyacinths have grown one year down deep in the ground, and also to get a fresh soil on the surface. In March and April the soil is enriched with cow manure, after which green crops or Potatoes are planted, and it is dug again in autumn about 15 in. deep before it is ready for the Hyacinth.

In the end of August growers begin planting the bulbs, in oblong rectangular beds, about 3½ ft. in width—the depth varying according to the different ages of the Hyacinths, and to the nature of the ground, also to the height the soil lies above the level of the water. By the end of November all the Hyacinths are covered with reed mulching about 1 in. thick, which is taken away in February or March when the frost is over; and if the leaves which are now just coming out of the ground look yellow, they are lightly covered again till they are quite green, when the reed is taken away.

About the 15th of April generally the Hyacinths are in bloom. It is at that time the environs of Haarlem present that splendid sight for which they are renowned. Flowers everywhere, and when there is no wind the air is filled with their rich perfume. When they begin to wither, they are all carefully cut off in order to prevent the bulb from becoming too much exhausted, and are strewn over the land where Potatoes are planted to prevent the sand from being blown away by the winds. This bed of flowers is also of great benefit to the land, as there is some manure in it. Directly after the flowers are cut off, the bulbs begin to grow; the leaves erect themselves and get taller. The weather during May and June decides whether there

will be a good crop or not. For the last two years the Hyacinths have been badly injured during these months by honey dews and storms, so that it will require at least one good season to bring the stock up right again.

About the last of June the growers begin to take the bulbs out of the ground, and this is the time to multiply them, which is done in two different ways: Coming fresh out of the ground, the bottoms of the oldest and largest bulbs are cut into six or eight equal parts, about the thickness of the height of the bulb; this mode of cultivating is called "crossing." Next year the old bulb is gone (decayed), and on the separated parts of the bottom of the bulb, between the shells, about twenty young ones are grown. The small bulbs got in this way require four years before they are large enough to be sold or to be crossed again.

The other way of cultivating is called, in Dutch, "hollowing," in English, "scooping out," which means, to make a hole. Probably every one knows that a Hyacinth consists of several shells arranged like an Onion, coming together at the bottom, and in the centre of which is the flower. By the end of July, when the weather is fine and dry, this bottom is carefully cut out, so that nothing is left but the shells. The bulbs being severally wounded, are put in the draft or sunshine to dry. After two or three weeks, when the wound is quite dry and hard, a great many small white nobs may be seen near the dry part of the shells; and being planted in the autumn of next year, all these knobs will become very small young Hyacinths, that do not bloom for two or three years, and take six, and sometimes even eight, years to grow to the ordinary size. By this way of cultivating, one bulb produces from 60 to 150 young ones.

Next year the young ones are separated, when crossed, or picked off the old dry shells in the other way of cultivating; planted free in autumn, and lifted again in June, and so on for several years, which depends on the sort growing fast or slow, until the bulb is old enough for the market, or to be used for cultivation. By applying these methods of cultivation every year, different stocks are obtained, which are treated according to their age. The Hyacinths, after being all lifted, are buried again in the earth in order to let the roots die off, and to enable the bulb to close itself (ripen). After a fortnight they are taken out again, and dried for an hour or so in the sunshine; then sifted to get the sand away, and brought into the bulb house, where they are laid out on wooden tables in the draught—for the windows of a bulb house are only shut when the weather is damp.

By the end of July or beginning of August, the bulbs are sent out; so everybody may comprehend that it is necessary to send in their orders for flower roots by the beginning of July. New sorts of Hyacinths are got from seed, which takes a very long time, as the grain of seed wants eight, sometimes even ten, years to grow, until the bulb is large enough to produce a good flower; and then the grower possesses only a single bulb. So it may be imagined what a long time it requires, as well as the great cost it incurs, to secure a stock of such novelties.—Case's "Botanical Index."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Myosotis dissitiflora.—We have a long border now very bright and showy with this Forget-me-not. In other places there are irregular patches, some clustering where self-sown under the shade of pyramidal fruit trees, others in the full sunshine; but I do not believe we have lost a plant from the effects of the long and severe winter which we have had. I like seedlings better than plants raised from cuttings; but I have not made use of cuttings lately, thinking that the plants so raised lacked stamina in comparison with seedlings. For the last two years I have not sown seeds either, as young plants come up in thousands about the borders from self-sown seeds. Seeds of this Forget-me-not produced early ripen and scatter themselves before the later flowers are over, and the young plants from early-sown seeds are in excellent condition for transplanting in October. The seeds of this Forget-me-not are generally sown too late; they should be put in much earlier than those of the Californian annuals; the middle of June in the north of London is none too early. I think it is best to sow in a partially shaded situation, such as on the shady side of a row of espalier or bush fruit trees, although I confess that when seeds are self-sown they seem indifferent as regards aspect.—E. HOBDAV.

I have tested in various ways the relative merits of this Forget-me-not raised from seeds and from cuttings, and I cannot perceive the least difference between plants of it raised in both ways. I have raised many hundreds from cuttings, and in examining beds of them at present I find that not one plant in fifty has been killed by the late severe winter. All of them are now in full bloom, but

many of the flowers have not that beautiful azure-blue which is natural to them, but a lilac shade instead, doubtless the result of frosty nights and cold winds. I have this season more plants raised from cuttings than from seeds. I put the cuttings in on July 22 in 5-in. pots, and placed them in a cold frame behind a north wall, so that they might be kept from the sun without using other shading material, and I transplanted them on August 26 6 in. apart on an open border of light soil in the kitchen garden. They were planted out into the flower beds on the 31st of October. The seed I sow about the third week in June, and transplant about the time when the cuttings are ready. If the weather be hot and dry it is absolutely necessary to shade and water the seed, or it will be some weeks before it begins to vegetate.—D. WALKER, *Dunorian, Tunbridge Wells*.

Flowers in Churchyards.—All of us are familiar with the display made with flowers in many of the cemeteries that adjoin large towns; but in some instances this partakes too much of the character of the bedding-out system, and rather disturbs than assists to create that feeling of repose which should prevail in churchyards. In this respect many old-fashioned churchyards in rural districts are models that might well be copied. I lately saw one situated on undulating ground, which, although but lately restored, had its ancient character carefully preserved. The old crumbling walls were clothed with Wallflower and hardy Ferns, and the massive iron railings of tombs were draped with climbing Roses. The venerable Yews and Walnut trees that had for centuries grown unpruned and undisturbed formed striking monuments of the past, and springing from the turf at their base were large masses of Daffodils, Jonquils, and Tulips, but perhaps the most effective and appropriate of all was a carpet of Forget-me-nots that had self-sown themselves in all directions, and in the partial shelter of this secluded spot had withstood the inclement season far better than those on bare flower beds. I may add that Arabis, Aubrietias, Saxifrages and similar plants also do well and take care of themselves.—J. G.

Primroses.—Much has lately been written about Primroses, and, as spring flowers for embellishing uncultivated places, too much cannot be said in their favour. Here we have quite two dozen different shades of colour, and most effective they look when growing in patches together; but nowhere do they look so well as when clustering around old tree stumps or under the spreading branches of rustic-looking trees. In this way many of them may be seen in the pleasure-grounds here at present, and every one who sees them is perfectly charmed with them. Where they do not exist in such places it would be time and labour well spent to endeavour to establish them.—CAMBERIAN.

Early Violas.—With us none of the yellow Violas named by "A. D." (p. 347) bloom so early and well as Dickson's Golden Bedder, which, in my opinion, is the best for bedding purposes, either in spring or summer. Next to this comes Dickson's Sovereign. Of blue or purple shades, The Tory far outstrips all others in the earliness and profuseness of its blooms, as well as in the richness of its colour. Cliveden Purple is very inferior to Holyrood, which, as a true purple for spring and summer bedding, would be hard to beat. Neither Dean's nor Dickson's lilacina are of much merit.—CAMBERIAN.

Dielytra spectabilis.—The severe frost of April 12th, when the ground was frozen quite hard, laid our beds of *Dielytra* prostrate and apparently dead, but with the return of milder days they gradually assumed an erect position, and are now bursting into fall beauty. I have in former years seen this beautiful plant quite killed to the ground with less frost than it has resisted this year; its hardness on this occasion being doubtless owing to the more hardened character of its naturally soft growth, arising from the exceptionally severe character of the season in which its growth was made.—J. GROOM.

Crown Imperials.—Mr. Hobday (p. 348) seems to think his Crown Imperials worthy of remark, because their stems are "3 ft. high," and "bear six flowers in the whorl." If he is in my neighbourhood and will favour me with a call, I shall be glad to show him specimens of the same plants, both red and yellow—the former 3½ ft. high with eight flowers in the whorl, and several of the latter from 3½ ft. to 4 ft. high with flowers varying in number from eight to thirteen in a whorl.—H. P. DUNSTON.

Gentiana acaulis.—One of the most striking objects in gardens at present is this lovely deep blue Gentian, which is simply unique as regards colour, and, being so very dwarf, it makes a good edging for small beds.—J. G.

Cinerarias.—Blossoms of these belonging to a choice strain have been sent to us by Messrs. F. and A. Smith, of Dulwich. They are bright in colour, and, as regards form and substance, are all that could be desired.

EFFECTS OF FROST IN THE SOUTH-EAST OF IRELAND.

Our chief losses amongst out-door plants from last winter's frost have been half-hardy plants of kinds which are usually quite hardy here within three miles of the sea. The soil is light, the situation sheltered, and the subsoil gravel. Myrtles have been greatly injured. A plant of sweet-scented Verbena, about 12 ft. high, in a well sheltered corner, shows as yet no sign of life; it had lived out uninjured for many years; a large plant of the common Passion-flower, which has lived out against the house for very many years, is almost killed; it is too soon as yet to know whether either of these will recover. A plant of *Coronilla glauca*, also in a sheltered corner, which had lived out-of-doors for some years, and sometimes blossomed almost the whole winter through, is killed, as is also a plant of *Maurandia Barclayana*, which had lived out-of-doors for two or three years. Of *Tropeolum tuberosum*, which grew luxuriantly amongst *Rhododendrons*, making banks of bloom in sunny positions through the autumn, almost every bulb is apparently killed. Almost every *Dahlia* has also been killed, being, as usual, left in the ground and covered with coal ashes during winter. *Lobelia fulgens*, that most brilliant autumn-bedding plant, usually quite hardy here, is much injured; indeed, we fear that most of it is killed. Beds of double *Daisies* are late in flowering, as many of them were completely lifted out of the ground by the frost. *Anemones* from Pau are also late, but are flowering well, and in good time for contrasting with beds of *Poet's Narcissus*, double *Jonquils*, and *Forget-me-nots*. The latter (*Myosotis dissitiflora*) required to be replanted here and there, as some of the plants were killed. The *Pampas Grass* is also injured.

Amongst plants on rockwork there have been perhaps as few losses as during our ordinary mild, damp winters. To Canadian, North Asiatic, North European, Swiss, and Pyrenean plants, the dry cold of last winter was probably less trying than our usual winters, but plants from warmer countries have stood it well. Of Cape bulbs, such as *Ixia*, *Babianad*, &c., some have already come up, and probably others will do so later. *Crinum capense*, *Iris Pavia*, *Lachenalia quadricolor*, *Schizostylis coccinea*, *Oxalis versicolor* and *Bowiei* are alive; the latter comes up every year, but never blossoms. The German Ivy, also from the Cape, appears to be dead; *Agapanthus umbellatus* and the *Belladonna Lily*, though not on rockwork, have survived.

Of New Zealand and Australian rock plants, *Acacia microphylla*, *Fuchsia procumbens*, *Mazus Pumilio*, *Nertera depressa*, *Polystichum vestitum*, and the New Holland Daisy, are uninjured; but the New Holland Violet, always very delicate here in winter, died; and the New Zealand *Veronica pinguifolia* has been almost killed; a branch or two which had been layered may perhaps survive.

The following South American plants are alive, viz., *Triteleia uniflora*, *Oxalis floribunda*, both white and rose; *Tropeolum speciosum* and *polyphyllum*, *Geum coccineum*, *Calandrinia umbellata* (of this one plant survives), and *Mimulus cupreus* from Chili; but *Malva campanulata*, also from Chili, appears to be dead.

Of Mexican plants, *Commelina tuberosa* is dead, and but one small piece of *Escheveria secunda* (or *E. secunda glauca*) survived. *Oxalis lasiandra* has not yet come up, but it does not usually appear till late in the season.

Disandra prostrata, from the Canary Islands and Madeira, and *Myosotis azorica*, from the Azores, are alive. *Convolvulus mauritanicus*, from North Africa, died, though usually hardy here. *Convolvulus Caeorum*, from the Levant, is so much injured that its recovery is doubtful, though *Muscari moschatum* and *Tulipa cornuta*, also from the Levant, are uninjured. *Aethionema cordifolium*, from Mount Lebanon, and one or two other Syrian plants; also *Fritillaria persica*, *Tulipa persica*, and *Crucianella stylosa*, from Persia; and *Bambusa Fortunei*, *Dielstra spectabilis*, and *Saxifraga sarmentosa*, from China, are uninjured; but *Plumbago Larpentia*, also from China, planted last autumn, has not yet come up. We have got this flower three different times, planted it with care in autumn, and it has never appeared. Is it thoroughly hardy? [Yes.—Ed.]

Japanese *Primroses*, *Anemones*, *Epimedium macranthum*, *Funkias*, *Sedum spectabile*, *Spirea palmata*, *Polygonatum japonicum*, and some other Japanese plants are uninjured. This *Polygonatum* we have had for some years, but it has never borne berries, nor do I think it has even bloomed.

Of Himalayan plants, *Androsace lanuginosa* is uninjured; *Polygonum vacciniifolium* is injured, but not killed; *Rhododendron ciliatum* has produced few blossoms, as most of its flower-buds were killed; otherwise, this *Rhododendron* is uninjured. Of many kinds of Himalayan, Japanese, and European *Primulas* the only kinds which we have lost is *scotica*; the hot sun of last summer is, however, as likely as last winter's frost to have killed most of these latter.

Of many kinds of *Campanulas* all are uninjured by the frost, including the Italian *C. Barbellieri* (almost impossible to preserve from slugs), *garganica*, *fragilis*, *hirsuta*, and *isophylla*. Most of our rock plants belonging to Central and Southern Europe have survived, including *Sedum neglectum* from Naples, *Helianthemum formosum* from Portugal, *Veronica lactea* from the Balearic Isles, and others. *Sedum carneum variegatum*, though considered not quite hardy, has survived, as has also *Selaginella denticulata*, though one or two pieces of the latter were killed. *Sarracenia flava*, though a very small plant, lived through the winter. Some of these plants were protected by finger glasses or pieces of glass during the winter, otherwise they were unprotected? One plant of *Edelweiss* was killed; another close beside it remained uninjured. Leaves of the common Ivy are much injured. *Roses* and *Carnations* have not suffered much, if at all.

The only vegetables which were killed here were some small seedlings of *Veitch's Autumn Giant Cauliflower* sown in autumn as an experiment. They survived the December frost, being partly covered with frozen snow. This snow was such a protection that I believe few, if any, of the plants which we lost last winter would have suffered were it not for the January and February frosts alternating with thaws, although the December frost was much the longest and probably the hardest.

Gorey, Ireland.

CHILDREN'S GARDENS.

I CAN fully endorse all Mr. Hobday has said (p. 329) regarding the great benefits which young people derive from a pastime so instructing and ennobling as the culture of flowers. When begun in early years the love of it continues through life, enlarges the powers of observation, and gives more real enjoyment than can be derived from any other source. Thousands go through the world without even knowing the names of even the commonest of plants, and pass them by unobserved; but if their early thoughts had been directed towards them, they would see beauty in all of them, for, as Shakespeare says: "There is not a plant, a leaf, but contains a folio volume; you may read, and read, and still find something new, something to instruct, even in the noisome weed." This is true; and those unacquainted with such subjects lose half the pleasures of life. If we only take a rooted blade of Grass and examine it, we may see how wonderfully well adapted it is for the purpose for which it is intended, and the same holds good in everything else. The structure of plants is a study in itself, and as seedling is the first aim and end of all plants, how marvelously this is provided for in the different kinds. Take the *Fuchsia*, for instance; its flowers are pendulous, and in them and others of similar character the stigma is long, and hangs beneath the anthers in order that the pollen, when ripe, may drop on it. In order, too, to insure its being caught in its descent, a viscid matter is exuded, to which the pollen-grains stick till their allotted functions are performed. In erect flowers this is reversed, and, as if to make sure that there shall be no failing, the blooms of *Primulas* cannot fall without being dragged or slipped over the pistil, on the end of which is the stigma, and in their passage over they must of necessity leave some of their pollen behind, the anthers being seated on and attached to the tube. These are only illustrations of the adaptations of the different organisms, and show how much there is to interest even ordinary observers, and what is missed by those who never look at anything, except in a casual manner. That a love of plants is innate with most of us may be seen by any one who visits our cities and towns, where, even in the most poverty-stricken parts, window-sills are crowded with flower-pots, broken jugs, and all kinds of nondescript earthenware filled with soil, in the hope of coaxing a little verdure out of it. As the so-called mould in these vessels is generally the scrapings and gatherings of streets, these would be gardeners labour under great difficulties, independent of the soot, smoke, and dust with which they have to contend; but it is something to them to mark how plants grow and seeds germinate, roots penetrate the earth and buds and leaves unfold, each movement being watched with the most lively interest. If in towns so much pleasure is to be derived from a bit of green, how greatly privileged are those in the country who can have their plot of land attached to their residences. I would urge on all so circumstanced to set apart a portion for the youngsters, as there it will be found they will spend their happiest hours, acquire knowledge, and get imbued with a feeling and love for flowers that will never leave them. Who can estimate the amount of good derived from such a start, or gauge in any degree the softening influence which it brings to bear on our rugged nature? That it has a great effect in this direction is, I believe, a fact that no one will venture to controvert.

S. D.

THE INDOOR GARDEN.

THE TRUMPET TREE.

(CECROPIA PELTATA.)

THIS remarkably handsome member of the Bread-fruit family when fully grown reaches a height of quite 50 ft., and its leafy branches stand out nearly at right angles with the stem, thus forming a more or less rounded and spreading head. The most striking peculiarity about this tree is perhaps its hollow trunk, which has transverse partitions inside analogous to those in a Bamboo, only in this case they correspond in number with the scars which represent the positions where the long-stalked leaves once grew. The rough digitate leaves themselves are covered on the under surface with white down, and are commonly eaten by the sloth; the young buds form when cooked a useful vegetable, and the bark when young is tough and may be used for cordage, while the old cortex may be employed in certain cases as an astringent. The wood is exceedingly

Cecropia Peltata.

light when dry, and forms an excellent substitute for cork in the making of floats for fishing nets. The toughness of its bark fibre, and the production of caoutchouc by its milky juice, are properties general throughout the whole Order, and well illustrated in *Castilloa elastica*, which produces excellent rubber, and also by maceration and beating a serviceable bark-cloth of fine texture. Perhaps the most singular use to which the wood of this tree is put is the formation of a peculiar instrument of percussion, used by the Indians of the Rio Maupes, a tributary of the Rio Negro. A section of the trunk 5 in. or 6 in. in diameter and about 4 ft. long is selected; the partitions are removed and the inside is rendered smooth by fire. The lower end of the cylinder is then filled with caoutchouc and leaves beaten down into a solid mass, and a handle is formed by cutting two holes near the upper end. During the holiday fêtes and dances these drums are used by the performers, who, holding them by the handles, beat the lower end on the ground as an accompaniment to the movements of the feet. This instrument is called "Amboobas" or "Em-accompanying illustration represents a young specimen before the banba," a name by which the tree itself is also popularly known. The branching stage as it pushes its way up into light and air through

Moss or Usnea-draped branches, on which Bromeliads and Ferns have also made themselves at home. The engraving is also suggestive in another way as illustrating a phase of epiphytal plant-life not generally recognised by cultivators at home who will persist in growing Bromeliads in pots and, as a rule, treating them to a dry-as-dust system of culture, notwithstanding that in the South American forests they are in many cases as purely epiphytal as their neighbours the Orchids and the Ferns, and as thoroughly enjoy the heat and moisture which they naturally obtain during the rainy season. Grown in small baskets of fibrous loam, peat or leaf-mould, and living Sphagnum Moss, in a genial temperature, suspended near the light, and deluged with water when growing, many Bromeliads would rival even Orchids themselves in diversity of leafage and flower beauty. B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Japan Primroses.—During the past week the collection of Japan Primulas of the amœna family growing in the seed grounds at Bedford has been in fine condition. Exceeding, as it does, all other Primroses in its power to produce variety, the amœna section possesses an undoubted claim upon popular favour, and although the numbers of seedlings that have been raised have so far been limited, yet some two dozen or so of distinct form have been the result. These forms embrace two distinct divisions in the formation of the flowers, that is, some are smooth and round in petal, whilst others are charmingly fringed and singularly graceful; all, however, are very beautiful. The rich, red-coloured, original amœna has been eclipsed in depth of hue by the elegant kind called *lacinata*; *lilacina* has increased the depth of its bluish tints in *purpurea* and *Ophelia*; *grandiflora* is quite outdone in size and colour by *maxima*; and *alba* has produced not only finer smooth-edged forms, but some pure white and beautifully laciniated. The variety named *Snowflake*, one of Mr. Allen's seedlings, is a beautiful descendant from this old form. The permanent clumps, growing in 8-in. pots, and throwing up large numbers of flower-stems, are also producing fine blooms, thus showing that to produce the highest kind of beauty in these flowers the plants must not only be well established, but the pots should be full of roots. In comparison with the forms of amœna the better-known *P. japonica* looks stiff and formal, whilst from seed it simply reproduces itself. The newer kinds may be propagated most freely by roots, although seedling sparingly, but the tendency to produce variety in what little is obtained somewhat compensates for that scarcity. In a few years good clumps of these very hardy and charming Primroses will be found in every greenhouse and conservatory.—A. D.

Tropeolium tricolorum as a Window Plant.—There are few more suitable subjects for window culture than this pretty little climbing plant; it succeeds admirably in a cool room from whence frost is excluded. An east aspect suits it best, where it may catch the morning sun, but where it is screened from its noontday glare, for, although this species of *Tropeolium* loves the light, it dislikes hot sunshine. It delights in a cool, equable, and rather moist atmosphere, and flourishes better in a temperature of 55° than when subjected to a stronger heat. It may be trained in various ways, either upon a small balloon-shaped or flat trellis, or, what is still better, and where it assumes its true character, it may be trained up strings on each side of the window, and allowed to festoon and droop down naturally from the upper part of it. The bulbs should be potted in September and plunged in a cold frame, where they need but little water until they have made considerable growth. In November they may be placed where they are to flower, and should be carefully watered, giving only just enough to moisten the soil through. In April, when in full growth, they will require to be more freely supplied, and a little weak lime or soot water will very much increase the vigour of the plant and the size of the blooms.—J. CORNHILL.

Fructing Passiflora quadrangularis.—"T. P." (p. 365) should allow his plant of this to grow as fast as it will at the extremities of the shoots, and flowers will be produced along their whole length; if these be fertilised with a camel's-hair pencil about noon every day, as they expand and the pollen becomes dry, he will secure an abundant crop. Stopping the shoots does not answer, but where too crowded they should be thinned out, cutting those not wanted away entirely. The plant fruits best when confined to a large pot or tub. Some have asserted that *P. quadrangularis* will not set its fruit unless fertilised with pollen of another variety; but that is a mistake. We grew the plant systematically at one time in a house devoted to it, and fruited it abundantly every season. The year after the plant was struck from a cutting it produced fifty fruit, each being $\frac{1}{2}$ lb. in weight.—J. S. W.

Saxifraga sarmentosa mixed with Ferns.—This Saxifrage always makes an elegant basket plant, but its beauty is much enhanced when mixed with Ferns of like hardiness. The other day we noticed several suspended pans containing a hardy Fern in the centre and the Saxifrage gracefully hanging over the sides, multiplying itself abundantly. The Ferns used were *Cyrtomium falcatum*, *Aspidium angulare*, *Pteris cretica*, &c. These make charming baskets for suspending in windows, especially in towns, as such plants seem quite indifferent to a smoky atmosphere.—W. G.

THE FRUIT GARDEN.

FILLING A VINERY IN ONE SEASON.

THERE is nothing new in filling a Vinery with healthy and vigorous rods the first season from eyes, but filling a Vinery the first year, and at pruning time cutting the rods off at the tops of the rafters, is what I have never seen recommended in any periodical. It is more than twenty years ago since I planted a Vinery in the month of June with young Vines, principally Black Hamburghs, in a border wholly outside. It consisted chiefly of loam, road grit, and, I suppose, some leaf soil, as we were not so frightened for fungus in those days as we are now. After the border was made it was allowed to settle for ten days, more or less, previous to the Vines being planted. Nor was it made to its full extent; on the contrary, only a width of 4 ft. or 5 ft. was made along the front of the Vinery. The Vines being home-grown were strong and about 6 ft. long, and in planting good wide holes were made in the border, and a few bricks were taken out beneath the wall plating in order to enable us to introduce the Vines carefully into the house. All being planted, the Vines were loosely attached to the wires in order to prevent any hanging taking place between root and top. When the Vines were planted their balls were not broken, but any roots that could be got at were stretched out and laid in the fresh soil. At this time the thermometer in the border stood, if my memory serves me, at 82°, a suitable temperature for Vine planting; indeed, it could not be otherwise, compounded, as the soil was, for the border during the warm season. On bright days the lower part of the house was slightly shaded until the foliage faced about to the light, and the inside paths, walls, &c., were kept moist through syringing with tepid water. In a short time the Vines began to grow again, apparently suffering but little from being planted in their new situations, and, with attention to airing and watering, they very soon were at the top of the house, and exhibited an amount of vigour beyond my highest expectations; and to stop the shoots in their progress appeared to me to be nothing more or less than cruelty to vegetation. I considered, too, that the more top I could get the roots would be running through the border in proportion, and upon examination I was not disappointed. Instead of pinching the shoots when they reached the top of the rafters, I simply turned the point of each shoot down the wires again to the wall plate, where most of them stopped, although some of the more vigorous ones were allowed to run in a horizontal position across the house. The bending at the top seemed to retard their growth to a certain extent, as the Vines up to this point ripened and thickened well, and by the end of the season I had an experimental house of well-ripened Vine rods, quite to my satisfaction, upon Mr. Simpson's system (p. 324). I may state that fires were continued until the end of November. In the beginning of December, at pruning time, the question arose in my mind as to what distance back I should cut the rods. As they were strong and had plenty of plump eyes, I decided that it would be worse than barbarous to cut them farther back than the top of the house; so, upon the "new plan," I filled a Vinery with strong-bearing wood the first season, independently of taking a good crop of Grapes out of the said house previous to replanting it; and neither was I disappointed with the crop the following season. The above is my experience of the so-called new plan.

During the same autumn I visited several of the best gardens I knew of, such as Trentham, Chatsworth, Enville, and others. At Enville new Vineries had been planted the previous spring, and they had made some very good wood, which was ripening well. The late Mr. Eaton showed me the hothouses himself, and I found him very communicative. In every Vinery we went through the rods were all stopped about half-way up the rafters, and apparently that had been done more than once, or from their strength they would have filled the house. In directing Mr. Eaton's attention to the matter he informed me that stopping was a system that he had long adopted in the case of young Vines. I therefore began to regret that I had allowed my Vines to stray so far from home, but still, so far, the results were satisfactory. At Chatsworth I saw a little of the new plan of fruiting Vines the whole length of their rods, but not exactly

the same as that practised by Mr. Simpson. Well-grown pot Vines were merely planted out in a narrow border while green, about 15 in. apart, and, from what I could observe, the wood was ripening well. I was informed that these Vines were intended to be fruited their whole length, which would be about 15 ft. the following season. At Trentham I was shown both the hothouses and grounds by the late Mr. Fleming, who drew my attention to everything that was new, and particularly to some young Vines which he had planted that spring, and certainly they were growing at a fine rate, but I could not say they were stronger than those which I had left at home, and, like my own, they had got to the top of the Vinery and were turned down again, while three of the leaders were progressing horizontally from opposite corners of the house, and getting on fast for 50 ft. in length. Venturing to allude to the stopping and extension system, I mentioned what I had seen at Enville in regard to stopping, and likewise what I had done myself, and, in comparing notes, Mr. Fleming's opinion was that the greater the amount of top the farther might the roots extend. Cutting back was not discussed, but, judging from appearance, the Vines were strong enough to be treated on Mr. Simpson's plan.

When I came to Workshop Manor I found the Vineries not quite satisfactory, but between pits and borders I hoped to produce sufficient Grapes till I had got young permanent Vines established, and I was not disappointed. My longest rod the first season was double the length required, viz., 18 ft. or 20 ft., and abundance of fruit was produced so long as I was at Workshop Manor, and, for anything I know to the contrary, the Vines are bearing well still, which speaks volumes in favour of the so-called "new plan." J. MILLER.

Clumber.

VENTILATION OF COOL FRUIT HOUSES.

THERE is now a good deal of fruit grown in villa and other gardens^s in glasshouses either not supplied with artificial heat, or where only just sufficient warmth is applied to keep out the frost. Such houses are usually expected to serve a double purpose—to preserve bedding plants in winter, and to produce a supply of Grapes and other fruits in summer and autumn, and sometimes, also, Strawberries in spring. This kind of fruit growing is extending, and will probably, under the influence of increasing wealth and a growing taste for gardening, continue to extend. Now it need hardly be said that the planting of fruit trees under a glass roof—though a thing to be desired from every point of view—adds to the responsibilities of those in charge, horticulturally speaking, of the establishment, inasmuch as it increases the number of living things, to whose wants daily attention must be paid. In the whole range of cultural operations under glass there are none more important than the management of the ventilation. Plants must have air, and yet air-giving is often performed in the smaller class of gardens in a very haphazard manner. One person with whom I am acquainted easily gets over the difficulty by setting the ventilators of his greenhouse Vinery open and keeping them constantly so from the end of May till the close of the season, and then complains of his Grapes being small in bunch and berry, and the crop, more or less, injured by mildew. Another keeps his orchard house closed till nearly midday, and then he cannot understand why the leaves of his Peach trees lose colour and fall off prematurely, often accompanied or preceded by the fruit, the latter being generally small and flavourless; and yet, if one looks at the matter from a common sense point of view, it ought not to be difficult to so ventilate a house containing fruit trees as to obtain a fairly satisfactory result, with the certainty that when sufficient thought has been given to the subject the work will become lighter and also be better done; hesitation or doubt as to the right thing to do will be removed by experience. In the ventilation of our dwellings we admit air on cold days in very small quantities, if at all, and we avoid cold draughts; but on warm, balmy days we set the windows open. Well, the same principle carried out in the orchard house or cool Vinery will give fair results, but not the best that are capable of being obtained, as these will easily be secured when some experience has been gained, and we begin to understand that if we carefully utilise the sunshine, we can force, so to speak, increased size into our Grapes and Peaches without spending a shilling on fuel.

If the best possible results are to be obtained with fruit in cool houses, the ventilation and the supply of moisture in the atmosphere and to the roots, if inside, must be carefully attended to. There are days and nights, too, in summer when, if the roof could be lifted entirely off, the trees would be benefited by the exposure. On the other hand, there are days often as late as June when, if air be freely given, the trees may be chilled, checked, and almost ruined. During the early stages, when the growth is young and tender, frost air should be given sparingly, if at all; cold draughts are often injurious. The presence of mildew, and all other ailments, may often be traced to a cold current of air rushing through the house early in the season. I have often thought some change might be made in

the arrangement of the ventilation of cool houses. My impression is that ventilators inserted close to the ground would be an advantage, so that the air could percolate through air bricks or some such contrivance that could easily be stopped up during very cold weather. With some arrangement of this kind there would be no necessity for any other night ventilation, and no cold draught would be created; besides, the fresh air coming in close to the ground would rise gradually as its temperature increased. I suppose no glass roof that ever was fixed was altogether air-tight, and the circulation would go on so gradually and gently that no violent disturbance of the atmosphere could take place. If air could be admitted in the way just suggested, there would be no necessity to open the back ventilators till the sun had risen and had begun to act on the glass roof so as to raise the thermometer, then, of course, the general roof ventilation would come into operation. The inserting of ground-line ventilators is becoming general in buildings where valuable animals are kept, and I believe that if the same principle were adopted in hothouses and greenhouses it would be an advantage, and would meet a want that is much felt. It should, of course, be well under control.

In the ventilation of the class of house to which I am referring in winter there could be no difficulty, as the fruit trees would then be leafless and at rest, and the more ventilation given the better consistently with the safety of the bedding or other plants that the house might contain. But when the buds burst in spring the ventilation should be reduced to a system, if the greatest possible benefit is to be obtained from the glass roof, not only as regards its protective power, but also for the forcing, or rather stimulating, effect which the climate under it will give if the ventilation be rightly managed. Unless we keep in view this latter quality we shall fail to realise the full benefits which a glass roof is capable of affording. By closing early on warm days, shutting in, so to speak, the sunshine, at the same time syringing the trees or damping the borders to create a moist atmosphere, and give an impetus to both the frail and the young growth, that will tell a tale not only upon this year's crops, but on others that follow. Early closing and early opening should form the keystone of all systems of ventilation.

Where there are no ventilators close to the ground, then the early morning ventilation must be given at the highest point of the roof. On a bright morning when not freezing, a little air should be admitted as early as six o'clock, the quantity being of course regulated according to the outside temperature. In most instances a very small aperture, at intervals of 6 ft. along the roof, will suffice, but for very early ventilation I much prefer, as I have said, the cool air entering at the ground line, where it can be carried out. With air in circulation, and admitted fresh in small quantities from the outside, the thermometer may be permitted to rise till it approaches 70°. More air must then be given, until the top ventilators are open to their full extent. If sufficient provision has been made to give roof ventilation, there will be no necessity to open the front ventilators, except when the air is genial and warm; but if during the forenoon the thermometer hanging in the house rises above 80°, with full top air on them, a little front air should be given, to be taken off again when the thermometer falls below 80°. In the afternoon the air should be reduced in like manner, until the house is closed at half-past three or four o'clock, according to the season of the year. These directions only refer to bright sunny days. If after closing on a bright day the thermometer runs up to 90°; or a few degrees more, with a declining sun, no harm will be done. Later in the season when the fruit is approaching maturity, a full and free circulation should be given both day and night, in order to give colour and flavour to the fruit; less will be required at night than during the day; still, the circulation should be maintained. E. HOBDAV.

ARTIFICIAL HEAT FOR VINE BORDERS.

As bearing out what Mr. Baines has asserted respecting the inutility of fermenting material for covering early Vine borders, and as proof, that in such an inclement season as the past, with its almost continuous frost and heavy falls of snow and wet, good Grapes may be grown without it, I send you a couple of leaves picked from Vines planted nearly twenty years ago, and which have been forced ever since and Grapes cut from them in June. Not only have these had no hot manure to stimulate the roots, a matter considered of so much importance by some, but they have not even been protected by a coating of straw and dry leaves or sheltered in any way beyond what is afforded by a dressing of rotten manure applied in autumn, and which in no part of the border is more than 2 in. thick. I think it will be admitted that the winter has been as bad as it could possibly be, owing to the absence of sunshine, and yet, as will be seen, the foliage neither lacks size nor texture, the latter quality being in some measure attributable to the low night temperature maintained, and the dry state of the atmosphere kept up at the same time, as well as

during dull days, when we were always careful to have a little air on to let out moisture caused by watering bedding plants with which the house had to be filled, as they were potted in order to give them a start. I am of opinion that more early forced Vines are injured and weakened by having the air too damp and confined than by any treatment to which the borders are subjected, for if the leaves be made thin and flimsy, they become a prey to red spider, and lack the power of enduring bright sunshine or dry parching heat during the summer. The evil of course does not rest here, as the roots are affected in an equal degree, and the strength and energy of the Vines dwindle year after year till they are unable to bear a crop that is at all remunerative or satisfactory. So convinced am I of the uselessness of applying heat to Vine borders that I have long since abandoned the practice, and the result so far has been that I have grown better Grapes than I was ever able to do with the soil weighted and sealed over with a huge mass of steaming manure. If the borders are properly drained and frost kept out by the natural means of some non-conducting material, such as fresh fallen leaves or litter, the roots will remain in a much healthier state than they will when unduly excited. This has been my experience, and if others who still go in in the old track will get out of the rut, I do not think it at all likely they will ever get into it again.—S. D. [The leaves in question measured 14 in. one way and 12 in. the other.]

GOLDEN CHAMPION GRAPE AT HENBURY HILL.

ALLOW me to tell "J. S. W." (p. 350) that on the 29th ult. Mr. Shore, the gardener at this place wrote to me saying that the berries were as large as those of full grown Hamburghs and stoning; and also that in the same house a Madresfield Court Vine, with its roots now entirely inside, though they will ultimately be allowed to run out-of-doors, is not nearly so forward as the Golden Champion, the berries not being one quarter the size. As is obvious, the inside treatment of the two has been identical, but one has its roots inside, while those of the other are out-of-doors, and the latter, the Champion, being the most forward is conclusive evidence that the roots, being outside, have neither retarded the growth nor been inimical to it in any way. If Vines started at the end of January without even protecting material on the border are too late to afford evidence as to the uselessness of hot material on the border, why does "J. S. W." use it on Vines which he admits started a month later? He fails to take notice of the cases which I have adduced of Grapes being ripe by the first of the present month without a particle of warm matter having been near their roots. With these remarks the subject, so far as I am concerned, shall close for the present. There has been, at all events, incontrovertible proof of the uselessness and very often injurious effects resulting from the use of fermenting matter on borders. "J. S. W." forgets that the roots of established Vines, such as the greater portion of those forced, have, in most cases, their best feeding active fibres far beyond the limits of the warm material-covered border, and consequently are thus beyond its influence for either good or evil. The fallacy into which "J. S. W." and others have fallen rests on the supposition that plants collectively should make simultaneous root and shoot growth; but that is a mistake. With a great number of cultivated plants, the Vine included, it is not natural for root extension to begin until a large amount of top growth has been made; and, when fermenting material is laid on the border sufficient to warm it to the extent which they deem necessary, root growth commences sooner than is either natural or well for the Vines. T. BAINES.

STRAWBERRIES ROOTING THROUGH POTS.

ALLOW me to state, in answer to Mr. Cornhill (p. 350), that allowing the plants to root through the pots previous to flowering does not cause an undue luxuriance of foliage with me, and the example which I sent to THE GARDEN Office showed this. Mr. Cornhill's statements afford no means of estimating the productiveness of his plants, and I am surprised to learn from him that market growers are obliged to confine themselves to delicate sorts if they wish to obtain good prices for their produce, and that in this respect Vicomtesse Héricart de Thury "is of but little use to market growers." Only the other week "C. W. S." informed us that Garibaldi, which is the same, was a favourite sort with a noted London market Strawberry grower, and that two other very large growers grew Sir Charles Napier exclusively, "because its fine appearance makes it a good market fruit!" but as it is not known it is an inferior kind otherwise. "Briskly acid flavour" is all the praise bestowed upon it by pomological authorities. I believe that it is more extensively grown for market purposes than any others. Your correspondent must therefore be under a delusion on this head. My experience is that private growers cultivate fruit of the first quality, and that market gardeners only second-rate, though it appears that Mr. Cornhill considers the contrary to be the case. I have often tested what was considered

fine samples of Covent Garden Strawberries in April, and I will say that more insipid fruit I never tasted, and I have often been told by those who know, that market fruit cannot be compared with home-grown fruit. The reason is obvious. Market gardeners do not and cannot take the same pains to finish their fruit that private growers take; it would not pay them to do so; hence they hurry their fruit into market as soon as it is red, whether ripe or not. I saw last year, in a noted fruiterer's window, about a dozen baskets of forced Strawberries from a London market grower, amongst which not a single berry in the whole lot appeared to be fit to gather. I certainly have never found a market grower who confined himself to varieties that were "distinguished by a delicate constitution," but they have a profound regard for the "fill-basket" kinds.

J. S. W.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Grapes from Vines Raised from Eyes the Same Year.—Allow me to assure "J. S. W." (p. 349) that I did not doubt the accuracy of his first statement under this head, but only questioned the possibility of getting anything worth calling a crop under one year from eyes. Although "J. S. W." is evidently well acquainted with the details of the system, and has experimented on planted out canes, yet he has not carried the system through to the end; therefore, he saw, I fear, little to gain by it, and the chance of a good deal to lose, as pot Vines, whether home-grown or bought from the trade, are expensive articles with which to experiment. If Mr. Henderson, of Thoresby, would kindly tell us how his Vines finished their crop, it would doubtless interest many beside myself who are anxious to get good crops in the shortest time. Although "J. S. W." says that the Vines breaking their permanent buds, owing to their leaves having been cut off, "disposes of my theory that they require a season of rest," yet that in no way alters the character or constitution of the Vine, for if checked in full growth it must needs expend its force somewhere, and naturally breaks at the eyes destined for next year's crop in the ordinary course. As, however, late Grapes and the mode of preserving them long in good condition has nearly superseded very early forcing, I do not think that many will follow so unnatural a system as that just alluded to, whether it be new or old, but will be content with treating the Vine as an ordinary deciduous subject that requires a decided season of rest.—J. GROOM.

Fruit and Garden Shelters.—Some time ago I recommended the planting of screens of Fir and similar evergreen trees for the protection of fruit gardens from the fierce sweeping east and north-east winds. How much during the last few days have such screens been wanted where Nature has made no provision for shelter! Even, perhaps, worse than the sharp white frosts of night have been the biting blasts sweeping through fruit trees and bushes with destructive results. Every spring, as regularly as the trees bear blossom, come east winds which destroy the early flowers wholesale. If some measures be not taken in time to render our gardens and orchards thus protected, fruit growing will either become an impossibility, or will be so surrounded with losses as to render it valueless. There is already too much reason to fear that generally the Gooseberry and Currant crops are much injured. Growers state that this is so, and should such prove to be generally the case, it will not only result in a heavy loss to the growers, but also to the nation. All Pears and Apples so far are yet uninjured; Plums and Cherries have been largely in bloom during the prevalence of the keen winds and frosts. What the warm sunshine during the daytime has done to promote fertilisation, the winds and frosts at night have largely undone, and in the face of such facts it is difficult to look for an abundance of the latter fruits. We must begin to realise that fruit culture in this country is no longer an easy proceeding, and that to check the damage wrought by the cold springs special shelter must be given. No fruit garden should now be planted that has not its protection in the shape of a screen of Fir trees.—A. D.

Exposing Strawberries to the Sun.—Those who have good dishes of ripe Strawberries will do well to be careful as regards trying Mr. Cowburn's plan (p. 350) of exposing them to the sun. The other morning we gathered a dish from some plants before taking them out of a Pine-house, and, as they were not wanted for dinner until night, they stood all day in a basket on a shelf exposed to the sun. At night many of them looked as if they had travelled 200 miles, and their half-fermented-like flavour was anything but agreeable, or an improvement on their taste when newly gathered.—CAMBRIAN.

Fruit Prospects in Kent.—If lateness in blooming be a desideratum, we ought to get good crops of fruit this year. With us Apples promise to bloom abundantly, but it will not be fully

expanded before quite the end of May, and late flowering kinds will open in June. Pear blossom is partial; that of Cherries generally abundant; but Plum and Damson bloom is very partial, many orchards being very thin. I may add that both on Filberts and Cob Nuts male and female blossoms are abundant, and, as they always flower when frosts are prevalent, they may withstand the extremely low temperature which they are still experiencing better than more tender fruits. Bush fruits at present promise well.—J. GROOM, *Linton Park.*

NOTES OF THE WEEK.

Camellias in the Isle of Wight.—Notwithstanding the severe winter and spring, the Camellias here are full of flowers, many of which are injured by the weather, but the shoots being laden with buds in all stages good flowers may always be found. A group in Sir William Hutt's garden shows the most freely blooming and showy plants of Camellias we have ever seen, either under glass or out of doors. They are even more vigorous than Camellias often seen about Rome. In Her Majesty's gardens at Osborne, the Camellias are also laden with flowers—and fine flowers—to a degree that is never seen under glass. Hereabouts, at least, the Camellia is not only a hardy evergreen, but the handsomest of all flowering shrubs.

Orchids at the Royal Exotic Nursery, Chelsea.—Amongst those which we noticed a few days ago in flower here was *Cypripedium Lawrenceanum*, which was finely in flower; it somewhat resembles *C. barbatum*, but it is much superior to that kind both in size and colour. The quaint-looking *Masdevallia Chimara*, with flowers triangular in outline, and measuring fully 8 in. from tip to tip of the attenuated segments, is one of the most interesting of the family. The rare *Colax jugosus* is very beautiful; its blossoms have the three outer divisions pure white, and the inner heavily blotched with deep, reddish-purple and a rich purple lip. As a rule, the majority of the *Epidendrums* are not showy, but the flowers of the new *E. Wallisi* exhibit a very pleasing blending of tints, the outer parts being yellow with here and there a dark spot, and the large lip white pencilled with purplish-black streaks, and the edges beautifully fringed. *Brassavola Digbyana* is a kind not often met with in blossom. Its flowers are white, 3 in. across, and they have a remarkably large lip, which is elegantly fringed at the edges. The best of the *Dendrobiums* now in flower are *D. Farmeri*, *thyrseflorum*, *crasinode*, *chrysotoxum*, and the handsome *D. infundibulum*, with its large ivory-white blossoms and orange-coloured lip. The gorgeous *Cattleya Mendelli* is represented by some very fine forms, differing chiefly from each other in the richness of the tints. *Oncidium concolor* alone makes a very effective display on account of its free-flowering tendency and the clear rich yellow of the blossoms, which render it scarcely inferior to the superb *O. Marshallianum*, of which there is a fine example in flower. Other rarities, such as the curious little *Phalenopsis Parishii* and *Sarcophilus Fitzgeraldi*, are also in blossom.—W. G.

Rock Plants at Oakfield.—A rockery under glass is seldom met with, but the advantage of having such a house is admirably exemplified in Mr. Joad's garden at Wimbledon. There may now be seen the choicest gems of the mountain tops luxuriating in native-like vigour, and many of them in flower. Amongst these we noticed the Siberian Saxifrage (*S. sibirica*), a handsome species which forms a tuft of kidney-shaped, toothed leaves, and bears numerous pure white blossoms $\frac{1}{2}$ in. across. Associated with this was *Ranunculus Bertoloni*, a rare South European Crowfoot with roundish leaves and snowy white flowers about the size of a shilling. Various kinds of *Androsace* were also finely in flower, notably the charming little *A. carnea* and *chamaejasme*. The creeping *Epigaea (E. repens)* here sees a quite at home, peeping from beneath the overhanging ledge of a massive boulder, and producing a profusion of its delicate bluish-tinted blossoms. Another rare Saxifrage which we noticed was *S. irrigua*, a distinct species belonging to the mossy section. It has finely divided foliage and large white flowers borne on stalks 6 in. high. These are only a few of the many interesting plants to be seen in this delightful house, in which are developed every day new objects of beauty.

Double Primroses.—We have received from Miss Owen, of Knockmullen, Gorey, Ireland, specimens of double Primroses, all extremely handsome and varied in colour. Miss Owen states that she has two distinct kinds of purple, also white, yellow, rose, lilac, and crimson. One of the crimson grows like a Polyanthus, and this form seems constant; along with these also came two double Polyanthus, a dark and light brown one, and in the same garden there is stated to be another double Primrose, white, slightly tinted with very pale mauve.

Haberlea rhodopensis.—This charming little plant is now flowering probably for the first time in this country in Mr. Joad's collection at Wimbledon. It bears considerable resemblance to a small *Gloxinia*, and belongs to the same family. It forms dense tufts composed of numerous small rosettes of leaves, which have the appearance of those of the Pyrenean *Ranondia* (*R. pyrenaica*). The blossoms are produced on slender stalks, from 2 in. to 3 in. in length, and are about 1 in. long, tubular, with a spreading mouth. The colour is a delicate violet-purple, with a faint dash of yellow inside, and copiously spotted with purple. This interesting little gem comes to us from the Balkan Mountains, where it is found growing amongst Moss, &c., on damp, shady, steep declivities at considerable elevations. Though presumably quite hardy, it is advisable, on account of its rarity, to keep it under frame culture.—W. G.

Cinerarias at Reddees.—The excellent displays of this deservedly popular flower made at the spring exhibitions by Mr. James are ample proof of his skill both as aculturist and hybridist, and a visit to Reddees equally illustrates the fact. In point of size, form, and variety of colour, Mr. James' strain has apparently reached perfection. In such an extensive collection as is grown here, of course some colours predominate, and this is the violet series, but even in these the tints are diversified by the various hues of the central florets. Associated with these, too, is a promising collection of herbaceous *Calceolarias*, which will shortly be a sight worth seeing. *Cyclamens*, which have made such grand displays in spring, are now on the wane, and their place is being taken by the *Pelargoniums*, for which this establishment has so long been noted.—W. G.

Hardy Orchids.—Several of these are now flowering beautifully in Mr. Joad's garden. They are growing in a house wholly devoted to half-hardy plants, and which evidently suits their requirements admirably. Those now in flower comprise the yellow-flowered *Ophrys lutea*, a South European kind, which has blossoms of a very curious form. *Orchis provincialis* is another yellowish-flowered sort, which has larger blossoms. The Spider Orchis (*Ophrys aranifera*), one of the most variable of Orchids as regards the colour and size of its blossoms, is here represented by numerous forms; also the apparently nearly allied *O. arachnites*. *Orchis longibracteata*, one of the largest-flowered Orchises, has its blossoms, which are of a pale violet-purple tint, produced in long dense spikes. Last, but not least, we noticed the very rare Northern *Calypso* (*C. borealis*), a North American species with rather small flowers, possessing a remarkably curious structure somewhat resembling a bull's head.—W.

Greenhouse Rhododendrons.—The following kinds of tender Rhododendrons are now finely in flower in Messrs. Veitch's nursery, Chelsea, viz., *R. Countess of Haddington*, a kind with large funnel-shaped flowers, varying in colour from a delicate blush to a deep rose tint; *R. Sesterianum*, with large pure white blossoms, having crisped edges; *Princess Alice*, with white flowers, which are more shallow than those of the others; and *R. fragrantissimum*, also a large white-flowered kind, and, like the preceding, exhaling a delicious perfume. All these, and many others of a similar type, make capital showy plants in greenhouses in spring, and should be more extensively grown than they now are.—W.

Clematises at Chelsea.—One of the conservatories in Messrs. Veitch's nursery is now gay with well-flowered plants of Clematis, chiefly those of the patens type. They are trained on balloon-shaped trellises, which are covered with flowers of various hues, and exceedingly effective when seen mixed with other spring-flowering plants. As they are so easily managed under pot culture, they certainly deserve to be more extensively grown than they are for conservatory decoration.—W. G.

Spirea Thunbergi.—This is one of the neatest spring flowering shrubs with which we are acquainted. It rarely exceeds 2 ft. in height, and is for a considerable time literally covered with small white blossoms, which, seen *en masse*, are remarkably attractive. Though perfectly hardy, it is an excellent plant for conservatory decoration, as it succeeds admirably in pots.—G.

The Cluster-headed Polemonium (*P. confertum*).—This singularly beautiful species, of which we gave a coloured illustration (Vol. XIV., plate 48), is now finely in flower in the open air at Mr. Parker's nursery at Tooting. Though it is reputed to be difficult to manage, it seems to thrive admirably in a thoroughly drained position, and where excessive moisture during winter is prevented as much as possible.

Mesospindium sanguineum.—We saw a fine display of this beautiful Orchid a day or two ago in Mr. Parker's nursery. The Grass-like foliage and the gracefully-arching spikes of deep rosy-red blossoms were very effective. Associated with these was a good batch of the rose-coloured *Odontoglossum* (*O. roseum*) in fine flowering condition, which was also very attractive.

Rose Medals.—The Société Centrale d'Horticulture of France, dealing with the special gift of Madame Laffay, widow of the eminent Rosarian, to be distributed to Rose growers who had raised the best varieties of Roses, has decided that a gold medal should be given to F. Lacharme, a gold medal to Guillot fils, and one silver-gilt to Madame Ducher—all three of Lyons.

Pulmonaria dahurica.—A fine flowering example of this rare little Liverwort may now be seen in Mr. Parker's nursery. It grows about 6 in. high, is spreading in habit, and has small lance-shaped leaves and dense terminal clusters of deep blue blossoms. It apparently requires a little protection during winter in order to bring it to perfection.

Saxifraga aretoides primulina.—When this charming variety is seen by the side of the type the distinction is very marked, as the blossoms, instead of being of an orange tint, are of a clear primrose yellow. It also seems to be much dwarfer in growth and more dense.—W.

Muscari pallens.—This is an elegant little kind not often met with. At first sight it reminds one of the pallid form of *M. botryoides*, but it is readily distinguished by the flowers not being globose, as in the latter, though the colour is much the same. It is now flowering freely in Mr. Barr's grounds at Tooting.

Masdevallia Shuttleworthi.—An unique specimen of this very singular Orchid is now in flower in Mr. Bull's nursery at Chelsea. It is by no means so showy as many of its congeners, as the marking of its flowers is somewhat of a dull hue, but on account of its extreme rarity it is particularly noteworthy.—W. G.

Tulipa Greigi.—Some of the best flowering examples of this fine Tulip which we have yet seen are now in Mr. Joad's garden at Oakfield, where, in company with other choice hardy bulbous plants, it thrives admirably.—W. G.

NOTES FROM KEW.

Hardy Plants.—The various representatives of the showy Borage family are particularly noteworthy, the rarest amongst them being the beautiful *Echium*-like *Arnebia* (*A. echinoides*), with clusters of bright yellow blossoms $\frac{1}{2}$ in. across with five spots at the base of the divisions of the corolla, which are black, gradually fading to a pale brown tint. It is perfectly hardy, and succeeds admirably when planted on well-drained rockwork in a partially shaded position. Boissier's *Kernera* (*Kernera Boissieri*) is a very neat little novelty for the rockery. It grows about 3 in. high, tufted in habit, and at this season forms a perfect compact mass of small white blossoms, which remain a considerable time in beauty. It is a member of the Crucifer family, and of perennial duration, and, as it produces seeds very freely, we hope to see it more widely circulated. The North American *Trillium* are always worth referring to, as they comprise some of the most ornamental of bog-loving plants. The large-flowered kind (*T. grandiflorum*) is a superb species, and should be in every collection; the rich green of its trifoliate leaves and the chaste beauty of the large pure white flowers render it highly attractive. It abounds in various parts of North America, growing in shaded, moist localities. Another handsome North American plant is the large-flowered *Uvularia* (*U. grandiflora*) belonging to the Lily family. It grows about 15 in. high, with stems about the size of a quill, the upper part of which gracefully droops, bearing the yellow blossoms, which are 2 in. long, with narrow segments. As a choice border flower it ranks high and deserves to be better known. *Corydalis nobilis* is amongst the best of its family; the dense clusters of yellow flowers, rising from the finely-cut glaucous foliage, are very attractive. *C. bracteata*, like the preceding, is a native of Siberia, and differs from the last by the unusually large size of the floral leaves; the blossoms are about the same size and colour. Amongst the bulbous plants a charming variety of the Rush-leaved Daffodil, named *Narcissus juncifolius* var. *apodanthus*, is a very distinct kind, and may at a glance be distinguished from the type by the larger and richer coloured blossoms, and the cup being much shallower and lobed. It is a native of Spain, and as yet seems to be somewhat rare in collections. The Crocus-flowered *Romulea* (*R. crociflorus*) is a very handsome Irid, which, when its flowers are fully expanded, strikingly resembles those of the old *Crocus biflorus*, as they are about the same size, and possess the same lemon tint inside the perianth.

Greenhouse Plants.—*Boronia elatior* is showiest and most graceful of Australian hard-wooded plants, and makes a very fitting companion to its deliciously-scented congener, *B. megastigma*. It grows into a compact bush, with numerous slender branches and small leaves interspersed with a profusion of rosy-pink globular flowers, which are also sweet scented. Some of the original species of *Pelar-*

PLATE CLXXIX.

TYDÆA ROBERT LE DIABLE.

Drawn by CONSTANCE PIERREPONT.

goniums, which chiefly inhabit the Cape of Good Hope, are extremely beautiful and certainly merit more extended culture. P. Schottii perhaps possesses the richest coloured flowers of any; they are deep magenta with a conspicuous black-purple blotch on each petal; the foliage, too, is ornamental, as it grows to a large size when liberally treated. A remarkable Aroid is *Arisema præcox*, which has large, thrice-divided leaves and mottled stalks. The flowers are very curious, consisting of a membranous spathe of peculiar form, elegantly striped with green and dark brown, enclosing a cream-coloured club-shaped organ. *Pentlandia miniata* is a very desirable *Amaryllid* with a stout flower-stalk rising from an oval-shaped bulb, and bearing several pendulous, tubular blossoms $\frac{1}{3}$ in. long and of a bright red colour. The well-known *Scutellaria Mocimiana*, which is usually met with in stoves, is made free use of in the greenhouse, and a capital plant it makes for the purpose; the bright scarlet clusters of flowers have a telling effect when mixed with more delicate-tinted kinds. The plants are grown in heat and gradually inured to a lower temperature.

Stove Plants.—The *Cotinus*-leaved Dais (*D. cotinifolium*) is a rare and interesting African shrub, belonging to the *Daphne* family; the leaves are rather small and oval, and the flowers are produced in dense clusters, similar to those of *Pinus*, and are of a pleasing violet-purple tint. *Tabernaemontana coronaria* is a pretty shrub, of neat habit, studded with numerous Periwinkle-like blossoms, which are pure white with a golden eye. The double-flowered form of this species much resembles the ordinary *Gardenia*, and is a capital substitute, though it is not so strongly scented. The roof of the old Lily House is now extremely gay with that lovely climbing Brazilian plant, *Bougainvillea speciosa*. This kind differs from the better known *B. glabra* by its larger floral leaves and by the hairy leaves. For planting in houses where room can be spared this superb plant cannot be too highly recommended. Among the *Bromeliads* the variety *pauicifolia* of *Billbergia Wetherillii* is now very attractive, the deep carmine bracts and the indigo-blue flowers, borne in gracefully drooping clusters, need only to be seen to be appreciated. Another handsome member of the same family, and one that retains its beauty for such a considerable period, is *Æchmea glomerata*, a Brazilian kind, with scarlet bracts enclosing rich purple flowers, collected into very dense clusters at intervals along the flower-stems, which rise 18 in. high.

Orchids.—The Long-tailed Lady's Slipper (*Cypripedium caudatum*) is probably the most curious of this vast family. The flowers are arranged in a racemose manner on a long flower-stem, and consists of a pouch-like lip as large as a pigeon's egg of a greenish-purple hue; the two side petals are developed to an enormous length, in some measuring nearly 2 ft., and twisted more or less in a spiral manner. The variety *splendens* is an improvement on the original, as the flowers are larger and the tints better defined; they are, as indeed are all the species of this section of the genus, natives of the warmer regions of South America. *C. Hookeri* is a desirable Bornean species with mottled foliage and blossoms, with the lip greenish, and the tips of the side petals of a rich violet-purple. *Dendrobium Jenkinsii* is a pretty little kind for growing on blocks, to which it readily attaches itself, and for several weeks at this season is highly attractive by the numerous rich yellow flowers which spring from the small bulbs. Much resembling it in point of size and colour of the flowers is the old *D. chrysotoxum*, one of the best of the late-flowering *Dendrobiums*. Nothing can well exceed the rare beauty of some of the *Aerides*, and the Fox-brush Orchid (*A. Fieldingii*) is one of the best; the long, dense racemes of delicate lilac-tinted blossoms very aptly suggests its popular name, and which, combined with their delicious perfume, renders it very desirable. The best of the *Odontoglossums* now in flower is *O. Cervantesii*, with flowers $\frac{2}{3}$ in. across, pure white, with the centre prettily marked with bars of rich chocolate colour. *Harrison's Oncidium* (*O. Harrisonianum*) is a very neat-growing kind with glaucous foliage, and a long spike of small flowers yellow barred with dark brown. *Masdevallia ignea* is a very showy and free flowering kind of the *Veitchii* section. The blossoms are large, with attenuated divisions, the upper one bending over the face of the flower in a peculiar manner. The colour is orange-scarlet striped with lines of a darker hue.—W.

Gardenias in Small Pots.—These are most useful when grown in small pots, such as 4's or 32's, for house-decoration. Some plants of these here, fifteen months old, from cuttings, had from ten to fourteen blooms on each, grown in 48-sized pots, which in this case are more useful than when all the stock consists of large plants, and for putting in vases, baskets, &c., in rooms they are most useful, and will be sure to be appreciated, as most people like *Gardenias* on account of their fragrance and form. The ease with which they may be grown brings them within the reach of all who have a warm house, and they well repay any trouble they may have bestowed upon them.—J. C., Farnborough.

Few plants are more easily grown or produce flowers in greater profusion than the *Tydeas*. With a little care in their management during the spring months, a constant succession of their showy blossoms may be ensured for conservatory decoration throughout the whole of the summer when most other flowering plants will have become impatient of being under glass. The plant from which our drawing was taken continued in flower at the Pine-apple Nursery, Maida Vale, with but slight intermission from July until October in last year. *Tydeas* may be divided into two sections, viz., those which die down, like the *Achimenes*, and those which, although they require a period of rest, resent one of too long duration or too severe a drying off. As, however, through intercrossing, these two sections have become difficult to distinguish, the best way, perhaps, is to treat the whole as plants only requiring a partial rest. After they have finished flowering, therefore, they should be placed on a shelf in a greenhouse in which a temperature of from 45° to 50° is maintained throughout the winter, keeping them in the same pots in which they flowered, and giving them a little water now and then, being guided in the quantity to be given to each by the appearance of the leaves. Those plants which seem the most lively and green should have the most water given them, and in this way they should be kept until the middle of February, when they may be removed to a shelf in a warm house, and shortly after divided and started into growth in small pots. As the season advances and the plants become vigorous, they should be potted onwards, until they are in the pots in which they are to flower. The best compost to use for *Tydeas* (or, indeed, any other Gesneraceous plants) is a mixture of one-half turfy loam, one-fourth fibry peat, and one-fourth dried cow manure rubbed fine and well mixed with the other materials. The chief points to be observed while *Tydeas* are growing is to keep them always in a genial temperature, and in a place where cold currents of air cannot reach them. In June and July, when the buds begin to show colour, more air may be given, and as soon as the first flowers expand the plants should be placed in a sheltered part of the conservatory or greenhouse, where they will continue to bloom long after dull weather has set in. A few of the best kinds are—*Robert le Diable*, well represented in the annexed plate; *rosea*, pink spotted with dark rose, and dwarf in habit; *gigantea*, yellow spotted with scarlet; *Vesuvius*, red, spotted and lined with maroon; *alba kermesina*, white and rose; *Pericles*, vermillion, yellow and crimson; *tricolor*, coral and white, spotted with rose; and *venosa*, magenta violet, spotted with purple.

JAMES O'BRIEN.

RASPBERRY-LEAVED PELARGONIUMS.

SWEETNESS and elegance, combined with such freedom of growth and vigour of constitution as permits, without injury, foliage and flowers to be out in abundance, will always render this *Pelargonium* a favourite; there is, moreover, a smaller variety of it, the leaves of which, from their minute sub-division, are exceedingly elegant. Both kinds grow freely, especially when planted out either in the open air or in the greenhouse or conservatory. They are well adapted for planting against a wall or pillar in some light situation under glass, as the growth in such positions is very rapid and continuous, and, though their lilac flowers are small, the successional way in which they are produced for several months—commencing early in the spring—adds much to their value. I think, from what has come under my own observation and the information I have gleaned from others, that the variegated *Pelargonium* called *Lady Plymouth* must be a sport from this variety. If my information be correct, this must have occurred some fifty years ago. I have often seen green shoots on plants of *Lady Plymouth*; in fact, we have several now that seem to be identical with those of the *Raspberry-leaved* kind (*P. Radula*). One need say but little about its culture, as a plant that has held its own for so many years, when so many of its contemporaries, introduced about the same date, have disappeared, requires no special treatment. It is just the plant for the cottage window, or to plant out in summer in the little border in front of the cottage.

E. HOBDAV.

Double Sulphur-coloured Primrose.—This is a charming variety, and one which lasts a much longer time in perfection than the original; and, being even more floriferous, it is a decided acquisition either for pot culture or for planting in the flower border, on banks, by the margins of woodland walks, and similar places.—W. G.

GARDENING FOR THE WEEK.

Greenhouse.

In order to keep up a continuous supply of flowering plants for conservatories and greenhouses, it is necessary to be continually providing subjects, which, though of minor importance, nevertheless, fill up the gap that intervenes between the blooming of the groups of plants that afford the chief display throughout the year, and without which, especially during the late summer and autumn months, there would be sure to be considerable deficiency.

Abutilons.—These almost incessant flowering plants now exist in such variety, and are so dwarf in habit and free blooming that they will flower even in very small pots. Young plants of them potted now and encouraged to make growth will, four months hence, have attained a useful size, keeping them stopped, as occasion may require, in order to lay the foundation for a bushy form, which will, in the majority of cases, be found the most useful. The stopping thus recommended by removing the points of the shoots with the newly-formed undeveloped flower-buds will induce the plants to make growth instead of flowering till they are required. By way of variety, and to assist effective arrangement, a few of them may be grown as standards, dwarf, or of medium-size, according as they may be found most suitable for the description of structure wherein they will have to be used. As has been already said, these plants are being raised in such immense quantities from seed that to give names would be useless; it will be sufficient to say that they exist in various shades of colour, from the deepest dark crimson through the paler hues of red down to yellow and white, and the plants are as different in habit as they well can be from the species first introduced.

Petunias, Single and Double.—At no season of the year are these so useful as late in summer and autumn; blooming, as they do, in the smallest state, and continuing to flower on up to the end of the year with very little attention, they deserve to be grown in quantity to come in about the time mentioned; they will be found especially serviceable, for when done with all of them can be discarded, excepting a store pot or two of each variety, which should be retained for purposes of propagation, a great advantage, as in winter most of the space allotted to greenhouse subjects is needed for plants of a more permanent character. Cuttings put in a few weeks ago and now rooted—kept three or four together in 6-in. pots in light rich soil, and moved into others 2 in. or 3 in. larger when necessary, keeping them sufficiently stopped to have them compact, and picking the flowers off till within a month or so of the time when they are required in bloom, and the shoots kept in position with a few light sticks and ties—will be most useful. Many of both the double and single sorts are well worth cultivating; the latter, consisting of beautiful and distinct colours, are now raised from seed, and yield an abundant amount of variety. Either the double or single kinds will do for hanging baskets, but the single being usually of a weaker and more procumbent habit, are better suited for the purpose than the others.

Amarantus and Balsams.—Young plants of the old-fashioned Cockscorn, the small Globe Amarantus, and Balsams should have every attention. They need plenty of light, and root room sufficient to enable them to get strong and vigorous in their early stages, otherwise their effective appearance when in flower will be much diminished. A few more seeds may now be put in with advantage to produce plants to bloom later on. In most places little difficulty after this time will be experienced in accommodating all such plants as those just named, for ordinary frames and pits—in which they will grow much better during the summer than in houses—will shortly be at liberty and ready to receive them.

Schizostylis coccinea.—This is another plant that deserves to be grown in considerable quantities by every one who possesses a greenhouse or conservatory. It is one of the finest late-flowering plants which we have out-of-doors, where it can be protected a little; but, when properly treated, it is even more useful for conservatory decoration. It may be managed in two ways, either planted out in rows or clumps in the open ground, in good moderately light soil that will admit of its being lifted in the autumn for potting without the breakage of root fibres, which inevitably happens when the land is of a heavy, close nature; or it may be grown in pots, six, eight, or a dozen together, according to the size of the pots, which may be from 7 in. to 10 in. in diameter. Each method has some disadvantages; but, on the whole, I prefer pot culture, provided the plants are properly attended to during summer with water. With all plants that require similar treatment to this it is requisite to urge the necessity for this attention, as, if allowed to suffer from want of water, they get so enfeebled as not to produce nearly their full complement of flowers. To avoid this I should recommend the pots to be plunged

in coal ashes or loose earth, set in an open position, and supplied with water often enough to prevent the soil ever getting dry.

Tritonia aurea and its Varieties.—For late summer and autumn greenhouse decoration these plants are equal or superior to many that require a great deal more attention; those who have only seen the common *T. aurea* can have no idea, fine as that kind is, of the effect produced by an association of the varieties of different colours as they now exist, from white, orange, buff, salmon, to red and crimson. For those who have not grown them I may say that for cultivation in pots they need little different treatment from that usually given to *Lilium speciosum*, except, that being so much smaller growing, they require proportionately less room, and may be grown in large numbers together in much smaller pots; but as to soil, potting, treatment from the time they appear above the soil in the spring through the summer up to the blooming period, and also when at rest in the winter, the management that suits *Lilies* will do for them. They must be kept free from slugs and snails, as these pests have such a liking for the leaves, that they riddle them completely, a mishap which has an injurious effect upon the blooming and greatly impairs their appearance.

Lilies.—Nothing is more useful for conservatory and greenhouse decoration than the autumn-blooming species of these plants, for which purpose, independently of their other merits, they deserve special attention. If, amongst plants of *Lilium auratum* a few exhibiting a disposition to bloom later than the others be picked out and marked, they can without any undue amount of retarding, be made most serviceable for the decoration of the greenhouse and conservatory in autumn. Then there are all the different varieties of *L. speciosum* that may by similar treatment be induced to come in at the same time. If a portion of the plants be now put at the north side of a wall, but not too much shaded or treated so as to chill them, until the weather gets warmer, they will afford a succession of flower after those more fully exposed to the sun are over.

Gladioli.—Few plants are more acceptable in the conservatory than these late in the season after the weather outside is such as to prevent the possibility of their flowers opening satisfactorily. They may be had in bloom in quantity in pots up to Christmas, but to come in at that time the planting should be delayed until June. If a small piece of reserve ground can be spared for them well prepared, and made moderately light, they may be lifted and potted when their bloom spikes are formed late in the autumn before sufficient frost has set in to destroy them; doubtless this very late planting is not conducive to the well-being of the plants, and it might be urged on that account that the practice is not good, but effective varieties are now so cheap that they can be had for 2s. or 3s. a dozen or less, and even if after a single season's treatment such as this they are found useless, which is not likely to be the case, their culture would still be more economical than Hyacinth-growing, for beautiful and indispensable as Hyacinths are, they are individually much less effective than the Gladioli.

Vallota purpurea.—This free-growing and brilliant-flowered bulbous plant is one of the best of autumn decorative subjects which we possess. It is often grown with a little extra warmth in spring in the way in which the Amaryllises are treated. Where some are wanted to come in earlier than usual such treatment has the effect of inducing them to do so, but where they are wanted late, as is the case with the plants I am now particularly mentioning, they should be treated on the cool system, as in an ordinary airy greenhouse, but fully exposed to all the sunlight available; so managed, when the plants are strong they will produce a succession of flowers till the autumn is far advanced.

Tuberous-rooted Begonias.—For blooming through the autumn months a good number of these should be grown, selecting those that are the most distinct in colour. They soon acquire a useful flowering size, and if small-blooming bulbs be now at hand in 3-in. or 4-in. pots, keep them growing until towards the end of the month, when they may be turned out in a full open situation in light, free soil with just as much support in the shape of sticks and ties as the particular habit of individual plants are found to require. They should be well attended to with water, transferred to pots at the beginning of September, and kept at a little above an ordinary greenhouse temperature. Thus treated, they will bloom satisfactorily. Where a sufficient number of larger plants exist, they may be kept in pots proportionate to their size, placed for a few weeks in a pit or frame, and then have their pots plunged out-of-doors, stopping them once or twice during the season to induce a close enough habit, and they will keep up a complete mass of flowers through the autumn. For general decorative purposes, some of the less perfectly formed flowers from the florist's point of view—that is, those that have longer, narrower petals—are more effective, and have a more elegant appearance than the rigid, stouter-growing kinds.

Plumbago capensis.—This very distinct old-fashioned plant should be grown in considerable numbers by those who have to keep up a succession of flowers. For late blooming, and to succeed the plants that come in with ordinary greenhouse treatment, a portion may now have their shoots stopped, and in the course of another week or ten days be plunged out-of-doors in an open situation, where all that they will require is their shoots being trained, so as to prevent their getting into a straggled condition, and sufficiently supplied with water. In cases where the plants are furnished with roots enough to fully permeate the soil within the pots, manure water may be given once a week; this will have the effect of inducing a stronger condition of growth, which will have a natural tendency to further retard the formation of flowers, an object which it is desirable to attain, in order to induce as late a disposition to bloom through the autumn as possible.

Swainsonas.—These handsome pea-blossomed plants, although not naturally inclined to flower so late in the autumn as some subjects, may be easily had in bloom during September and October. Small specimens in 8-in. or 10-in. pots, are more useful than larger examples. They will be growing away freely now, and if the whole of the shoots, weak and strong, have their points pinched out about the end of this month, it will make them bloom later. The foliage is liable to the attacks of red spider if not kept syringed during warm weather, but if the water be applied freely once a week, so as to reach the under sides of the leaves, it will be sufficient to keep them in good condition. In the case of most plants that have a tendency to suffer from attacks of this insect, they can be well accommodated in a light span-roofed pit, where they can stand on a floor composed of ashes, sand, or any moisture-holding material, it will be found much more conducive to their general well-being than shelves or wooden or stone stages, from the continual moisture that the former are always giving off, especially when most needed, during the hottest parts of the day; and on a cool, moist bottom, such as described, the work of watering will be considerably reduced.

Witsenia corymbosa is one of the best hard-wooded plants for blooming during the latter months of the year. It is of very easy culture, yet seldom seen, requiring no training or support in any way; the flowers are a beautiful blue, equal to the brightest of the *Myosotis*, continuing a long time in good condition, and though not produced in such quantities, or of a character that will permit of their being used in a cut state to the extent of some flowers, yet, from the distinct character of the plant and its flowers collectively, it associates well with anything else. It is a slow grower, and suitable for either a large or small house. It requires a sandy peat soil, and treatment in other respects such as the less tender of evergreen hard-wooded subjects. Where provision is now made with the plants I have above mentioned, there will be no cause for the complaint so often heard that greenhouses and conservatories through the summer and autumn months contain few flowers possessing interest or distinctive character.—T. BAINES.

Flower Garden.

Though the bedding-out season, so far as dates are concerned, has arrived, suitable weather has not yet set in, and till this occurs and the weather becomes warmer, the planting out of anything of a tender nature had best be deferred. All hardy plants should be got in forthwith, and the places marked out and prepared for tender ones, in order that there may be no unnecessary delay as soon as it is safe to plant them; meanwhile continue to propagate *Alternantheras*, *Coleuses*, and *Iresines*, which cannot be planted too thickly together if they are to be effective from the first. *Pelargoniums*, *Lobelias*, *Petunias*, *Heliotropes*, and similar plants ought now to have full exposure, except on frosty nights, when canvas or mat coverings will be requisite and sufficient. Seedling bedders, such as *Ricinus*, *Wigandia*, *Solanum*, *Cannabis*, and *Ferula*, must still have [the protection of a cool house or pit, and be afforded plenty of space to induce sturdy growth. As these cannot be planted with safety till the first week in June, if they are likely to get pot bound, they should be at once shifted into larger pots in order that no check may be given to the plants, as that causes premature flowering or fruiting, which, as a matter of course, hinders that noble development of foliage which has made them so popular as easily raised sub-tropical plants. If I were desired to name the class of plants that have the most pleasing, most effective, and most lasting characteristics as bedders I should answer succulents; I know that they are not popular bedding plants, but I believe that they will yet occupy a prominent position, and that the gaudy, short-lived effects now obtained through the use of *Pelargoniums*, *Calceolarias*, &c., will be suppressed. The following list contains plants all suitable for bedding purposes, which if well arranged with dwarf *Sedums*, *Saxifragas*, and variegated *Mesembryanthemums* as undergrowths or groundwork, the result will be so satisfactory as to convince the most sceptical of their utility; their names are: *Agave americana* and *A. americana variegata*,

Yucca aloifolia variegata, *Sempervivum arboreum*, *S. arboreum variegatum*, *S. physaloides*, *S. canariense*, *S. Donckelaari*, *Cotyledon pulverulentum*, *Pachyphytum bracteosum*, *Kleinia repens*, *Eleocharis metallica*, *E. glauca metallica*, *E. agavoides*, *E. Peacockii*, and many others. Occasionally succulents are used intermixed with the ordinary kinds of bedding plants, but in my opinion such association is sadly out of place. Being such totally different types, the two classes should, at least, be planted in separate beds. Of course there is no good reason why the beds should be entirely isolated; rather the contrary, in order that comparison as to merit may be easily made; and if refinement and lasting properties are to win, the succulents will gain an easy victory. The heavy rain and snowstorms which we have had have hardened the surface soil of herbaceous borders and spring flower beds; and now that drier weather has set in this should be stirred with a hoe or small fork, to prevent cracking and to destroy weeds. Pyrethrums are now throwing up their flower stems and should be staked, as should also other plants that need support. Any vacant spots in such borders should be filled up by planting in showery weather any spare annual flowering plants which there may be at hand, or they may be sown in position, and if done at once, the following will flower profusely by August, viz., Sweet Peas, Lupins, Scabious, Schizanthus, Nemophilas, Larkspurs, and Candytufts.—W. W.

Auriculas.—Allusion was made last week to repotting collections of these; we have begun to do ours. This is a matter requiring some care. Many varieties of the choicest descriptions have a tendency to rot at the side of the stem, or at least become affected by a dark spot, which spreads until the plant is destroyed. When it is first perceived it should be cut out and the clean portion dusted with quicklime; after potting these care must be taken not to give too much water. The long tap root must be cut off short, as the plants do best when the roots are kept in a compact mass near the surface of the pots. If it be intended to save seeds plants bearing seed-pods must not be repotted, but be placed, if possible, behind a north wall. I like to give such plants plenty of air night and day, allowing the sun to shine upon them early in the morning and after two p.m. Pay attention to small seedlings yet in the seed pots; as soon as they are large enough let them be potted off, and those that had been potted off in the autumn will now require to be repotted. Either place one plant in the centre of a 2½-in. pot or three round the sides of a 3-in. one. Owing to the cold weather which we have had the flowers have lasted a long time. We have at least 200 plants yet in full beauty; these must be kept cool by airing the house or frames in which they are placed freely, and shading them from the sun.

Carnations and Picotees.—Plants of these will have to be placed out-of-doors next week, probably; but before doing so, it is desirable to fumigate the frames in order to destroy green fly, which to Carnation growers, is a troublesome insect. As the weather has been dry for some time, and promises to continue so, it would be a good plan to mulch the surface of the beds and borders, but we would not water until the nights are warmer. There can be but little growth while the thermometer at night falls a little or slightly above the freezing point.

Hollyhocks.—If plants propagated in spring are not yet planted out, that should be done at once; they will flower with the Dahlias in September. Plants out and growing should be mulched, but do not water, unless it is absolutely necessary, until the nights are warmer.

Pansies.—We cannot boast much of the growth of plants of these put out into borders; they do not seem to like the dry east wind which has so long prevailed; nevertheless the plants look healthy, and fortunately are yet free from greenfly. Plenty of blooms can now be obtained from plants in pots. See that they do not suffer from want of water, and give manure water at every alternate watering. Air the frame freely and pick off old flowers and leaves as soon as they show signs of decay, and arrange the plants so that they may present a pleasing effect.

Hardy Primulas.—The directions given for the culture of *Auriculas* generally apply to these. They are plants that cannot bear neglect; and it is better to plant them out in a border and let them take their chance than allow them to suffer in pots through lack of air and water. *P. amena* and its varieties are now in full beauty in cold frames. They are much too fragile in leaf and flower to be planted out of doors. The trusses of flowers must be supported with neat sticks, and liberal supplies of water must be given at the root.

Tulips.—We have had the ground between the rows stirred with a small hoe, and after doing that a second time, a mulching of rotten manure will be placed over the roots. This ought to have been done a week or two ago, but the weather has not been such as to render it quite necessary to do so. We do not think the flowers will be so good this year as they generally are. Glass lights should now be

placed over them, but in our own case it is not yet convenient to use them for this purpose. Coverings should be placed over the beds every night to protect them from frost, removing them about eight in the morning.—J. DOUGLAS.

Hardy Fruit.

Up to the present time fruit prospects are good, but unless a decided change in the weather occurs very soon, the season will be too short to mature some varieties, even if they escape the sharp frosts which we are still having nightly. All coverings must still be continued, but any of a movable character should be taken off for at least a couple of hours each day. The foliage of Pears and Plums on walls will soon be sufficiently developed to be ample protection for the young fruit, and as soon as this is the case, all other protecting material should be removed. Peaches on well-protected walls have set fine crops, and are now ready to disbud, an operation which we prefer completing now whilst the buds are small, when time can be afforded to do so. If neglected, or the buds are allowed to get large, then, of course, it is best to disbud partially only, completing the operation by going over the trees three or four times at intervals of a few days, as the removal of so many large shoots at once would seriously check growth, and probably induce canker, gumming, or other organic diseases. Carefully examine the trees daily, as at this season and stage of growth green or black fly is almost certain to attack them, and any delay in the application of remedies makes the battle harder to win. Probably open-air Grapes will this year be a failure in the most favoured districts, for the Vines even now have barely started into growth; still, the usual cultural treatment must be given them as a foundation for next year's fruiting. Disbud them very early; it is not necessary to wait till the embryo fruit can be distinguished, as all the "shows" or open-air Vines are generally alike, and the only selection required is to distribute the fruit as evenly as can be done over all parts of the Vine. Rich surface-mulchings and a watering with liquid manure when the fruit is commencing its second swelling produce, in the south of England, Grapes which will bear comparison with those from ordinary greenhouses. Figs, too, will be late, and many will not ripen, except in the most favoured districts. Laying in the branches thinly, so that the fruit may be fully exposed to sunshine, will doubtless conduce to earlier ripening. Pinch out or press at the third leaf the points of all new shoots, and, if necessary, in order to prevent overcropping, entire shoots may be taken out. Constant repression of growth by pinching is a necessity as regards fruitfulness in the Fig, more particularly if the root-run be not circumscribed. With us Gooseberries and Currants are likely to be very heavy crops, and doubtless this is general. As a preventive of caterpillar it will now be advisable to sprinkle under the bushes, or, better still, the whole ground with quinine. Cuttings of these that were put in when the trees were pruned should now be looked over for the purpose of rubbing off superfluous eyes or buds. Each tree should have a clear stem, say about 9 in. above ground, and if about three of the topmost shoots be retained, and the points stopped two or three times during the summer, by the autumn bushy little heads will be formed, and many of them will be good enough for permanent planting. Vigorous growing young trees will be improved both in appearance and fruitfulness if the leading or strongest-growing shoots be stopped a time or two during the growing season.—W. W.

Parks and Open Spaces.

Avenues.—Trees in avenues, so long as they need artificial supports, require attention, in order to prevent their being injured by too tight ties. Tying loosely is an evil in the opposite direction, which must also be guarded against. Attention should likewise be paid to watering during the early stages of the development of the foliage, and in the case of trees which show signs of weakness, a little manure water should be added, or the trees should be mulched. The soil at the base should be frequently moved in the case of those on the margins of roadways, but not so much so as to injure the roots.

Shrubberies, Plantations, and Borders.—On dry warm days the hoe must be used where weeds make their appearance. In herbaceous borders plants requiring supports should have them; growing kinds, and aid in fully developing the flowers. Annuals should be kept free from weeds, and thinned out where necessary. Many kinds which have been grown in frames, such as Stocks, Asters, Zinnias, &c., may now be planted out, choosing showery weather for the operation; the same observations apply to perennials from the nursery beds. Seeds of nearly all kinds of annuals, biennials, and perennials may now be sown.

Flower Beds.—As spring flowering bulbs go out of bloom they should be taken up and laid in sandy soil until they have ripened off, when they may be sorted and stored away in a dry airy

place until the time for planting has again arrived. Pansies, Daisies, Aubrietias, and many other spring bedding plants will continue flowering until the time arrives for putting out summer bedding plants; but all beds which can be cleared should be prepared for other plants by manuring, digging, or by adding fresh soil where necessary. They should be ready by the second or third week in May, when, should the weather be favourable, the great bulk of bedding plants should be ready for planting out. In the case of Pelargoniums, Calceolarias, Ageratums, and similar plants, especially where large quantities are needed, as is often the case in public parks, it is by far the best plan to have them potted singly. Lobelias, Pyrethrums, &c., may be wintered in pots, pans, or boxes, and watered, if necessary, as soon as planted. Watering, indeed, should continue until rain falls, and must be done in the morning and evening, never in the middle of the day, as it injures the plants and hardens the surface of the ground. After rain, the hoe should be lightly used among the plants, or, what is better, the beds should be forked over with a small hand-fork.

Lawns and Grass Plots.—Grass should be rolled about three days before it is mown, and again directly afterwards; edges of beds and verges should be neatly clipped with shears or cut with the edging iron. Any subsidence in newly made plots should be at once remedied. In every case where it is necessary to lift and relay turf, immediately it is down it should be thickly covered with fine rich soil; the unsightliness of this for a few days will be amply rewarded by the Grass being saved from burning, and by its becoming green in a much shorter time than when it is left bare, as is too often the case; moreover, it fills up any interstices which may be left, and acts as a fertiliser. It is also advisable to sow about two bushels of seeds of fine lawn Grasses per acre at the same time, lightly raking over the surface; it may then be left for a few days, raked over again, and thoroughly rolled; thus treated, a good lawn may be formed even in dry weather. In all small, open spaces surrounded by buildings, where radiation is excessive, water should be laid on, so as to be available when required, for the purpose of keeping the Grass in good condition. A very frequent source of failure in the case of lawn Grasses is defective drainage. On very large, open spaces, the Grass may be kept in good condition by grazing, for which purpose sheep are preferable to cattle.

Climbers on Walls and Fences.—These should be pruned, cleaned, nailed, and mulched. With very little care or trouble, walls and fences in towns might be made extremely pleasing to the eye during summer. Few really good evergreens are available for the purpose; one, however, which is not sufficiently used is the Euonymus; this is a most excellent subject for covering walls; it grows freely and withstands smoke. Some of the shrubby Honey-suckles may also be made available for the same purpose, especially on open fences, and when mixed with Ribes the effect is strikingly pretty. Climbing Convolvulus and Nasturtiums will also assist in beautifying unsightly structures, whilst in out-of-the-way corners Scarlet-runner Beans may be used with advantage.—E. DENNIS, Southwark Park.

Extracts from my Diary—May 12 to May 18.

FLOWERS.—Boxing tubers of Dahlias, and placing them in pits in order to start them. Sowing Mignonette in pots. Potting Caladiums, Achimenes, and Epiphyllums. Tying, stopping, and potting Schizanthuses, Mesembryanthemums, Petunias, Alyssums, and Fuchsias. Potting Camellias and Amarantuses. Propagating double Primulas. Sowing in pots seed of Dianthus Crimson Belle and Eastern Queen; also Eschscholtzia Mandarin and Sweet Pea Violet Queen. Propagating Bouvardias and double white Primulas.

FRUIT.—Pruning and nailing Fig trees on south walls; also tying Figs in houses. Thinning out and tying shoots of Melons, and fertilising all open blossoms. Putting supports to Melons swelling their fruit. Tying and stopping Cucumbers. Thinning Grapes. Sulphuring hot-water pipes in Vinery for prevention of mildew. Top-dressing Cucumbers. Thinning Muscat Grapes. Tying and stopping Vines as required, and cutting out superfluous branches of fruit. Tying Peach trees in early house. Hoeing between Strawberries; mulching them and dressing them with lime.

VEGETABLES.—Shifting Tomatoes for fruiting into cold houses. Pricking out first sown Celery into prepared frames. Potting a second batch of plants of Vegetable Marrow. Sowing another bed of Broccoli, Cauliflower, and Savoy. Hoeing between growing crops of Onions and Potatoes. Earthing up the latter where necessary. Planting out Vegetable Marrows on prepared bed, and sowing more seed under handlights on manure bed. Tying up Lettuces to blanch. Sowing crop of summer Spinach. Earthing up Peas and Potatoes. Hoeing between growing crops of Potatoes, Onions, Greens, and digging trenches for Celery. Dressing them with Amies' manure, and planting summer Lettuces on the ridges.—R. G., Burghley.

ROSES.

INSECTS HURTFUL OR USEFUL TO THE ROSE.

THE GREEN FLY. NEW RESEARCHES ON ITS HABITS.—The green fly is only too well known to horticulturists and amateurs by the destruction it commits during the whole Rose season, and every one is on the look-out for the best means of destroying it. The usual way to arrive at this result is to study the habits of the insect, to know exactly when it makes its appearance, how it multiplies itself, and how it passes the winter. The following are the results of our observations on the subject. We will first of all give a description of the female *Aphis Rosæ* :—

The body is of a delicate green in the summer, brownish-green in the winter, and about $\frac{3}{4}$ in. in length, of an ovoid form, swollen in the hinder part. Its head is black, and it has two little black eyes that are almost invisible, and a trunk or sucker formed of three pieces; a couple of black antennæ, or feelers, which fall backward over the back when the insect is at rest, but which are held upright when it walks. The thorax is black, and the three pairs of jointed legs with black joints are studded with three black spots. The longest feet are inserted at the base of the thorax, on each side of the abdomen. On the upper lateral surface there is a kind of horny process which secretes a gummy matter, which flows out in the form of transparent globules or small masses. It has, also, four wings, of which two are very small; the two others, which are twice as long as the body of the insect, are raised over the back, and are inserted in the side of the round portion which forms the thorax. It is these winged aphides that give birth to the first spring brood. They make their appearance just as Nature is awakening, and may be found crawling on the leaf-stalks and shoots of the Rose trees, where they lay, so to speak, not eggs, but living aphides. The young aphid begins to move about as soon as it is born, and generally takes refuge at first underneath its mother. The female lays about ten young ones in one place, and then takes flight to a distant part of the shoot, where it deposits another family of ten, and so on until the supply is exhausted. One female which we placed on a shoot laid six young ones in two hours, representing a production of seventy in the four-and-twenty hours. The first brood began to produce young ones in turn after their first moulting, which generally takes place in about fifteen days. This period of the aphid's life may be easily recognised by its torpor, and by its producing a quantity of floury matter with which it seems to envelope itself after oft-repeated efforts. The outer skin of the aphid then splits on the top of the head, and the insect gradually struggles out of its cast-off coat, which it leaves adhering to the leaves. It is only after the third moulting that we can recognise the females by the description given above. The wings become developed from about the seventieth to the seventy-fifth day. Before this period they may be recognised by the upper part of the thorax being provided with little transparent vesicles falling from the sides. The membranes constituting the wings are bent back on themselves, and the lower part is covered towards the head of the aphid. When once the wings have made their appearance the aphid has gone through all its transformations; it, consequently, takes flight, and distributes its progeny about the tree in families of ten or twelve. We have never yet found the eggs of the aphid on the Rose tree, but very often during mild winters, such as those of 1861 and 1869, we have seen aphides pass the whole of the cold season on the leaves which have escaped. An analogous observation was made by us in 1861, on the twigs of the Almond tree and Peach tree which were exposed to the south. We have, therefore, come to the opinion that the winged aphid drops with the leaf when it falls, passes the winter at the foot of the tree, possibly under the protection of the leaf itself, and makes its reappearance in the spring. What naturalists have hitherto taken for the eggs of the aphid are nothing more than the last brood of aphides, which assume a black, thick coat, in order to stand the winter's cold. The aphid, according to our observations, appears to be exclusively viviparous, that is to say, it brings forth its young alive without the intermediate laying of an egg. We must, therefore, watch for the appearance of the mothers of the first brood in the spring, and endeavour to destroy them by every means in our power, especially with copious fumigations of Tobacco smoke. It must be borne in mind that by killing one female in the spring we prevent the birth of many thousands of others during the year. Luckily, man has some able allies in his war of extermination against the aphides. The ordinary ant is exceedingly fond of the liquor secreted by the aphides, and they suck the insect to death in a very short time. Whenever we see even a single ant on a Rose tree we may be sure that the aphides are not far off. The larvæ of the *Hemerobius chrysops*, or lace-winged fly, also commits terrible havoc amongst the aphides, but their most terrible enemy is an almost microscopic ichneumon, which fastens on

the aphid, piercing the lower portion of its abdomen with its ovipositor, leaving an egg in the puncture. The wounded aphid at once separates itself from the rest of the flock, fixing its sucker in the skin of the shoot and remaining perfectly quiet and motionless. Its coat turns from green to pink, and from pink to bronze. It is not known how soon it dies after the attack, but about thirty days after its dead body splits open and a little ichneumon flies out, having undergone all its insect transformations inside the body of its victim, where it has not only found food, but lodging as well. In the winter of 1868-69 we made several observations on the tenacity of life shown by the aphides on the shoots of Rose trees. During the night of January 20, 1869, they resisted a cold of 14° Fahr. below freezing point. The shoots themselves were frozen, but the aphides were still alive. The old ones had preserved their usual green colour, but the young ones had become coppery in hue. This fact, amongst others, goes to prove that our winters do not exercise much effect in destroying insects generally.

DESTROYING THE ROSE APHIS.—This aphid being the most destructive of all the pests that infest the Rose, the means devised for its eradication are endless. The most efficacious, according to our own idea, is fumigation with Tobacco, which must be performed as follows: A kind of conical hood of oiled or varnished cloth is spread out on four hoops of iron wire, the lowest one being 3 ft. or 4 ft. in diameter, the three others diminishing gradually to the top. The hoops are kept together by five longitudinal rods, which are fastened together at the top of the cone, the whole of the apparatus being in the form of a sugar loaf. To the bottom hoop a cylindrical cover of the same material is fixed, the lower end of which is to be gathered round the bottom of the stem of the tree, a hole being left for the smoke to pass through. The branches of the head of the tree are drawn together and tied firmly with one or more pieces of twine. The double covering is then put over the tree and the lower part tied closely round the base of the stem. The apparatus is kept in its place by being suspended from a kind of gallows or a tripod made of three laths. Tobacco smoke is then blown through the aperture left for the purpose through a tube of about 1 ft. 8 in. long, and connected with a fumigating bellows. The tube is made of this length purposely, so that the smoke will have time to cool before it reaches the plants. If a fumigator be not at hand, we may use a flower pot half full of hot cinders, the Tobacco being slightly damped and placed on the top. The whole should be covered over with a kind of reversed funnel, the tube of which should be at least 3 ft. long and bent on itself at the end. The Rose trees should remain under the influence of the smoke for six or seven minutes. This method, which is excellent in the case of standard or half standard Roses planted in isolated positions, is, of course, inapplicable when they are planted in clumps or beds; in the latter case, use a frame or a damp cloth kept up by half-hoops, to keep it from injuring the trees. The whole being made as air-tight as possible, Tobacco smoke is introduced for ten minutes. These two methods of destroying the Rose aphid have been used by us since 1850, and success is always certain, provided the smoke is cold when allowed to come in contact with the plants. In any case, if only a few of the aphides escape destruction all our labour is lost; it is therefore necessary to drench the branches and shoots with the composition presently to be described, if this operation has not already been performed for the destruction of the Rose kermes. Every morning the stem of the Rose tree is tapped gently with a stick or cane, and the aphides drop off and fall to the ground, when they die of hunger, whilst those which endeavour to climb back to their old positions are stopped by the composition with which the branches and shoots are covered. In addition to the method of destroying the Rose aphid which we have just described, there is another to which we give the preference, on account of its being much more simple and rapid in its effects. We take a disc of sheet zinc, as shown in the annexed figure, of about 2 ft. in diameter, with a slit about 13 in. wide, extending from the outer edge to the centre, so as to allow the passage of the stem of the Rose tree. The edge of the disc is turned over a ring of iron wire about $\frac{1}{2}$ in. thick so as to strengthen it. On the underside a forked cross-piece of Pine or Oak is fixed by small nails, the two forks passing on each side of the slit, the other end forming a handle about 6 in. long, which was to hold the disc. This cross-piece with the handle should measure 2 ft. 6 in. long, and $3\frac{1}{2}$ in. wide. The disc, when required for use, is smeared over with a layer of gas-tar or marine glue with an ordinary paint brush. Taking the handle in the left hand, we hold it under the Rose tree, the stem of which passes through the slit, as shown in the figure. The stem and branches of the tree are then gently but repeatedly struck with a small stick which has been covered with pieces of cloth, so that it may not injure the bark of the tree. By this means the aphides fall on the sticky material with which the disc is covered, and from which it is impossible to escape. With this simple appliance we may clear a large number of trees from the aphid in a very short space of time. As the smaller aphides adhere to the young

shoots with great pertinacity, the operation must be repeated every few days until they have entirely disappeared. Where it is difficult to procure gas-tar or marine glue, or in cases where their use is objectionable, the following composition, which we make for our own use, may be successfully employed: Melt in a pipkin 1 lb. 4 oz. of white Burgundy pitch, stirring it with a stick or wooden spatula. When the pitch is melted, add 1 lb. of ordinary lamp oil; stir until the mixture is complete, when it may be removed from the fire. This composition always remains in a semi-liquid state, replaces the gas-tar very advantageously, and costs very little. We ought to remark that the surface of the disc should be cleaned and receive a fresh coat of the composition every time it is used.

CATERPILLARS WHICH PREY UPON THE ROSE.—These troublesome visitors belong to the Order of Lepidoptera, and are the larvae of small butterflies or moths which fly by night, and are hence called Noctue. They hide for days and days at the base of the stem or branches, and, being of a greyish-green colour, are easily confounded with the bark of the tree. We have found three families of these caterpillars preying on the Rose. The first variety is a green caterpillar

Rose Aphid Trap.

about $\frac{1}{2}$ in. in length, and 1-16th in. in diameter. Its head is green, and seems to be destitute of eyes. It is covered with a few light-coloured hairs, and has four longitudinal markings, covered by ten annular lines of a blood-red colour. It has six white transparent feet, four false feet, of which the two at the base of the abdomen serve for locomotion, as in the looping caterpillar. It hides itself in the folds of the leaves of the Rose tree, upon which it feeds. When it wishes to regain the earth it drops by a slender thread. The second variety lives on the Cabbage Rose tree. It is $\frac{3}{4}$ in. long and 1-10 in. in diameter. The body is dark green on the back, and dead white on the under side. The head is spherical, and of a yellow colour. It has two black eyes, six red legs, and seven pairs of false legs provided with suckers. The third variety is 3-5 in. long and 1-5 in. in diameter; the head is long, and of a yellow colour; the body is pearly-brown with a black band on the first ring. The nine rings are each marked with a black spot. It has six black legs and four pairs of false legs. This larva is most destructive to Hybrid Roses. It envelops the young leaves with its silky threads, hiding in their folds, where it undergoes the operation of moulting, after which it drops to the ground, when it becomes transformed into a chrysa-

lis. Specimens of three varieties were enclosed in glass bottles on May 10, and provided with food in the form of Rose leaves. From May 20 to 25 they were transformed into little oval chrysalises, which, in due course, produced a number of small moths of various colours, the general character of which was dark grey, with darker markings on the wings. To destroy these moths, we place a number of wide-mouthed, glazed, earthenware vessels, one-third filled with honey and water, at the foot of the trees. The moths, which at this time have but few flowers from which to gather food, alight on the surface of the honey and water and are drowned. On calm spring nights we may destroy great quantities of these moths by placing a lighted candle in a pan of water; the moths, being attracted by the light, falling into the water and drowning themselves.

THE RED FLY (*Tenthredo Rose*, or *Selandria excavator*.—Guerin.)—This fly belongs to the Order Hymenoptera. For many years enquiries were constantly being made as to the kind of insect whose larvae pierced the young buds of the Rose tree during spring. This fly, which we have studied attentively for the last twenty years, begins to make its appearance about the beginning of April. It measures about $\frac{1}{4}$ in. long, and about 1-25 in. in diameter. The body is black as well as the head, in which there are a couple of eyes of the same colour, and two jointed antennae, extending to the right and left from the side of the head. The thorax is black, and carries the first pair of feet, the two other pairs being inserted at the base, just where it is joined to the abdomen. The six feet are black at the end of the thighs, and white on the other portions; each leg has eight joints. The insect has four wings, the shorter ones with brown divisions. When the insect is at rest, these wings are folded together and lie along the body, which in the male is long and oval, but terminated in a point in the female. When the time for laying has arrived, the female looks out for a fitting place—on a shoot generally, at the fork of the second leaf from the top. It is here that she lays her eggs—generally a single one, rarely more. From the egg proceeds a larva, which pierces the epidermis of the young shoot and feeds on the utricular tissue. This larva is $\frac{1}{2}$ in. long and 1-15 in. in diameter. In colour it is cream-white, with a dark line extending along the back. The head is spherical in form and straw-coloured; there are also three pairs of white feet, and nine false feet on each side. During its growth the caterpillar pierces a hole in the epidermis of the shoot, after which it reaches the ground by means of a thread which it spins, and after burying itself in the earth undergoes the usual insect changes. According to our own special observations, we should advise Rose growers to endeavour to capture these flies with an ordinary butterfly net in the early morning, when they are the most easily taken, or, at any rate, in the middle of the day, when they are more shy. As for the larvae themselves, we must prune off the affected shoots, which are easily recognised by their withered appearance, taking care to burn them for fear of accident. This operation should be performed about the beginning of April, and should continue until May, at which period the bark of the shoots has become sufficiently thick to resist the attacks of these larvae, which are only apparently mischievous during the early part of the spring.

J. LACHAUME.

Pot Roses.—Where these are grown in considerable quantities in a house exclusively devoted to their culture or amongst other plants (the former is much the most satisfactory), there needs at this season to be a good deal of difference in the treatment which the plants receive according as they have flowered early or late. The principal blooming with the greater number will, as a matter of course, now be past, but those that have been kept back to produce flowers up to the time when they may be expected out-of-doors should now be put together where they can be shaded from bright sunshine. More air will be required, but it must still be given so as to avoid cold draughts, as the foliage produced under glass even now with long days and increased sunlight is much tenderer and more subject to mildew than that out-of-doors. The principal attention should be directed to the plants that have furnished flowers through the winter; those that produced bloom about the close of the year from buds set before the plants were taken indoors ought now to receive such pruning as they require, but too much should not be cut away, as, for growing in this manner, good-sized examples bear proportionately a very much greater number of flowers than small ones; the best course to follow is to cut out from the base the weakest shoots, shortening the strong ones so far, but not more than is necessary to keep the plants from getting too tall. Repot those that require it, removing all the old soil that can be got away without much disturbance of the roots, replacing it with new strong, holding loam to which should be added some sand and a liberal amount of rotten manure. Plants that do not want more root-room may have the surface soil removed and new material put in its place. It is well to examine the drainage of all, especially when there has been any worms in the pots, for where these have existed it is not usually in a satisfactory condition. Plants

treated as the above had better be kept under glass until the close of the month. Those that have flowered later, particularly the Tea varieties, must still have the protection of pits or frames, gradually inuring them to more air before they are turned out. Where room can be found, and the object is to get the plants up as strong and vigorous as possible, the Tea kinds will be found to do best wholly under glass or nearly so. Keep a sharp outlook for mildew, red spider, and aphides, and apply the proper remedies the moment any of them is observed.

Roses planted out and growing on the rafters or covering the roof of the house, especially vigorous kinds, if allowed to extend themselves freely produce in a few years wood rather than flowers. To avoid this, it will be well at whatever time the main blooming is completed to shorten back well down towards the point from which they spring about one-third of the principal shoots of which each plant consists. If this be done sufficiently early, enough strong growth will be produced from these headed-back branches to afford a sufficient and almost certain supply of flowers the ensuing year. This method will be found preferable to allowing the plants to go on for some seasons with comparatively little pruning.

Outdoor Roses.—The ungenial weather lately experienced has had a marked effect on outdoor Roses, particularly those that were pruned early; although the shoots are not killed back, the leaves have a shrivelled, seared appearance, that indicates a weakened condition of the growth unfavourable to the development of flowers, but most favourable to their greatest enemies, the Rose maggot and aphides, which always seem to thrive best when growth makes least progress. These pests should be continually sought for and destroyed, especially the maggot, for even where Roses are only required for ordinary decorative purposes, if the grubs be not killed four-fifths of the flowers will be so disfigured as to be useless. Tobacco water will be found the best remedy for aphides, particularly in the case of plants on walls, where they increase the fastest. In such situations, where the roots have often little room to extend beyond the narrow border in which they are planted without getting into a gravel path or similar ungenial medium, it generally happens that after the first few years the plants get into such a poor condition as to be ill furnished with both shoots and flowers. In positions of this kind it is seldom that anything can be done in the way of adding new soil, but I have often found it of the greatest use to thoroughly saturate the gravel path over the roots with strong manure water, given, of course, in a clear state, so that it would not affect the colour of the gravel. In order to completely saturate with the liquid in a way to fully benefit the plants, it is often necessary to dam the water up on the walk to prevent its running away until it has had time to soak down.—T. BAINES.

THE KITCHEN GARDEN.

Cutting Young Asparagus.—Two years ago a large quantity of Asparagus seed was sown here; last year, about this time, the young plants were transferred to well-prepared permanent beds, and during the season they made excellent growth. Throughout the winter the crowns were covered with manure to the depth of 2 in.; when growth recommenced this was taken off and a good sprinkling of salt thrown over the surface. Now the shoots are coming up as thick as one's finger in clusters. To leave them all would cause the stems to be quite a mass during the summer, which would be more injudicious than beneficial; therefore, we are cutting and using many of the shoots. Many assert that Asparagus should not be cut until the roots are three years old, and little until the fourth year; but this, in our case and similar instances, would simply be losing one or two years' production without reaping any advantage. The strength and quantity of the shoots should always rule the cutting more than the age of the roots.—CAMBERIAN.

Early-planted Potatoes.—It would be interesting to know how much those have gained who planted their Potatoes in March. No Potatoes could show their heads above ground during the past weeks; where, therefore, is the good of planting when at least six weeks must elapse ere it will be safe to allow the tops to appear above ground? The most ordinary observer has seen that of late years it is not safe, as a rule, to have the growths of tender plants above ground until the middle of May; and, as far as Potatoes are concerned, this can be secured by planting from the middle to the end of April. Earlier the ground is cold, and the sets and what spindly growth they make are exposed during their long existence beneath the soil to the attacks of wireworm, slugs, grubs, and rot; when planted later the sets germinate quickly, come away strongly, and escape late frosts. Planting early is with many thought to be a panacea for

the disease, but planting must, in a common sense way, be regulated by the season. I planted the bulk of my best kinds on the two last days of April, in ground ready prepared, in rows 3 ft. apart, to the extent of one-third of an acre. Those who practise early planting recommend burying the sets to a depth of 6 in. to avoid frost. What could be worse, when 4 in. is depth enough for all ordinary purposes? Sets well prepared by singling out and exposure to the light will make a growth that will forward them ten days or more when planted; therefore, if planted about the end of April, they will be through the soil in about a fortnight, and will be equal to the earlier-planted ones in less than a month.—A. D.

Potatoes Early and Late Planted.—We are always anxious to get early sorts of Potatoes planted as early as possible after the soil is in good condition, but this season the earliest planted have had a poor time of it. The ground has been so wet and cold, that in all probability late planted sets will come to maturity first; moreover, slugs, wireworm, &c., prey on the earliest planted ones, while late planted ones comparatively escape. This season has upset many practices that previous mild winters had rendered common.—J. G.

Early and Late Broccoli.—These come into use very slowly this season; even such sorts as the Penzance Early White are only just forming heads, and doubtless, when the long-expected warm weather comes, both early and late sorts will come in together.—J. G.

Compton's Surprise Potato.—I have had this Potato for several years, having obtained the tubers from a leading London house. Two years ago the leaves blackened early, and I was afraid the crop was lost, but not a large proportion of tubers were tainted. Its foliage is strikingly handsome, and it has always yielded well with me. Using it now in May, there cannot be a better table Potato.—WM. JOHNSTON, *Ballykilbeg, Co. Down.*

Slugs and the Frost.—There can be no question that slugs get out of the reach of frost however severe, for never do I remember them so numerous or destructive as they are this season; and as seedlings of all kinds are at a standstill, they have a far better chance of destroying crops than when the latter grow quickly and get out of their way. My impression is that during winter most of our garden destroyers get safely out of the reach of frost, and that after a long period of hard weather they come forth from their retreats in spring more voracious than after a mild winter.—J. G. L.

GARDEN DESTROYERS.

THE GIPSY MOTH. (HYPOGYMNA DISPAR.)

THIS handsome moth is another member of the family Bombycidae, whose caterpillars at times do a great amount of damage in orchards and among forest trees; when in great numbers they almost entirely strip the trees of their leaves. It is not a very common insect, as it is somewhat local, but where found it is often abundant. It has been given the name of dispar on account of the difference both in size and colour between the males and females. The caterpillars, owing to their voracity and size, are very mischievous, and soon ruin the foliage of any tree they may attack. Their favourite food appears to be the leaves of Oaks, Limes, Elms, and most fruit trees; but they are not very particular in this respect. The best means of getting rid of this insect is by destroying the masses of eggs, which are often $\frac{1}{2}$ in. high and 1 in. in diameter, and contain 400 or 500 eggs; they may be found without much difficulty if carefully looked for. The eggs are generally laid in August or September on the trunks or branches of trees, or on palings, walls, garden buildings, &c., and are covered by the female with yellowish hairs from the end of her body, which completely protects them from the weather. Scraping the bark of fruit trees is a good method of destroying the eggs of this and many other insects. If the pieces of bark, &c., scraped off can be collected by laying a piece of sacking, or something similar, at the foot of the tree, the operation will be much more effectual, as many eggs and chrysalides of various insects fall to the ground unharmed, and, though in an unfavourable position, may yet be reproductive. Of course, if the scraping be done in the autumn there is less danger of any eggs on the ground hatching in the spring, as the cold and wet weather of winter would probably kill them. The caterpillar can only be destroyed by hand-picking or shaking them off the branches. The latter, however, is not very easy, as the caterpillars generally shelter themselves in some crevice or sheltered place on the branches during the day, and feed only at night-time. They should be handled with much caution, as their hairs are very liable to stick into the skin of one's fingers, and cause much irritation. These hairs are no doubt a great

protection to the caterpillars, as few birds will touch them; and the parasitic ichneumons must find it more difficult to lay their eggs in caterpillars which are surrounded by such a *chevaux de frise* than in the smoother ones. The perfect insects, particularly the females, may easily be seen, on account of their light colour, resting on the stems of the trees, and as they are very inactive are easy to kill. The chrysalides may be found inclosed in very slight cocoons, in sheltered positions on the trees or somewhere near. The moths are not generally found until the end of July or the beginning of August; the females are seldom seen on the wing, but may be found on the stems and branches of trees; the males may be seen flying about in search of the females. The eggs do not hatch until the following

Caterpillar of *Hypogymna dispar*.

spring, when in April or May, according to the season, the caterpillars come forth, and at once begin to search for their necessary food. Those from the eggs laid on the trees have not far to go, but others have to make what must be to them a very considerable journey before reaching an appropriate tree. The havoc they commit among the opening buds is very great, even though their size at this season is so small. Having changed their skins several times, they attain their full size about the end of June, soon after which they select some

*Hypogymna dispar*.

sheltered position on the trees or elsewhere, and, spinning a very slight cocoon round themselves which sometimes hardly cover them, become chrysalides. The insects remain in this state for about a month. The moths measure across the open wings from $1\frac{1}{2}$ in. to 3 in.; the sexes differ considerably in size and colour as before mentioned. The males are usually much smaller and darker in colour than the females; their antennae are deeply toothed on both sides like a double comb; their general colour is a greyish dusky brown, varying considerably in intensity, with darker markings, which are sometimes hardly visible, and their bodies are comparatively slender. The general colour of the females is a greyish-white, their antennae are much less deeply toothed than those of the males, and their bodies are proportionately much stouter, and striped transversely with alternate dark and light grey bands, which are somewhat darker towards the apex; the body is terminated by a kind of brush of reddish-yellow hairs, with which the female covers her eggs as soon as they are laid. In both sexes the

upper wings are marked with three or four more or less interrupted, blackish lines, composed of a series of crescent-shaped marks, and a row of dots of the same colour on the end of the margin of the wings. The lower wings have a row of dark dots round the outer margin. The caterpillar is blackish-brown with fine wavy and reticulated markings of yellowish-grey on its body. Its head is large with fine grey markings, and with a large, triangular, yellow spot in the centre. The body consists of twelve joints, of which the first three, the sixth, seventh, eighth, ninth, and last each bear a pair of legs. On each joint are several large tubercles, which are surmounted by a tuft of stiff, reddish hairs; the tubercles on the first five joints are blue, those on the others reddish-brown. On either side of the front of the first joint are two long tubercles, each carrying a long tuft of hairs. The chrysalis is dark brown, and terminates in a long point furnished with small hooks.

G. S. S.

BUSH FRUITS IN MARKET GARDENS.

THESE consist of Gooseberries and Currants, to which may also be added Raspberries, all of which are largely grown in most of the market gardens near London in which orchards exist, for it is under the shade of such trees that the bulk of bush fruits are found. In such a position they are liable to many disasters; therefore, plants having two or three branches springing from the root are preferred, because should a limb be lost there would still be one or two remaining, whereas had there only been one stem, a fresh plant would have been needed.

GOOSEBERRIES AND CURRANTS.—These are propagated by means of pieces of the young wood collected together at pruning time and made into cuttings 1 ft. or so in length. All buds on the part intended to be inserted in the ground are removed, in order to prevent them from producing suckers that would afterwards prove troublesome. They are then placed in rows nearly close together, the rows being about 12 in. asunder, and made firm by treading the ground about their bases. Sometimes they occupy a narrow border by the side of a hedge or wall; but, generally, they are placed in open positions and intercropped with spring Lettuces. The ground in which they are to be inserted is in all cases deeply dug and well manured, and in this they quickly root and make useful sized bushes. Some raise their Currant and Gooseberry trees from layers, and in that case in the month of March whole rows of bushes may be seen layered, the branches being kept in their places by means of wooden pegs. The youngest and most supple branches are selected for this purpose; their points are cut off, a slight slit is made where the bend enters the ground, and a few inches in depth of soil are placed over the part layered. Branches thus treated soon begin to push shoots from every joint, and when these young growths attain a length of 5 in. or 6 in. some more soil is placed round their bases from the alleys. In the following October or November the layers are lifted and cut into pieces, each having two or three shoots and plenty of roots; they are then planted in nursery lines, and are allowed to remain another year, after which they are removed to permanent quarters.

In wet, low-lying districts market gardeners plant their bush fruit trees on mounds or ridges from 6 ft. to 8 ft. apart, and on the sides of these are planted Violets, Wall-flowers, Tulips, Strawberries, or any dwarf-growing crop that is benefited by a moist soil. A pathway for gathering the fruits and flowers is left between the ridges; in this way little ground is wasted, and more profitable results are obtained than would be the case were such fruits planted on the level with no other crop between them. In wet seasons small plants are much injured, so much so that some growers find a difficulty in disposing of them, except at unremunerative prices.

From Kent come the chief supplies of small fruits for preserving, and the quantities of these sent annually to London and other large towns are enormous; people, indeed, unacquainted with fruit culture on a large scale can form no conception of the vast plantations of orchard and bush fruits that are to be found in Kent. About Swanley and its neighbourhood, from any hill-top, may be seen miles of the higher-lying grounds crowned with Gooseberries, Currants, and Raspberries, and the valleys filled with Hops. In some places may be seen patches of Potatoes or Mangold, crops which are always grown on land to be afterwards devoted to fruit culture. This is done in order to get the ground thoroughly clear of Bindweed (*Convolvulus arvensis*) and other weeds, which it would be difficult, as well as expensive, to do after the fruit trees had been planted. Most people, when planting fruit trees, prefer a southern aspect; but in Kent an easterly one is always chosen—and this for two reasons: one, because the produce is always later, thus escaping, to some extent, the late frosts in spring; the other, because, should frost occur, the sun strikes the trees, gradually thawing and drying the blooms without injuring them; whereas, in a southern aspect, they are more suddenly exposed to the full force of the sun, and serious injury is often the result. It is a well-known fact, too, that crops in elevated positions escape frosts better than those in valleys. This was particularly noticeable in the case of Raspberries, which on the hills wholly escaped the severe frost of May 5, 1877 (so fatal to fruit crops in general), while in low grounds the early blooms suffered severely. Everywhere, during the fruit season, may be seen gangs of women and boys busily engaged in gathering Raspberries, Gooseberries, and Currants. Collectively, they earn large sums of money, good hands making as much as 11s. per day at Gooseberry picking, but the average rate is only about 6s. per day, and that only by means of hard work from light till dark. In Kent Currants and Gooseberries are likewise chiefly grown between orchard trees, but, in some cases, large fields are wholly devoted to them. In the latter case they are planted in rows 6 ft. apart each way, with the exception of Black Currants, which are allowed a little more room. Between the rows, until the trees get too large, a row of Peas is planted; these are chiefly early sorts, which can be picked before very dry weather is expected, and the value of the crop is of such importance that from an acre of ground is often picked 200 bushels. A woman picks in a good season 10 bushels per day, for which she is paid 3s. 4d.

The only kinds of Currants grown are the Black and Red kinds, White ones being very little in request, except for dessert. The trees are in all cases well shaped and open in the centre, and they yearly make luxuriant growth and seldom fail to bear heavy crops. The ground between the rows is kept frequently stirred by the horse hoe, and in the case of Currant bushes growing under orchard trees, of which there are hundreds of acres, many of the rows being half a mile in length, it is impossible for man and horse to work the hoe on account of the branches of the orchard trees; therefore a boy is sent to guide the hoe, and a long rope is attached to it, the end of which is encircled round a wheel placed firmly on the Grass paths that run through the plantation. To this rope a horse is yoked, and by walking straight up the path the hoe is readily drawn up the rows, the wheel, which is of course placed immediately at the end between two rows, keeping the rope in its proper place.

Gooseberries are likewise grown in a similar manner, but the greatest amount is to be seen in open fields in elevated positions. Plenty of space is allowed for the trees to expand. The branches are not shortened back to any great extent, the object being to get the trees as large as possible, and so in-

crease the amount of the crop. One very good arrangement I noticed was standard Pears and Plums placed alternately 20 ft. apart each way, the straight lines between them one way of the field being occupied by a row of Gooseberries. Between these were two other rows of Gooseberries 6 ft. apart, and between these again were rows of Strawberries. When the Gooseberry bushes are large enough they will of course require all the room, and the Strawberries will be done away with. This is, however, a very profitable method of cropping the ground, as it admits of all necessary operations being carried on without injury to either crop. Gathering commences as soon as the berries are at all saleable, and continues until they are ripe. In all cases the bushes are stripped at one picking, as much as 10 acres per week being sometimes cleared, ending with 20 to 30 in proportion as the markets require it; and as a week in favourable weather consists of only four-and-a-half days, the best market being on Saturday (to prepare for which it is necessary to leave off picking at two o'clock on Friday), the quantity of work to be done in a short time is immense; and if wet weather, which bursts the fruit, or intense heat, which scalds it, set in, picking the whole quantity is impossible. Some growers employ during the last two weeks of picking as many as 300 women and children. It only lasts a short time, and one grower told me that he sent to the north of England in two days about 300 bushels of fruit. Women sometimes pick as many as 30 sieves of Gooseberries per day, for which they receive about 10s. 6d. The chief kinds grown are Rough Reds, and a yellow kind which is generally picked when green, and also many others; the red ones are those left to ripen. A smooth green kind is likewise largely cultivated for dessert. Some growers in good seasons have been known to gather more than 3000 bushels of Gooseberries.

Gooseberries and Currants in open plantations are generally placed 6 ft. apart each way, making 1210 plants to the acre. The cost of plants if bought ranges from 8s. to 15s. per 100. Many growers (especially in the case of Black Currants) now plant an intermediate bush, which is taken out again after five or six years. By this plan they get a better return at starting. It is now found much better in Kent to form the young Black Currant into a stool instead of a bush. This is done by not taking off any of the buds when the cuttings are struck. The plant in this way forms a better head, and lasts many more years than it otherwise would do. Bush fruits are sometimes highly remunerative, often yielding from £20 to £30 per acre, and Black Currants, which have increased in demand of late years, have been known to realise as much as £60, minus the expense of marketing, gathering, &c.

RASPBERRIES.—Comparatively few Raspberries find their way into Covent Garden, owing to the large demand for them for preserving, and to immense quantities being contracted for by jam factors long before the fruit is ripe. Raspberries, however, that are sent to market are mostly gathered with their stalks attached, placed in small punnets, which are packed, some fifty together, into wooden boxes, and sent on carts to London from the neighbouring market gardens. Near London, Raspberry culture is carried on in a somewhat careless manner, the plants being principally grown between Apple or Pear trees, and the kind generally grown is the red Antwerp. The ground in which they are planted is heavily manured and trenched previous to being occupied by Raspberries. In the autumn the old canes are removed and the young ones are thinned out, so as to leave three of the best, which latter are shortened back to about 2½ ft. or 3 ft. off the ground, and they are then tied to each other at the top with pieces of tar twine to prevent them being swayed to

and fro by the wind, and also to afford greater facilities for forking over the ground between the rows, which, when done, a good coat of rotted manure is spread round the bases of the plants, in which position they remain undisturbed until the fruit is ripe, excepting that the soil during the spring is frequently hoed to clear it of weeds. Under fruit trees Raspberries succeed tolerably well, but the fruit is seldom so large or well flavoured as that produced on plants grown in open situations, and in the rich warm sandy soils of the county of Kent.

Within twenty miles of the General Post Office southwards, however, there are vast fields entirely devoted to Raspberry culture. The sort most preferred by growers in this locality is Carters' Prolific; its fruit, which is large, is of a deep red colour, a circumstance which renders it worth more money in the market than paler-fruited sorts, and, moreover, it is an abundant cropper, and the fruit ripens nearly all at one time—a great desideratum, as it always pays better to pick and sell at once than to gather at intervals. Raspberries here are planted on thoroughly cleared land heavily manured; the young plants are obtained from suckers saved from selected stools that have borne the largest crops and the finest fruit. These are cut back to two or three eyes in the autumn, and planted in rows 3 ft. apart, and 6 ft. asunder in the row. For the first three years after planting, Potatoes or Mangolds are in some cases grown between them, but after that if the Raspberries have grown well they require all the room. Three of the strongest suckers are always left for fruit bearing, and these are shortened back to about 3 ft. from the ground, the others being cut away. Late in autumn the ground between the rows is heavily manured and roughly ploughed up, a state in which it is allowed to remain until spring, when it is harrowed down, always choosing a time for the operation when the soil crumbles readily. Neither stakes nor ties of any kind are used, the canes being sufficiently strong to support themselves, and in some plantations of long standing may be found bushy-headed standards with stems about 12 in. or 18 in. high, and as thick as a broom-handle, bearing heavy crops. The ground between the rows is kept rigidly clear, both of weeds and young suckers, with the exception of such canes as are near the old stools. This work is performed by horse hoes, to which is attached a small harrow, which levels the ground and lays the uprooted weeds and suckers on the surface to be dried up by the sun.

Picking usually commences the first week in July and continues until the beginning of August. It is performed by women and children, each of whom carries two baskets of the form of a flower-pot, one in front and one behind, slung over the shoulders; these when full are emptied by boys into wood n tubs provided for the purpose—that is, if the fruit be intended for preserving, but if for Covent Garden baskets are used. As before stated, few Raspberries, however, come to Covent Garden compared with what go direct to fruit-preserving depôts—a fact which will be evident when I state that at Swanley one year a merchant informed me that he was ready to purchase 100 tons of them at £40 per ton for that purpose, although the usual price, it may be observed, is from £20 to £26 per ton. One grower, too, informed me that he had contracted with a manufacturer of preserves to supply him with 10 tons. Few of the Kentish Raspberries are picked with stalks attached to them; most of the fruit seen in Covent Garden furnished with stalks is supplied by growers near London, who pick their finest fruits for the purpose and put them at once in small punnets lined with leaves, which are then packed, in quantities in layers one over the other into large square wooden boxes or chests made expressly for the purpose.

C. W. S.

ANSWERS TO CORRESPONDENTS.

Double Narcissus.—Is the enclosed the Gold and Silver Daffodil mentioned at p. 349 of the last number of THE GARDEN?—G. H. [The flowers enclosed are those of the double white-flowered Narcissus incomparabilis of gardens, a variety popularly known as the Orange Phoenix, and perhaps the most distinct and showy of all the three double forms of the species. Of the other two double kinds, that known as Butter and Eggs has yellow perianth and orange coronal segments, and that known as Sulphur Phoenix has lemon-coloured perianth segments, and yellow coronal segments. The contrast between the white petals and rich orange and apricot lobes of the flowers set is strikingly effective. Your plant was called by Haworth *Queltia alba plena, niveo-aurantia*, but it is now, as has been stated, referred to the *N. incomparabilis* of gardens, which is a species quite distinct from the *N. double*, of which the Silver and Gold Daffodil to which you allude is a double form. The three double-flowered varieties of *N. incomparabilis* are sometimes called Lenten Roses, in allusion to their form and fragrance.—B.]

Flowerless Orchids.—Can you tell me what to do with five Orchids that utterly refuse to flower, viz., *Cattleya Mossie*, *Lelia purpurata*, *Odontoglossum crispum* and grande, and *Colozyne cristata*? The plants are kept in a small house, chiefly devoted to Begonias and Ferns, the summer temperature averaging 65° during the daytime, and in winter about 60°. The plants seem in good health, are well watered, and regularly syringed. Plants of *Dendrobium nobile* and *Cypripedium insigne* grow and flower well in the same house. Would the plants do better in a Vinery at work? I have tried every method I can hear or think of.—F. M. [No doubt your plants have been too liberally treated throughout the year. Keep them drier during autumn, and give them a lower temperature during winter, and in all probability they will flower hereafter regularly.—W. G.]

Cucumber Insects.—What is the name of the insects that I have sent? They have eaten the young growth out of a Cucumber plant.—S.C.B. [The box sent only contained one very minute beetle belonging to the Staphylinidae, a species of *Trogophleus*. I sought carefully for any other insects, but found none, although I used a lens to aid in the operation. Insects of this genus are found often in decaying vegetation, about Cucumber frames, &c., but I am not aware of their being in any way injurious to live plants; on the contrary, they are supposed to be among our insect friends, and are looking for and eating the dead and decaying vegetable. The injury done to the Cucumber plant in question must not be laid to *Trogophleus corticanus*, which is the insect sent for examination.—N. W.]

Grubs Injurious to Primroses.—The Primroses and Polyanthuses in my garden are becoming extremely injured by the enclosed grubs. Will you tell me what insect is the parent of them, so that I may endeavour to destroy them?—WINDERMERE. [The grubs are the larvæ of one or more species of *Uthyrinchius*, which are very fond of the roots and stems of Polyanthuses and other species of Primroses. *Uthyrinchius* is a *Chrysomelid*, and is a very common and dull brown in colour in many of the species, particularly in those known to be injurious to plants.—N. W.]

Wireworms.—E. A. N.—What you have sent is the perfect insect of *Elatér hemorroidalis*, the produce of one of the common and well-known wireworms. In the larvæ is very injurious to the roots of plants, and the present insect and larvæ should be destroyed wherever found.—N. W.

Double Yellow Furze.—This seems rather difficult to meet with. I shall be glad to know where it can be got in quantity, and whether it is best propagated by layering or division.—E. F. [It is most easily propagated by means of cuttings put in during the autumn.]

Greenhouse Shading.—If a "Subscriber" (p. 365) will mix whitening and butter-milk together until the mixture is about the consistency of paint, and apply it to the glass with a brush on the morning of a bright day, four months rain will not wash it off.—CAMBRIAN.

Names of Plants.—F. M.—*Dondia Epipactis*. P. I.—*Cupressus macrocarpa* (California). C. W. C.—The Narcissus sent are both garden forms, the one a rather large flower of the common double Daffodil (*N. Temonium plenus*), and the other is the Butter and Eggs *Narcissus*, a double-flowered form of *N. incomparabilis aurantiac* (*Queltia aurantiaca plena luteo-aurantia*, of Haworth).—B. E. D.—1, Form of *Begonia Rex*; 2, *Oncidium sessile*; 3, *Begonia semperflorens*; 4, *Begonia metallica*. H. Z.—1, *Rhododendron Dalhousie*; 2, *Begonia crinita*; and 3, which no collectorist variegated. P. J. N.—*Fritillaria imperialis lutea*. C. S.—*Corydalis cava albidula*, a common border flower. W. H., *Bagshot*.—Your letter contained no enclosure. W. M. C.—Send them when in flower; they cannot be named from leaves only.

Questions.

Vine Failures.—My Vines this year, after several years' success, have proved quite a failure. The sorts are Black Hamburgh, Lady Downes Sezang, and Muscat of Alexandria, the shoots of which have appeared only at short intervals, and bear a meagre description of embryo fruit. When the houses were constructed an arch was turned in the front wall, opposite the centre of each light, in communication with an outside wall, and the Vines were so planted that they were as close as possible to each arch. It occurs to me, from my gardener having accidentally found a mass of roots in the interior, that the main bulk of the roots may have turned inwards instead of passing through the arches into the border, and that the exhausted trees, which were so long in coming to the border (and had been paid), have become unproductive. I should be glad if some of your readers would inform me if my conjecture is right, and that being so, what is my remedy? Would it be advisable to take up the Vines at the fall of the leaf, and endeavour to get them quite within the border, or to cut them at the outside border, admitting the rods into the house through an aperture in the wall? or to procure fresh Vines for outside planting? Could it be possible that the solution used for the destruction of insects, which my gardener last winter applied rather strongly to the stems of the Vines, was so powerful as to have a character as to affect the vitality of the buds, though at that time in a dormant state?—E. D. T.

Cherry Failures.—I have an orchard filled with Apple, Pear, and Cherry trees, all planted four years ago last February, and they were thriving grandly up to last June, when about the latter part of the month the Cherries began to flag as if they had been blighted, or the roots chopped away. I examined the roots, but could not discover the cause. The strange phenomenon is, that the Apples and Pears by their side are doing well, and are showing plenty of bloom. Perhaps some of your contributors can kindly throw some light on the subject.—SUSSEXIAN, South.

Trees and Shrubs for Wet Ground.—Can you name any shrub or tree (besides Willow) which would thrive in a low-lying and wet field?—CAOR.

EFFECTS OF LOCAL INFLUENCES ON GARDEN CULTURE.

AN attentive perusal of "E. T.'s" remarks (p. 356) convinces me that the causes of his failure in growing even such hardy plants as Fuchsias and Chrysanthemums are to be sought for primarily in the air, and not in either the soil or the water, although these latter must necessarily, to a certain extent, be participants in the general atmospheric contamination. "E. T." only vaguely describes the situation of his estate, as being in Warwickshire, but, as he adds that it is 10 miles from any town, I imagine it is to be found somewhere in the comparatively sparsely populated centre of that county. If so, "E. T." will know better than I can tell him that to the west, north-west, and north of his flower borders and Orchid houses there runs within less than 20 miles a frontier of factories, which, from year's end to year's end, are continually vomiting forth sulphurous, chlorous, arsenical, and other noxious fumes, which, slowly but inevitably, destroy vegetable life of every description. It may seem improbable that these fumes can be carried to so great a distance, but it must be remembered that it is not only the air that plays its part in the matter, but the clouds and especially the smoke, which act as sponges, and suck up these deleterious vapours, to redistribute them in the forms of rain and smuts over many square miles of country. Mr. A. H. Church found a crystalline "message from the sea" in the form of common salt on the windows of the Agricultural College at Cirencester, the sea spray that produced it having been carried to a distance of more than 30 miles, as the crow flies, so "E. T." must not be surprised at receiving unpleasant messages from the belt of manufactories, which are to be found within two-thirds of that distance from his floral favourites. It must also be borne in mind that amounts of plant poison, which are not to be detected by the most refined chemical analysis, are quite sufficient to effect infinite mischief amongst the inhabitants of the vegetable kingdom. There being but little doubt that the air of the locality is in fault, the only remedy for "E. T.'s" failures would appear to be removal to another quarter, except, indeed, he is patient enough to wait until the action of the Noxious Vapours Acts has resulted in the purification of the air of even the Black Country. If "E. T." wishes to learn more about the action of noxious vapours on vegetation, I shall be happy to send him some articles which I wrote recently on the subject in the "Chemical News" if he will send me a post card to THE GARDEN office saying where they will reach him. It would be interesting to know whether "E. T.'s" neighbours fail or succeed in growing flowers in proportion, as they recede from or approach the Black Country.—C. W. QUIN.

The letter of "E. T." (p. 356) submits a most curious and difficult problem for solution. His case is truly a most perplexing one, and without more knowledge of all the circumstances than his letter affords, explicit as a general statement of the case though it be, I am inclined to fear he will not get really valuable help from fellow horticulturists. Less than a century ago his garden would have been set down as bewitched; he might possibly have been charged with all kinds and degrees of moral turpitude; and the aid of a priest with bell and book would probably have been invoked. Has defective ventilation anything to do with the unhealthy state of "E. T.'s" plants? It seems to me a not unlikely cause. Or have the houses been painted with any ingredient which gives off unhealthy fumes? such cases have occurred, and been unsuspected. Would "E. T." state when the condition of things he describes first began; and can he remember whether its incoming was gradual, and what class of plants was first affected? It would be well, too, to state more in detail the condition and appearance of the unhealthy plants. Are young, newly-potted plants more affected than old, well-established plants? or are both affected similarly? Is there any appearance of fungoid growth? Have the tissues been examined microscopically? and has anything abnormal been noticed? Do newly purchased plants suffer like those raised on the premises? In what way are they first affected? Has "E. T." examined the roots of the affected plants, and if so, have they any unusual appearance? Is "E. T." a dabbler in chemistry? and if so, has he analysed the soil used in potting his plants? One more query: Is it possible that any deleterious substance can have been wilfully or negligently mixed with the composts in the potting shed?—ENQUIRER.

I would recommend "E. T." (p. 356), who seeks advice on this subject, to visit some of his neighbours' gardens where the gardening is conducted under general conditions similar to his own, as there can hardly be much difference in this respect within one neighbourhood, and if he finds that they succeed fairly well in growing garden produce he may safely conclude that the fault, in his own case, is in the management; and as he confesses to having dismissed five gardeners, "all men of experience and successful growers," one after the other, before they had more than time to turn themselves round in their new situation, let alone getting acquainted with its

capabilities and peculiarities, he may safely conclude that the mismanagement in question is due to his interference. He should give his gardener a chance and means wherewith to work. If he will follow this advice, he will live, I hope, to note a decided improvement in his garden. It is paradoxical to hear "E. T." describing himself as one having an "extensive knowledge, both practical and theoretical," of plant culture, and as "an accepted authority" on horticulture among his neighbours, and in the next breath telling us that he cannot grow even the commonest plants, and has a garden smothered with bug indoors and out.—CHEF.

It is certainly singular that nothing thrives with "E. T."; it would appear that his practical and theoretical knowledge does not help him much. I should attribute the failure in question to changing the gardeners so often—five in seven years, not quite a year and a half each. What chance has a man under such circumstances to convert failure into success? Let "E. T." give a good man a fair trial for a term of years, give him a chance to master local influences, and then report results. I venture to predict that things will be different.—J. M.

PROPAGATING.

NIGHT-SCENTED STOCK.—This may be readily increased by means of cuttings made of half-ripened wood, as shown in the annexed illustration, and inserted firmly in very sandy soil. August is the best month in which to propagate these stocks, as they then make good plants for early summer decoration. Although, as I have

Cutting of Night-scented Stock.

just stated, this stock is easily propagated, it nevertheless requires care; but if placed in the shady part of a warm greenhouse without any covering it soon emits roots. When the young plants are rooted and beginning to grow, pot them off and keep them on a shelf during the dull months, ready for potting in spring, to flower in May and June.—H. H.

OBITUARY.

WE have to announce with deep regret the death of Mr. W. TILLERY, for forty years gardener at Welbeck—an event which took place on Friday, the 25th ult., aged 73. The severe winter through which we have just passed added very much to the general break-up of his health, which had been noticed by his family for nearly twelve months. He, however, attended to his duties as usual until almost the last; even ten days before his death he walked through the glass-covered wall, in which he took so much delight, and was so particular in attending to the ventilation, &c., himself. No persuasion was sufficiently strong to compel him to keep to the house during the bad, cold weather, and it was only on becoming too weak and exhausted that he took to his bed four days before his death. A man so well known and universally respected needs little to be said in his favour; we may, however, add that the gardening world has lost one of its best and brightest members, and THE GARDEN a willing and able contributor.

No. 91]

SATURDAY, MAY 17, 1879.

Vol. XV.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLOWERING SHRUBS AND TREES IN PARKS.

THAT fine old shrub, *Ribes sanguineum*, deserves all that can be said in its favour as a spring-flowering subject; had it been as difficult to grow as the Bougainvillea was at one time supposed to be, it would doubtless have been considered to be a grand plant. The double variety is very much superior to the single-flowered kind, and it also blooms later and lasts longer. It is, indeed, a fine shrub, but, curiously enough, fifty of the single-flowered sorts are planted for one of the double variety, though the latter is an equally free flowerer, and deserves the name of Burning Bush, owing to its glowing crimson colour. We think so much of it here that we have a large stock of it in pots for forcing. When the plant first became known, many years ago, it was, I believe, figured in the "Botanical Magazine" as a particularly fine shrub. The flowers are very double, and of a most intense crimson colour.

Another shrub equally good is the *Pyrus (Malus) floribunda*, which has been truly described as one of the most brilliant of spring-flowering subjects. It flowers in a young state, succeeds the Currants, lasts quite as long in bloom, and thrives in the worst exposures. These two, Paul's Scarlet Thorn, the Lilac, *Rhododendrons*, *Azaleas*, flowering Cherries, purple and yellow *Laburnums*, *Deutzia crenata* and *scabra*, *Honeysuckles*, *Spirea*, *Lindleyana* (a far hardier shrub than most people imagine), and other subjects that flower in spring and summer, should be planted far more extensively about our parks and the margins of woods than they are. All those named are hardy enough, and there is no doubt about their thriving in the north or south. The fault of park planting hitherto is the paucity of flowering shrubs, which, when they are used, are usually planted far too thinly to be effective, or they are planted in the wrong place, or under the shade of trees where they do not grow or flower freely. It is not a good plan to introduce too much of the flower garden into the park or woods. Too much dressiness in such places is objectionable, but there is certainly room for a far more extensive display of flowering shrubs and trees than there is, as from many woods near mansions they are almost entirely absent. *Rhododendrons* have been pretty extensively planted on many estates, but their display is not so far varied than they are, containing, as they do, subjects that will extend the display every season over a much longer period. It is necessary, however, that all such subjects should have room and light. They may be planted thickly at first, and with advantage in the way of shelter, but when they get crowded they should be thinned freely, and the plantations extended with those removed. No landscape gardener, as the term goes, seems yet to have grasped a conception of what might be accomplished by the free use of our large and small-flowering trees on an extensive scale, and associated judiciously with evergreen and deciduous trees of handsome outline and foliage.

A narrow line of *Rhododendrons* along each side of a Grass drive or carriage road, with tall forest trees encroaching overhead, perhaps, is but a poor attempt at this kind of decoration, when by the simple process of expansion and throwing back the lines, a tortuous track, where nothing could be seen to advantage, might be transformed into a broad vale glowing with colour and adorned with the stateliest vegetation. The broad Grass avenue at Kew, which is, or was, bordered on each side by a double row of *Deodars*, we have often thought was marred thereby, and the opportunity of carrying the idea out on broader or more natural lines thrown away. It was not necessary that such an avenue should be perfectly straight on each side, or that it should be hedged in by a fence, the purpose of which is neither to hide anything, nor to preserve anything so far as any one can see; but Kew is by no means the only example that might be adduced for the purpose of showing the fallacy of that kind of planting. J. S. W.

Hardiness of the Camellia.—This is now proved beyond a doubt. From the Isle of Wight on one hand, and Belvoir on the other, come reports to the effect that the *Camellia* has proved to be one of the hardiest of outdoor shrubs, a result quite in accordance with an observation made to me at Southampton several years ago by a lady, whose experience of the *Camellia* in the open air is large, viz., that it is harder than the *Laurel* or any of its varieties. At

the Rectory Gardens, North Stoneham, near Southampton, the residence of that centenary gardener, the Rev. Canon Beadon, huge *Camellias* have been grown for years on the garden walls, but there shelter is given during the blooming time. At Glen Eyre, which is within three miles, but is higher, not the least shelter is given, or ever has been. North Stoneham Rectory lies near the river Itchen; and it is pleaded that there the atmosphere is charged to a greater extent with moisture than at Glen Eyre, and that during the prevalence of white frosts some protection at night is necessary. Whether this plea may be correct or not, at least it is proved that on elevated places, where the soil is porous and the air fairly dry, no protection has been needed. So many thousands of good *Camellia* plants have been starved and killed in pots and tubs under glass, that its outdoor cultivation is well worth attention.—A. D.

Trees and Shrubs for Wet Ground (p. 385).—I know of nothing more profitable to grow, or that will succeed better in wet land, than the Alder. When once the plants become established, it is astonishing how quickly after being cut down they start again and yield fine poles, that is, if protected from the attacks of game, such as hares and rabbits, which are fond of nibbling the young shoots as they start into growth. Next to Alders in point of profit and suitability for wet land stands the Ash, the wood of which always meets with a quick and ready sale. Elm, too, does well where it can get plenty of moisture at the roots, and it is only when so favoured that it keeps healthy for any length of time, or acquires much size; when sound and large Elm trees are valuable. By planting the two last-named at wide intervals, the Alder will be found to do well between them, and come in as a sort of undergrowth, an arrangement by which there would not be many years to wait before the ground would yield some return. If any shrubs or plants are wanted by way of ornament, the common *Rhododendron*, *Bambusa Metake*, *Arundo Donax*, and a few plants of *Pampas Grass* might be used, and if judiciously arranged would form quite an interesting plantation. Evergreen Oaks interspersed here and there, and some of the *Coniferae*, such as the Austrian Pine, *Pinus Laricio*, and *Abies Douglasii*, would also have a good effect, but if the land be very wet, it may be necessary to plant these on raised mounds.—S. D.

Reviving Young Trees.—When young trees have been out of the ground a few days, either in transit from the nursery or otherwise, and not properly cared for, the bark becomes shrunken, and although the roots may be in tolerably good condition, there is great danger that the tree may die after it is planted. Especially is this the case with Peach trees. This may be prevented by burying the whole tree a few days. To do this, dig a trench as wide as the tree is high, and about 8 in. deep at one end and 16 in. deep at the other, and long enough to hold all the trees to be buried, when laid in the trench five or six trees on the top of one another. Lay the trees in the trench with the roots at the deep end of it, laying them straight and packing them close together, but do not pile them up above the level of the ground. Now cover the trees, tops, and roots 12 in. to 15 in. with earth. If the ground be very dry, a few buckets of water should be slowly sprinkled over the earth after the trees are buried. In four or five days they must be taken out and transplanted immediately, being careful to cut back the tops. I have known trees thus buried when taken from the pit to look as fresh as when dug at the nursery, and with proper care never knew one of them to die.—"Country Gentleman."

Magnolia conspicua.—This beautiful flowering tree which looks so well in the form of a single specimen on Grass, with its branches bending under a load of pure white blossoms, is at length unfolding its petals, and will soon be in full beauty. I look upon the time of flowering of this tree as a pretty good criterion of the general backwardness of the season, as I have on many occasions used its flowers for Easter decorations, a time when white flowers are in such great demand. This year, however, the buds scarcely showed signs of swelling at Easter; therefore this *Magnolia* is quite a month later than usual. Nevertheless, the blossoms promise to be abundant, and their lateness has saved them from getting injured by the late spring frosts that have prevailed with such persistency this spring.—J. Groom, *Linton Park, Maidstone.*

Pacific Coast Coniferae.—Messrs. Hoopes Bros. and Thomas, West Chester, Penn., say that nearly all the Pacific Coast *Coniferae* described in previous issues of their catalogue have been found unreliable for the Atlantic States; also, that they have had success in sending live plants to Mexico, Australia, the West Indies, and various European countries.

Amygdalus nana.—This has much to recommend it, as it is very early flowering and very dwarf in habit, rarely exceeding 3 ft. The colour of the flowers is deep rose, and they are produced in great profusion. For planting near the margins of shrubberies it is admirably adapted, and deserves to be better known.—W.

NOTES OF THE WEEK.

Hardy Lady's Slippers.—We have received from Mr. Douglas, of Loxford Hall, some beautiful examples of hardy *Cypripediums* grown by him in pots, including *C. acaule*, *Calceolus*, and *pubescens*. These are seldom seen in good condition in the open ground, and we did not think that they could be so well grown in pots. It is probable, as Mr. Douglas thinks, that too many stones are sometimes used in potting them. In any case we have never before seen several of the species so well grown, and hope Mr. Douglas will tell our readers how he gets such good results. *Orchis foliosa* and *Cypripedium spectabile*, both very handsome, are more easily grown. The fine yellow in the lips of *C. pubescens* and *C. Calceolus* was very fine, quite distinct from anything usually seen among stove species of the same family.

Narcissus pumilus.—Amongst notices of the Narcissi that have appeared from time to time, this little plant does not seem to meet with that recognition which its merits demand. It grows from 2 in. to 3 in. high, and, compared with its dwarfness, like *Gentiana acaulis*, it bears a very large flower. It is certainly one of the earliest and most conspicuous of spring flowers in cultivation, and, whether in lines or clumps is strikingly effective. It comes into bloom about a month before the common *Daffodil*, and “long before the swallow dares,” and if we understand rightly what Shakespeare means by “laking the winds of March with beauty,” this must be the plant; while on Narcissi what mere shadows separate some of the kinds—*moschatus* and *cernuus*, for example.—THOS. WILLIAMS, *Ormskirck*.

The Whipcord Saxifrage (*S. flagellaris*).—This Arctic rarity proves not only to be one of the most distinct of its race, but one of the freest growing. Like its near ally, *S. Hirculus*, it has large bright yellow blossoms borne, three together, on viscid stems 3 in. or 4 in. high. From each rosette slender thread-like or wire-like stamens are thrown off, which, rooting at the tips, quickly form new rosettes in mass, peaty, and gritty soil. It is one of the plants found originally, we believe, by Captain Ross during his long and dreary sojourn in Boothia, the region of the Northern Magnetic Pole. It is now blooming freely in the York Nurseries, but we understand that the stock of it is yet limited.

Orchids at Holloway.—Amongst the representatives of this popular family now in flower at Mr. Williams' nursery at Holloway is the lovely *Cattleya amethystoglossa*. Its flowers, which measure 3 in. across, are pure waxy white, copiously spotted with rich purple, and they have a bright amethyst lip. The handsome *Arhophyllum giganteum* is also finely in flower, the small, shell-like, magenta-coloured blossoms being arranged on the spikes with almost mathematical regularity. *Burlingtonia venusta*, one of the sweetest scented of any of the kinds, has transparent pure white blossoms, which are smaller than those of *B. fragrans*, and produced in gracefully-drooping, dense racemes. *Dendrobium superbiens* will also shortly be finely in flower.

Strawberries in Pots.—We have received from Mr. Muir, gardener to C. R. M. Talbot, Esq., M.P., Margam Park, Glamorganshire, samples of fruit of the Vicomtesse d'Hericart de Thury Strawberry, gathered from plants in 3-in. pots. They were lifted from the ground and potted into them about the beginning of last September. Until the beginning of March, they had stood out all winter quite unprotected, frozen hard nearly all the time, and looking more dead than alive. Being in such small pots, and thinking they were useless, no attention was paid to them until March, when they were taken in hand, and the result is that each plant has produced about a dozen large, richly-coloured fruits. It should be added that ever since the latter have been formed they have been frequently watered with Amies' manure in a liquid state.

Hardy Flowers at Tottenham.—Though here, as elsewhere, owing to the lateness of the season, there is a comparative dearth of blossom, yet we noticed the other day many rare and interesting plants, such as the Virginian Liverwort (*Mertensia virginica*), a plant which delights in a boggy peat soil. It grows about 1 ft. high, has oval, stalkless leaves, and dense, terminal, drooping clusters of blossoms, which are each 3 in. long, funnel shaped, and bluish-purple, changing to a lighter hue. Another elegant North American plant is the Anemone-like *Thalictrum* (*T. anemonoides*) a plant 6 in. high, with small, Maiden-hair, like foliage, and slender stems terminated by several pure white blossoms, nearly 1 in. in diameter. When planted in masses it is extremely effective, and ought to be oftener met with than it is. The white variety of the charming *Anemone apennina* forms a fine contrast to the pleasing soft tint of the type. The same may be said of the white-flowered form of the spring *Adonis* (*A. vernalis*), which is also finely in flower. A variety of the common *Iris pumila*, named *pallida*, is very pretty, as the flowers

assume a deep sky-blue tint; and make a brilliant display in masses. The Caucasian *Iris* (*Xiphion caucasicum*), though not very showy, is a very distinct kind, with pale yellow blossoms and Grass-like foliage. The North American *Trillium* are now in full beauty, the best of all them being *T. grandiflorum*, a plant seen to best advantage, as it is here in large masses. *T. sessile* is a quaint-looking kind, with mottled foliage and erect, stalkless blossoms of a deep red colour. *T. erectum*, a dwarfier kind than the last, also with blood-red flowers, is in full bloom. The true *Scilla amena* may here be seen in perfection; it is from 4 in. to 6 in. high, and has stout, reddish-coloured flower-stems bearing deep violet-blue blossoms nearly 1 in. across. *Ranunculus aleximilex* is one of the best of the *Crowfoots*, and a very pretty effect it has when seen in clumps; its pure white, golden-eyed blossoms keep up a continuous display for a considerable time. *Polemonium Richardsoni*, a very distinct North American plant, is excellent in borders, as it flowers so freely, and the deep lavender tint of the blossoms is so very pleasing. *Fritillaria recurva*, undoubtedly the finest of all the *Fritillarias*, is also beautifully in flower in this nursery. It is fully exposed, though, as a precaution, the protection of a frame light was given it during the late severe winter. Its flower-stalks, which are about 6 in. high, bear terminal clusters of drooping, bell-shaped flowers, 1 in. long, of a beautiful scarlet and orange colour.—G.

Senecio concolor.—This new greenhouse perennial, lately introduced from South Africa by Mr. Bull, has much to recommend it, and doubtless it will, when better known, prove a highly decorative and useful plant. It has a tuft of lance-shaped root-leaves, which are deeply cut and covered with a hoary substance. The flower-stems, which rise from 12 in. to 18 in. high, are produced plentifully from the base of the tuft, at first horizontally and afterwards erect; the stems, which are branching, bear star-like flower-heads, 2½ in. in diameter, of a bright violet colour, and they last a considerable period in perfection.—G.

Ornamental-leaved Broccoli.—We have received from Messrs. André Leroy & Co., Angers, leaves of a curled proliferous Broccoli, which during the whole winter has produced a most striking effect, and which has been admired by every one who has seen it. Some of the leaves are red and some variegated in an interesting manner, and the coldest weather suits them the best.

Odontoglossum vexillarium.—The show of this Orchid in the York Nurseries promises this season to eclipse that of any previous year. Already the display is magnificent, and a little short of 1000 flowers will be in bloom during the next few weeks. Whether from the lower winter temperature, or the more protracted coolness of the spring, we do not know but the blossoms are certainly finer than those of last year both in colour and size. They vary from deep rose, through every shade, almost to white. Scarcely can two be found alike, and the irregular blending of the various shades gives a general effect of colour which is indescribably beautiful.

Narcissi Emperor and Empress.—Never, perhaps, was a grander sight seen amongst bulbous plants in any garden than the display of these two noble hybrid *Daffodils* in the York Nurseries at the present time. Whole beds, with thousands of flowers of enormous size, present a mass of bloom of extraordinary beauty. The Emperor is the largest *Daffodil* in cultivation; and the Empress, though scarcely so large, has the advantage of nearly white petals, which contrast finely with the deep yellow well-dilated tube.

Cattleya Skinneri alba.—Fine-flowering examples of this rarity may now be seen in Mr. Bull's nursery at Chelsea. It differs from the type only in having blossoms of waxy whiteness, with nothing to mar their purity except a faint dash of lemon tint inside the lip, and delicate pencillings of purple at its extreme inner base. It has also the same free-flowering tendency as *C. Skinneri*, bearing from six to ten blossoms on each stem.—W.

Griffinia Blumenavia.—This beautiful bulbous plant is a decided acquisition to our list of stove plants. In the state in which we saw it in Messrs. E. G. Henderson's nursery, Maido Vale, it is somewhat dwarf in habit, with lance-shaped leaves and short, stout flower-stems terminated by an umbel consisting of numerous blossoms, which are 2½ in. long, 1½ in. across, white, beautifully mottled and veined with purplish-pink. Like all the species, it is a native of Brazil.

Retirement of Mr. Marnock.—After over forty years' practice as a landscape gardener, Mr. Marnock has retired. All who know him will unite with us in regretting that the most successful of English landscape gardeners should cease active work in the creation of such gracefully laid-out gardens as those made by him in many parts of the country. Mr. Marnock has made arrangements with Mr. J. F. Meston to succeed to his practice, Mr. Meston having been long associated with Mr. Marnock and other landscape gardeners in their work.

The Rose Show of the Royal Horticultural Society, which was announced to be held on June 24, has, owing to the lateness of the season, been postponed to July 8. Mr. Wm. Paul and Mr. Charles Turner intend having special exhibitions in connection with the show, and a display of Roses of unusual magnitude is anticipated. The Pelargonium Society's Show is also postponed, and will be held at South Kensington in conjunction with the Rose show.

Calochortus lilacinus.—This beautiful and rare bulbous plant we noticed in flower a few days since at Mr. Joad's garden, Wimbledon Park. In colour and form it is similar to *C. splendens*, but is smaller in all its parts. It is very free flowering, and the delicate lilac tint of its blossoms is very attractive. It is synonymous with the plant figured in the "Botanical Magazine" (t. 5804) as *C. uniflorus*, but which is a distinct species. It is also known as *C. umbellatus*.—W. G.

Anthurium Scherzerianum at Chelsea.—Numerous specimens of this gorgeous stove plant are now in full beauty at Messrs. Veitch & Sons' nursery, and form a very brilliant spectacle. Amongst them are several varieties differing in brightness of colour and size, which varies from the immense spathes of Ward's variety to the small-sized ones borne by the originally introduced plant, thus plainly illustrating the good results achieved by skilful cultivation. The form with two unequal spathes is very interesting, and the white-spated form is also very desirable for the sake of variety.

Muscari paradoxum.—This new Muscari is so distinct from any other cultivated kind, that it is especially noteworthy. It grows about 1 ft. high, with three erect leaves, nearly 1 in. wide, and deeply channelled. The flower-stem, which is stout and from 6 in. to 9 in. high, is terminated by a conical raceme of densely arranged oblong flowers, of a blue-black tint, faintly perfumed. It is a native of the Caucasus, whence it was sent a year or two since by Dr. Regel, of St. Petersburg, to the Kew collection, where it is now in fine flowering condition.—W. G.

The Double-flowered Caltha (*C. palustris* fl. pl.).—One of the brightest ornaments among hardy plants at this season is this handsome marsh plant. Its numerous compact golden heads of blossoms are very effective, rising above the rich deep green of the foliage. In the bog garden or other moist places, or even in the ordinary border, it thrives admirably, and is decidedly superior to the single-flowered ordinary kind.

Dendrobium luteiflorum var. Freemani.—An importation of this fine variety of *D. luteiflorum* was offered for sale the other day at Stevens'. Amongst the plants thus offered some were in flower, and afforded ample proof of the high merits of this variety. We hear that the remainder of Mr. Freeman's importation has been entrusted to Mr. Howard, of Southgate, for disposal.

Erysimum pumilum.—One of the prettiest of Alpine gems at this season is this pigmy Crucifer, which now enlivens the rocky borders at Kew. Its height is not more than 2 in. It has a spreading habit, and is studded thickly with clear yellow blossoms, which are rather large for the size of the plant. As it is so easily grown, and may be freely propagated by means of seeds, &c., it should adorn every rockery or select border.

Veronica Hulseana.—Too much can scarcely be said in praise of this beautiful New Zealand Speedwell as a greenhouse plant. It grows from 1 ft. to 2 ft. high, and produces delicate lavender-tinted blossoms in great profusion in the shape of long, terminal, branching racemes. As a pot plant or for planting out in sheltered positions during summer it is highly desirable, and certainly deserves to be better known than it is.—W. G.

Waterer's Rhododendron Exhibition.—Mr. John Waterer's show of Rhododendrons—always one of the most interesting of London floral exhibitions—will be held during June next, in the gardens of Cadogan Place, Sloane Street. A large tent has already been erected there for the reception of the plants.

Cattleya Alexandræ.—This is the name of a very beautiful variety of the *C. Mossia* type, which we saw lately in Mr. Bull's nursery at Chelsea. The blossoms, which are pure white, have a delicate blotch of a magenta tint on the elegantly crisped lip.

Tulipa Kolkowskyana.—This new hardy plant may now be seen in flower at Kew. Its general aspect at once reminds one of our indigenous species *T. sylvestris*, as it grows to about the same height, and the flowers, which have narrow yellow segments, are about the same size. Probably when it becomes more fully developed it will present a more distinct character and make a pretty border flower.

DR. ISAAC BALFOUR, of Edinburgh, has been appointed to the chair of Botany in Glasgow University.

Gentiana verna.—In the nursery of Messrs. E. G. Henderson and Sons, St. John's Wood, a large number of this, one of the loveliest gems of the European Alps, grown in pots and flowering abundantly, is now a sight worth seeing, as it is a sheet of the deepest sky-blue. It also affords sufficient proof that it may be successfully grown in pots, provided there is no lack of moisture during summer.

Hose-in-Hose Polyanthus.—We have received from Mr. Dean, Bedford, near Hounslow, some charming examples of these interesting spring flowers. When seen in masses, the double corolla gives a depth of colour which similar masses of the single kinds do not possess.

Camellias in Kent.—Mr. Marnock has sent us some beautiful blooms from Camellias growing in the open air in his garden near Tunbridge Wells. They are as large and fine as blooms cut from plants indoors, and the foliage even more robust and glossy.

THE FLOWER GARDEN.

The Two-spiked Aponogeton (*A. distachyon*).—One of the most interesting sights in open-air gardens at this season of the year is a tank or lake studded profusely with the pure white blossoms of this plant floating upon a mass of emerald green foliage;

The Cape Pondweed in an English Ditch.

its chaste beauty, too, is much enhanced by the delicious Hawthorn-like perfume which pervades the atmosphere wherever this aquatic grows. Such a sight may now be seen in Mr. Parker's nursery at Tooting, where myriads of its blossoms are just in perfection, and have been so for some time past. As to its hardiness, there can now be no doubt, as the plants in question have not received the slightest protection during the severe winter which we have just passed. It evidently thrives best in a running stream, but it may be grown successfully even in a tank of stagnant water, provided it be replenished frequently. For growing in indoor aquaria it is no less desirable, as it flowers very freely, but in that case one plant alone will be sufficient, as the scent of the blossoms from more than one would be overpowering. We noticed the other day, in Mr. Ware's nursery at Tottenham, several flowers with a decided bluish tint, which, if permanent, will render the variety a charming acquisition for association with the type.—W. G.

HARDY OUT-DOOR PLANTS.

DURING the last six days we have had a low temperature, and three nights from 2° to 4° of frost, still we have a fair show of flowers in pots (plunged outside), and on rockeries *Androsace villosa*, *A. carnea*, and *A. Vitaliana* are in bloom. The walls are enlivened by the new growths of variegated Ives and *Jasminum nudiflorum*. A large yellow Pansy, 2 in. across, has kept us company all the winter through, when the snow did not cover it; and the same may be said of those fine varieties of Daisies, Sweep and Bride. It is worthy of mention, that some Hyacinths grown in pots, and forced in February and March, 1877, were put in at the base of a small rockery having a south aspect; last spring they only made strong healthy foliage, but now they are finely in bloom. *Aubrietas* are just now beautiful, and *Gentiana acaulis* is better than we have had it before; perhaps because I had it all moved to the dampest positions on rockeries which I could find. With some of the finest double white and sulphur Primroses before me, I feel at a loss to know why they are not oftener seen than they are in gardens. They

are faithful to us under all circumstances, and what can be finer than patches of common Primrose, 4 ft. in diameter, under the yet bare trees. Hardy Fuchsias (so called) and some of the ornamental Grasses are killed wholesale: *Aralia Sieboldi* and its variegated kind have stood, losing only some foliage; the same may be said of Sweet Bay. Common Laurel, Laurustinus, and Fire-thorn have suffered very much, but are now reviving. The new round-leaved Laurel has stood the winter much better than the common one even in a worse position. Several varieties of Hydrangea have also braved it well, the kind with nearly all white foliage included. Tulips not taken up for two seasons are grand. *Primula cortusoides* and *P. c. amena alba* are full of blooms yet to open. I had six varieties of the shrubby Veronicas, and all but one are gone; I fear I have also lost *Ramondia pyrenaica*, *Oxalis rosea*, *Achillea Clavenna*, *Papaver croceum*, *Lippia nodiflora*, and *Anthyllis Vulneraria*. *Solanums* are cut to the ground; *Aucubas* and *Hollies* never looked better and are full of bloom. Just now *Epimeediums*, *Daphne Cneorum*, and *Corydalis bulbosa* are cheerful subjects. *Arabis rosea* shows in grand contrast with the white-flowered kinds. *Orchises* are yet out of sight; these, I fear, are too dry and too much exposed to the sun on our south rockery; they did not look healthy all last summer. *Meconopsis nepalensis* has suffered very much; I hope that it is not now being finished off by the powerful mid-day sunshine. *Catalpas* have all suffered severely, but, reverting to our little favourites, I have a treat in *Adonis nivalis* and *Alpine Auriculas*, the latter raised from seed sown more than a year ago. Many blooms are larger than half-crowns, and the colours are superb. I grow them in frames, which, I believe, have never been entirely closed throughout the winter.

J. WOOD.

Woodville, Kirkcaldy.

SPRING FLOWER GARDENING.

SELDOM has a season more adverse as regards a display of spring flowers been experienced than the present; and where summer gardening has to be carried on in the same beds many of the ordinary earliest flowering plants will scarcely have reached their full bloom before they must be cleared off to make room for their successors. This part of Kent is generally considered to possess a mild climate, and early flowers would certainly be as forward here as in most parts of the kingdom; yet I must confess that, as far as spring flowers are concerned, the majority of them are a failure. The only ones that have been really satisfactory are those which have been planted in sheltered beds, banks, or borders, where the friendly shelter of overhanging branches has mitigated the force of frost and wind. We have had as fine a display of *Aconites*, *Snowdrops*, *Primroses*, *Dafoids*, and similar flowers as any one could desire, where they are naturalised in masses principally under trees where the turf is thin, and where little mowing is needed; but as regards the same class of plants in open freshly-dug beds, they have been so late and so weatherbeaten as to be scarcely presentable at any time. Under such uncertain conditions of climate, our future attempts at winter and spring bedding must eventually, I think, come to be confined to fine foliaged plants more than flowers, for, beautiful as beds of Forget-me-not now are, they are scarcely more attractive during winter than masses of bare earth. But when a good selection of dwarf shrubs, or trees in a young state, such as many of the Conifers are contrasted as to colour, habit, &c., and the soil is carpeted with spring flowers, a pleasing effect is produced the whole season through. There is no need for experimenting with half-hardy plants, as the best shrubs for the purpose, viz., *Retinosporas*, *Cypresses*, *Aucubas*, *Berberis*, &c., areas hardy as any plants which we possess, and the flowering plants which we employ should only consist of those that are in full bloom before May, even in the latest seasons, otherwise they should be placed in the field of early summer flowers. For this reason bulbs, such as *Crocuses*, early Tulips, and *Hyacinths*, should be freely planted, and the earliest varieties of *Pansies*, *Arabis*, *Aubrietias*, and similar trustworthy early-flowering plants that give a bright look to the beds early in the season should only be deemed admissible for the spring flower garden. Of course in any mixed arrangement that has not to be cleared off at a given time, a much larger variety of plants would be eligible, as when the mode of arrangement allows of a gradual blending of the seasons by moving any plant that has completed its allotted time and replacing it by one coming into bloom simultaneously, and when, in a season like the present, the flowering of spring plants comes on the heels of those of early summer, a blank is made that upsets the whole effect. We cannot alter the seasons or the effect which they have on vegetation; therefore the wisest course would be to prepare beforehand for severe winters by only planting frost-proof subjects, the variety of which available is sufficient to satisfy the most extensive wants that are likely to arise.

Linton.

J. GROOM.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Bedding Violas.—I regret to find that the few remarks which I made (p. 369) upon these beautiful spring and summer-bedding plants should have called forth such a discordant note as that which has emanated from "Cambrian." I gave my experience of these Violas here in the south; he, his knowledge of them under circumstances very dissimilar, and it is unfair to assume that, because certain kinds may not be good in his locality, they are not good elsewhere. At the Chiswick trial of Violas, conducted for three years in succession, Yellow Boy proved to be the earliest of all the yellow kinds, beating all the northern varieties which were there. Of the two kinds named, *Ilacina* and *rubra Ilacina*, both of which "Cambrian" deprecates, I find that both were awarded first-class certificates at Chiswick, where they were exceedingly beautiful, and they are the same here every summer; both furnish hues of colour produced by no other Violas. The *Tory* mentioned by "Cambrian" does not class with the purple self kinds to which *Cliveden Purple* and *Mulberry* belong; it is of a bluish-purple hue, and is very good in its way, but it is not one of the so-called purple section; nor is it blue, and in this respect it compares badly with *Blue Bell*, *Blue King*, *Blue Beard*, and others. *Holyrood* is a large, massive flower, of an indigo-blue hue, and is better suited for classing with show self *Pansies* than with bedding kinds, at least, such is its character here. The most popular and most widely-grown Viola is *Blue Bell*, and for constancy it has never been excelled. I send a few blooms of the kinds just named, including the *Tory* and a beautiful yellow self, quite new, named *Queen of Spring*, sent out by Mr. Vertigans, of Birmingham.—A. DEAN. [The blooms received from Mr. Dean were clear and decided in colour and very beautiful. The blues and purples fully confirmed all he has stated respecting them, and nothing could possibly be brighter or more charming than some of the yellows or better as regards substance.]

Wallflowers in Market Gardens.—We have had two bad winters in succession for the blood-red Wallflower so largely grown for market use. Last year late spring frosts so crippled the plants that they died wholesale, and the worst crop of seed on record was the result; where pounds were looked for half ounces only were obtained, and, as a consequence, the price has gone up enormously. A large grower here saved enough last summer, and only just enough for his own sowing this spring. Early sowing on generally a fine day in January is the rule, and it has followed that the seed either did not germinate, or that the plants have disappeared under the combined effects of cold and vermin. This cultivator and his neighbours had hitherto sold and bought seed from each other at about 6s. per lb., but none had any to spare. He therefore applied to other seedsmen for seed of a good stock, and was informed that he would be charged 2s. 6d. per oz., or at the rate of 40s. per lb., and so scarce are good strains that this is now but a fair price. This spring, in addition to the difficulty in raising seeds, the grower finds that large numbers of the plants have been killed, old or very early-planted ones wholesale, and that the market for the flowers, owing to their having burst out all at once, is a dull one. Looking to the high price of seed, and the low prices commanded by the flowers, larger breadths will be saved for seed this year, and therefore next spring the price may be about an average one. I observe that in one or two gardens considerable breadths of the new rose-purple kind of Continental origin are being grown, and that they look exceedingly effective, but whether they will fetch good prices or not remains to be seen. Market folks are eminently conservative in their likings, and it is exceedingly difficult to get any good new plant into a remunerative sale.—A. D.

Crown Imperials.—Permit me to thank "H. P." (p. 369) for his kind invitation. I hope to see him some day, and am anticipating much pleasure and profit from the interview. But he has mistaken the object I had in view; I had no thought of self-glorification, and the allusion to the number of flowers and the height of the stems, was merely to show how beautiful *Crown Imperials* are with only ordinary border treatment; indeed, I found, on looking closer at the groups, that I had understated both their height and the number of flowers which they bore. But my sole motive was to recommend their culture, as I find, from questions frequently asked, that scarcely one person in a dozen even knows what they are; and yet there are but few plants when in flower that produce a greater impression upon all who see them.—E. HOBDAY.

Hardy Japan Primulas.—I observe that Mr. Douglas discourages the planting of the varieties of *Primula amena* in the open ground, as the flowers and leaves are fragile and liable to be injured by winds. It is worthy of note, however, that these plants are perfectly hardy, a quantity here of various kinds having been exposed in pots all the winter without protection of any kind, and not one has been injured, although in some cases the pots were split all to

pieces. As to suitability for planting out, it is also worthy of remark that when planted out they produce leaves and flowers much later than when grown under glass; the flower-stems are shorter and stouter, and the plant accommodates itself better to its position than it would do under different circumstances. Planted in sheltered spots and in nooks on rockwork, clumps of these *Primulas* would prove extremely beautiful during the month of May.—A. D.

Hardiness of the Variegated New Zealand Flax.—Amongst cultivated plants we from time to time meet with exceptional instances in individuals that on account of their hardiness, or other properties, stand in direct opposition to our preconceived opinions formed upon data generally reliable. Variegation, be it disease in the strict sense of the term, as some maintain, or otherwise as held by those who point to the continued vitality exhibited by many of the longest known examples existent amongst cultivated subjects in this state, is still usually found to bear with it a weakened condition of the plant so affected that shows itself in some way or other, often through less endurance of the leaves proportionate with the more or less absence of green colour present. The plant under notice (*Phormium tenax*) in its normal and variegated state has this winter stood out of doors in many places, and has afforded conclusive evidence that in its case variegation is not accompanied with an enfeebled condition; for, in every instance of which I have heard, the variegated form has withstood the winter better than the green one. It is gratifying to learn that this stately plant in any form can, with slight protection, be enabled to bear a hard winter, if only in the more southern parts of the kingdom. And the fact of its being hardier in the variegated than in the green state opens up further ground for considering the interesting subject of variegation in general.—T. BAINES.

New Allium.—A very handsome addition to our list of hardy bulbous plants is *A. Erdeli*, figured in the current issue of the "Botanical Magazine" (t. 6426). It is dwarf in habit, being not more than 9 in. high when fully grown. The leaves are broad and glaucous, and produced in a rosette on the surface of the ground. The flower-stem, which is stout, is terminated by a dense head of blossom, about 1 in. across, toothed at the edges, and pure white in colour, which contrasts admirably with the bright claret-purple tint of the centre and pale yellow anthers. It is a native of Palestine, extending along the Lebanon range to Jerusalem. It is perfectly hardy and of the easiest culture. It may be propagated by means of numerous small bulbils which detach themselves annually from the mature bulbs.—W. G.

Chrysanthemums.—To grow these really well in borders, they should never stand longer than a year without being renewed or replanted, and instead of a large number of stems being allowed to start up together, they should be limited to three or four at most. Being naturally of a gross-feeding nature, it is necessary that the ground where they are to be planted be deeply trenched.—G.

RANUNCULUS LYALLI.

At last this long-heard-of plant, known as the "Water Lily of the Shepherds, of New Zealand," has flowered and been exhibited for the first time in Europe, the honour of doing which belongs to Messrs. Veitch, who exhibited it in a flowering state at the Royal Horticultural Society's meeting on Tuesday last, having successfully

imported it in quantity through Mr. Peter Veitch, to whom our collections are indebted for so many rare and beautiful acquisitions. As a species, it is allied to the very few which are characterised by their shield-like leaves of leathery texture and by erect stems, the blossoms being white or cream-coloured. The Chelsea specimens are necessarily in an immature state of development, and in their present condition they considerably resemble *Nelumbium speciosum* in miniature, except that the flowers are of the purest white, with a central tuft of golden-yellow stamens, which much enhance their chaste beauty. Its native habitat is in moist places in the Southern Alps of the Middle Island, where it is said to attain a great size, the leaves measuring 15 in. in diameter, and the flowers 4 in. across. As it is found at considerable elevations, we may presume it is quite hardy in our climate, and now that such satisfactory success has attended its culture, after so many repeated attempts at various times to grow it, we hope that such a desirable acquisition will never hereafter be lost to our gardens.

W. G.

Hellebores in Pots.—Although these will grow almost anywhere, or in any soil and situation, nothing pays better for a little care and attention at starting; and the plants are of such an exceedingly useful character as to be quite deserving whatever labour may be expended on them, for it may truly be said of the Christmas Rose when well grown, that you may "cut and come again," and the flowers are of that lasting, enduring nature as to be almost unrivalled by any other. Their value, as pot plants for window or greenhouse decoration, is scarcely second to any at the season they come in; this is a purpose for which they are deserving a much more extended cultivation than they now receive, as they may be

lifted from the ground towards the end of November, and placed away anywhere in a cold frame till they get into bloom. For patches to stand permanently there is no better place than the margins of Rhododendron beds, as there the soil is of that description as to suit their wants, and they can remain without disturbance, and be much better circumstanced than they would be in mixed beds or borders. Till I obtained a few plants of *H. niger maximus*, I was under the impression that the Christmas Rose was a slow plant to propagate; but I have not found it so with that variety, as in the space of a little over a year I have got quite a stock, and this might now be considerably increased. I note that numbers of seedlings have been raised, but as yet I have been unable to get a single pod, although I have tried artificial fertilisation.—D.

The "Water Lily of the New Zealand Shepherds" (*Ranunculus Lyalli*).
As exhibited by Messrs. Veitch & Sons at South Kensington on the 15th inst.

THE KITCHEN GARDEN.

Spring Crops and Slugs.—The present spring has proved that hard winters are not destructive to slugs. Our land is as badly infested with them as it was last season, and some hundreds of young Lettuce plants have been sacrificed by them this spring. The best remedy we have tried for protecting seeds from slugs is sawdust; nothing baffles them like this laid on the beds about 1 in. thick; no slug will pass over it, and it is nearly equal to Cocoa-fibre as regards warmth and conservative power. With the bitter experience of the present spring, it behoves all who have frames at their command to make free use of them for sowing and forwarding all kinds of vegetable crops that will bear transplanting; by doing so we have, at the present time, thousands of strong plants nearly fit for going into their permanent quarters.—J. ROBERTS, *Gunnersbury*.

The Broccoli Crop.—Broccoli heads this year are small, and, as a consequence, plants that have been so far spared by the severe winter will produce but a poor crop. Market growers who were persuading themselves that at least they would have some good Broccoli to send to market are now discovering that the heads are mere buttons, and, in cutting, find that the centre or pith of the stems is blackened and destroyed. This is inevitable; when hard winters prevail, and it serves to illustrate the vicissitudes to which market gardening is subject. The early spring was full of hope, but this the past two months have blighted. Nothing grows, and seedlings are fast vanishing from sight.—A. D.

Dry Fern and Straw for Protecting.—During the past winter the weather has been of such a character, as to prove what is the best materials for protecting purposes. Early in December last I covered some rows of Celery; half of them was covered with dry Fern, and half with dry, long litter fresh from the stable, and when we came to dig the Celery, that which was protected with Fern had scarcely a bad stick, while that which was protected by Straw was two parts out of three rotten, all being side by side planted at the same time and the same sort, namely, Sulham Prize Pink. This I find to be a good Celery.—J. C.

Orange Jelly Turnips.—The past winter has tried Turnips as well as other things, especially those that were sown late to stand through the winter for use in spring. I sowed three sorts, Early Six Weeks, Snowball, and Orange Jelly; the last has proved much the hardiest. While the two first got cut badly and many rotted, this stood uninjured, although sown side by side and at the same time. Some do not like it because of its yellow look when cooked, but that is no detriment. I would recommend all who have not grown it to give it a trial.—J. C., *Farnborough*.

The Witloof.—This is not a new vegetable, but although extremely common in many parts of the Continent it is scarcely known in this country; it is a plant of the easiest cultivation. Sow in rows 1 ft. apart, about the middle of this month, not earlier, as it is very apt to run to seed; thin out the plants to 8 in. apart in the rows, keep the ground well hoed and clean throughout the growing season; between the rows give at stated intervals good soakings of liquid manure. When the plant is in vigorous growth take up a few when required, cutting off the green tops. As winter approaches, place three to six roots in a large pot, filling it up with mould, and with a smaller sized pot cover it up closely to prevent light from getting in, and place the pot in heat, or in a warm cellar. In about three weeks it will have produced five tender-leaved heads of a pale yellow colour, equally good to be eaten as a salad or boiled.—B.

EFFECTS OF THE WINTER IN ANTRIM.

I HAVE read with interest "O.'s" account (p. 370) of the effects of the winter in the south-east of Ireland; perhaps I may be permitted to add a little from the north-west. Contrary to "O." we have here for the most part a soil inclined to be heavy, and almost wholly resting on limestone, of which there are extensive quarries close to us. Like others, we have lost many plants on walls; the blue Passion-flower (*Passiflora cerulea*) on southern and other aspects is entirely killed. *Escallonia macrantha*, *Lycæstera formosa*, and *Magnolia grandiflora* are killed to the ground, but will mostly push again from the bottom. Three years ago I planted out in a sheltered nook a good sized plant of the *Magnolia* from a pot; it grew well until last winter, when it succumbed. Shrubby Veronicas, Sweet Bays, *Laurustinus*, White Broom, a hedge of *Berberis Darwini*, large clumps of Pampas Grass and *Tritoma* Uvaria, are all killed outright, except the last-named, which may push again from the roots. Many branches of the common Laurel are killed, especially where they formed an arbour over walks; no doubt the result of cold draughts. *Wellingtonias*, *Taxodiums*, and others are badly hurt. In

mixed borders all *Antirrhinums*, Stocks, and most of the Wallflowers are gone; of the latter Belvoir Castle has stood the best. Beds of *Primula japonica* (with some I have heard not quite hardy) have stood here with impunity, and are now showing flower strongly. The kitchen garden suffered severely. Broccoli, consisting of such hardy sorts as *Alexandra*, *Cattell's Eclipse*, &c., Savoy, Winter Greens, Parsley, and Sage, were killed; the only vegetable which survived here was Brussels Sprouts. All through the spring the weather has been of the most adverse character, and, I fear, will prove injurious to tender wall fruit. We have had an excellent bloom on Peaches and Nectarines here on south walls, but, unfortunately, at that time, we had nightly 10° and 12° of frost, and now Plums, Cherries, and Pears on warm walls are as white as snow, the two former past their best as regards blossom. It will be the end of the month and into June ere standards of the same and Apples will expand their blossoms. S. K.

Templepatrick.

Shelter for Fruit Trees.—This is a subject that deserves serious consideration from all who contemplate forming new plantations of fruit trees, and "A. D." (p. 335) has done good service in directing attention to it. Several instances came under my notice last summer, where excellent crops of fruit were had from Apples, Pears, and Plums, which were clearly traceable to the excellent shelter that surrounded the trees.—J. K., *Gunnersbury*.

GARDEN DESTROYERS.

The Vine Weevil.—Having been much pestered with this weevil, I was much interested in reading such a full description of its habits as that which appeared in *THE GARDEN* a short time since, and as it is considered so difficult to exterminate, it may be of use to others if I mention how we deal with it here. The place most infested was a Vinery, where the larvæ did great damage to the roots of the Vines, but, having to make a fresh border, they were cleared out with the soil, and by watching closely for any feeding by night we have been pretty free from them since. Last year by some means or other a few of the beetles found their way into a large Peach house, where they began feasting on the leaves, but by placing a white cloth under the trellis and giving the trees a shake we soon got rid of them. Although others have just lately made their appearance, these are very minute, having evidently just changed from the larva state, and by laying the disburbed shoots in small heaps on the set-off of the back wall, they get under, where they are found in the morning and quickly despatched. By following them up in this way before they are old enough to breed, I do not anticipate any further trouble with them, and if others who have them will adopt the same means to entrap them, I have no doubt that they will soon effect an entire clearance, as I am hopeful we have now done.—S. D.

Sparrows and Primrose Bloom.—Sparrows have picked off the blossoms of Primroses this spring by thousands; they do not eat them, but leave them lying on the ground as if cut off with a pair of scissors. I find, too, that sparrows have been visiting the Gooseberry and Currant bushes in some orchards, destroying the flowers in the same manner as those of the Primroses. The inclement season, I presume, has made their ordinary food scarce, and therefore they attack the first eatable substitute that presents itself; at all events, do not remember such wholesale destruction of Primrose blooms before.—J. GROOM.

The Goat Moth.—I notice a misprint in the article which I sent you on this moth in Vol. XIV. (p. 386); the word "salt" is used instead of "soot." Kindly make this correction. Salt may do harm.—R. M.

A Good Use for Old Logs.—With very little trouble hollow logs can be made to serve a good purpose in the rustic decoration of lawns. A section of a hollow tree, from 1 ft. to 2 ft. in diameter, with a solid rim from 2 in. to 4 in. thick, when cut to a length of about 2 ft., set upon end in any desirable spot and filled with good soil, makes a good receptacle for either seeds or plants. Should a larger surface for planting be required a section may easily be cut 6 ft. or 8 ft. in length, and divided lengthwise some distance above the centre. Thin strips may be nailed across the ends of the larger part, and the hollow filled up with earth, and santed with *Potus* and *Verbenas*, or the hole a strip through the centre may be devoted to low-growing annuals, and the sides and ends to trailing plants. Leave the bark on, and in the split section bore small holes in the bottom for drainage. When plants in these are well established they are very ornamental.—"Rural New Yorker."

GARDENING FOR THE WEEK.

Flower Garden.

Auriculas.—Owing to our keeping the frames a little closer than we have been doing, and removing some of the pots into a warmer house, we have been a little earlier than we otherwise would have been in getting the blooms open, and the continued cold weather has retarded the later sorts so much that we have a good bloom yet. Out-of-doors the finer varieties of the Alpine section are now at their very best; the colours are more brilliant than those under glass, and varieties that have shaded edges under glass are not shaded in the open air; this is not invariably the case, but it is so with some sorts. These hardy Auriculas are not much injured by the weather, and have certainly an exceedingly fine effect amongst Primroses, Anemones, Muscari, spring-flowering Saxifrages, and other plants that are in blossom early in May. Most of the growers are now busy repotting, and directions have been given in previous numbers as to the method of procedure. After repotting the frame should be kept close for a few days, and the plants must be shaded from bright sunshine; the offsets must be kept quite close, especially such as have no roots. I generally place them under a handlight, and then place small bell-glasses over them to keep out the air.

Carnations and Picotees.—We have not yet placed pots of these intended for exhibition out-of-doors. The weather has hitherto been so cold and the frosts so sharp as to quite stop the growth of the plants, and seriously cripple them. Keep the pots free from weeds and the plants from insect pests. If it be intended to flower any of them about three weeks earlier than usual, it will be necessary to place the pots at once in a rather warm house. Blooms of the perpetual-flowering section ought now to be plentiful, and they should be freely produced until after midsummer, for, as the leading flowers die off, the lateral growths push up and continue to produce flowers, though of smaller size, hence the term perpetual-flowering. Young plants must not now be neglected, as they are not unlikely to be, owing to the pressure of work at this season. A cold frame or a cool airy house is the best place for them until the weather becomes warmer.

Dahlias.—Plants of these ought now to be quite ready for planting out, but as yet it would not be safe to do so. The plants should be in pots sufficiently large to prevent their becoming root-bound, and so far apart from each other that they will not become drawn. Admit air freely, removing the lights altogether when the weather permits. See that none of the plants suffer from want of water, and apply it in the morning in preference to the evening while the temperature is so low. The border for the plants may again be forked over.

Pinks and Pansies in Beds.—The growth of these show considerable improvement. Pansies were looking so unhappy some time ago that we had them taken up and replanted. The surface of the Pink beds has been stirred with a small hoe, and since that considerable growth has been made. The plants are quite healthy, and it only requires warmth to induce good growth which will produce plenty of flowers, though late.

Forcing Pinks.—These belong to quite a distinct type from the laced section with white grounds. Anne Boleyn is a good and useful sort, and of newer varieties we have Derby Day, Lord Lyons, and Lady Blanche, the latter a pure white variety with smooth flowers; it is by far the best of the white sorts. Now is a good time to put in pipings of them. I generally strike them in a hotbed on a very gentle bottom heat. The frame should be kept rather close until the cuttings are rooted, when air should be given more freely without moving the pots from the positions which they occupy for a week. When fairly established plant them out in the open border until the last week in September, when they should be taken up and potted in good soil, and the pots should be placed in a cold frame until they are wanted to be placed in the forcing house.

Polyanthuses.—These seem to delight in cold weather; their blooms in the open border appear to be quite uninjured, the colours coming out in their richest hues; our only trouble is the sparrows, which will not let the blooms alone. The plants in pots seemed as if they would exhaust themselves with the production of flowers, and as there is abundance outside, we picked the flowers off the pot plants and planted the whole of them out in rich soil; there they will be no source of trouble until it is time to pot them again in autumn.

Aquilegias.—We grow nearly a hundred of these in pots, and so far they have caused but little inconvenience, except watering them when necessary. Now they force themselves upon one's attention, as the flower-spikes are rising strongly. No one who has only seen the finer species and varieties of these in the open border can form any idea of their delicate beauty when grown in pots. A.

cerulea is particularly beautiful, and the golden-yellow flowers of *A. chrysantha* have an excellent effect either singly or in masses. Give them plenty of air, water freely at the roots, and syringe to keep the leaves clear of red spider.—J. DOUGLAS.

Stove.

Continuous Summer Blooming Plants.—Such subjects as have a natural habit of flowering for a long period during the summer months, or of producing growth and flowers alternately at different times during that season, now require such attention as will further their disposition in that respect. 'Allamandas grown in pots and tubs, if treated in accordance with their requirements, will now be well furnished with bloom, and, as already recommended, they must be regularly supplied with stimulants, otherwise there would be a deficiency of the continued vigorous growth indispensable to the full production of flowers. The same applies to plants that are turned out, but that have limited root-space; in their case a surface dressing composed of one-half rotten manure, the other sandy loam, will be found very useful, as the enriching elements which it contains will get washed down to the roots in the operation of watering. Similar treatment as regards manure water will answer for *Aristolochias*, *Passifloras*, *Dipladenias*, and the strong-growing *Thunbergias*, and such as are planted out should be surface-dressed.

Hibiscus sinensis.—Of this there are several varieties, all of which have naturally such a free flowering disposition, that they will bloom in a very small state; consequently, they are alike useful in small and large houses. Both the double and single varieties are alike handsome. One considerable advantage attached to the plants is that they will bear cutting in to almost any extent, their free habit of growth enabling them to break out and grow away after being headed in much quicker than most hard-wooded plants. A few large specimens may be grown on to occupy the centre or most prominent position in large stoves, but small or medium-sized plants will generally be the most useful; they should therefore be propagated by putting in a few cuttings two or three times during the year. Points of the shoots 4 in. or 5 in. in length, or young breaks from plants that have been cut in taken off with a heel, will root with ordinary treatment in a few weeks. They will succeed in either peat or loam, but where free-growing subjects are thus accommodating, loam of a good free description is usually the best, as in it they mostly have a freer disposition to flower.

Stephanotis.—When planted out with a moderate root-run, and room for the head to extend sufficiently in a somewhat cooler and drier atmosphere than the generality of warm stove plants require, the *Stephanotis* will bear much the greatest amount of flower, and individual plants of it will keep on producing successional bloom much longer than when grown in pots; yet for conservatory decoration—for which purpose from its agreeable perfume it is so well adapted—there is an advantage in growing some in pots, as under this system of cultivation the time of their flowering can be regulated, and they can be transferred during the summer months to structures, where the heat is not sufficient to grow them continuously; but where they have to be placed whilst in bloom, even during the warmest months of summer, in conservatories and greenhouses, I have found it well to bring them on into flower a little slower, and to gradually inure them to the lower temperature before the blooms were expanded, as in this way they will last very much longer than if allowed to open in strong heat, and afterwards transferred to cooler quarters. The *Stephanotis* is so accommodating, that it will succeed in a lower temperature both summer and winter than that in which many people ever try it. It can be grown in a house not kept higher than from 45° to 48° through the winter, and during the summer months with somewhat less artificial warmth than is usually considered necessary for the majority of intermediate house plants. Thus treated and kept in pots 10 in. or 12 in. in diameter, without disturbance for years, they will not make shoots more than 5 ft. or 6 ft. in length during the season, but will bloom from almost every joint, the flowers lasting double the length of time they will when grown hotter. Managed in this way, they will ordinarily not open their blooms before June, but will make beautiful objects for greenhouse decoration, a purpose for which they require no further training than running the shoots temporarily round a few sticks. After the flowering is over they may be slightly cut in and replaced in their regular quarters; the growing shoots should then be trained near the glass, and there allowed to remain until ready for being similarly employed the succeeding season. By the use of manure-water whilst growth is being made after flowering, I have had plants in a satisfactory condition in the same pots for five or six years without any renewal of the soil. I have gone thus far into detail with this method of growing this plant on account of an impression which often exists, that it cannot be cultivated without more heat than some have at command; but when grown as just described, it can be kept without any loss of leaf through the winter

in a lower temperature than it will bear if grown in hotter quarters during the summer.

Potting Newly-struck Plants.—Cuttings of the more generally-grown climbing and bushy-habited stove plants recommended to be put in about the end of March will now be well rooted and have got sufficiently inured to the full air of the house to admit of their being potted. As to the time when such work should be carried out, I have found it best to steer between two courses, the one of moving the plants too soon from the little pots or pans in which they were struck, and the other, which is still worse, of letting them remain until their roots had got much entangled and the wood in a somewhat hardened condition, in which latter case the after-growth is never so free as it otherwise would be. The great point with stove plants, the majority of which are quick growers, is to keep them during their early stages sufficiently near the glass to counteract the natural disposition of a moist, close atmosphere to induce extension at the expense of that solid, short-jointed, and robust growth which is essential to vigorous health and ultimate free-flowering. As to soil, those plants that will grow in loam, especially in stoves where a strong heat is maintained, will generally flower freer in it than in peat, consequently it is better in such cases to use loam; but I would by no means recommend its employment for plants that have their growth unduly restricted; for instance, in the case of *Dipladenias*, for which it is sometimes recommended, the results are so far against it, that the best flowered examples out of the many I have seen when grown in loam have not more than half equalled the same species or varieties when grown in peat.

Bouvardias.—Wherever there is a continuous supply of cut flowers required through the autumn and winter, these plants will be found to play a most important part in furnishing it, that is, if they be really well grown, but on this very much depends. Where grown strongly and vigorously, if kept sufficiently warm through the winter, they will, as the first flowers produced from the points of the shoots are removed, keep on yielding a succession of bunches from three or four of the lower joints one after the other as they are cut, whereas if indifferently treated, and the shoots are comparatively weak, not only are the trusses of flowers produced proportionately small, but the successional yield is likewise little; consequently, when grown from cuttings struck in the spring up to a blooming size in the course of the summer no time admits of being lost. Cuttings put in in March will by this time have made considerable progress, and should now be ready for transferring singly to 3-in. pots. If the treatment has been such as recommended, the superiority of the plants produced from root-cuttings over those that are made from the young shoots will be apparent. The points of the growths should be nipped out in order to induce them to break freely. They will succeed in either peat or loam, but where the latter is to be had of good quality, and to it is added some well-rotted leaf-mould, sand, and fully decomposed manure, a mixture will be formed that will push them on in the way desired. They should be kept in a warm, genial, temperature with a moderately moist atmosphere, plenty of light, air in the middle of the day, and a thin shade from bright sunshine, until they have got fully established. *B. Vreelandi*, one of the dwarfest and most compact of *Bouvardias* and a very free-flowerer; *B. jasminoides*, white and free in regard to growth; *B. Humboldtii* corymbiflora, white, with very large flowers and bunches; *B. Hogarthi*, scarlet; and *B. elegans*, also scarlet, finer and larger than *Hogarthi*, from which I believe it is a sport, will all be found sterling kinds. Plants that were cut back some time ago, and which have now broken freely, if not already partially shaken out and repotted, will be in a condition to be treated in that way, using compost like that recommended for the younger stock, but in the case of these there is no need to push their growth on so fast as the young plants, for, having all the season before them, they have time sufficient to attain a size large enough to be convenient.

Gesneras.—The rich-veined velvety-leaved section of these, which, independent of their handsome foliage, form such conspicuous objects when in flower, should be started at two different times with a view to affording a succession, commencing with those first that bloomed the earliest, and that have therefore been the longest at rest. If the bulbs have been allowed to remain in the pots in which they were grown, the soil permitted to become dry, and they have been stowed away in a situation sufficiently warm to keep them in a healthy state, they will now be fresh and plump, or if removed from the pots and kept in dry sand in a like temperature, they will be in good condition for starting; they should therefore be placed in pots or pans, drained and filled with light open peaty soil or loam with which has been incorporated a liberal quantity of leaf mould and sand, keeping the soil in rather a dry state until they have commenced to grow, or there is danger of their scaly roots rotting. They should be covered about $\frac{1}{2}$ in., not more, and put in a moderate stove temperature, and when

the shoots have appeared 1 in. or 2 in. above the soil they should be moved singly into 3-in. pots.

Luculia gratissima.—This splendid autumn-flowering plant, though comparatively insignificant in a small state compared with what it is when planted out so as to cover an end wall, or other position that admits of larger development, is, nevertheless, very effective grown in the form of moderate-sized specimens in pots; a way in which it is especially useful where there is a warm conservatory. Small plants that have been headed back after flowering, partially shaken out and repotted, will now be in a condition to move into others of a larger size, in which they are to bloom, giving them good turfy loam, to which has been added a fair sprinkling of sand. If any of the shoots show a disposition to so far take the lead as to impoverish the rest, they should have their points pinched out, and the branches of all ought to be slightly tied out so as to give each sufficient room; keep them well up to the light, and do all that is possible to encourage strong growth, for upon this and its being well matured depends the ability of the plants to flower satisfactorily. Old-established plants of this *Luculia*, used for permanently covering back or end walls, that have been cut back after they have done blooming, should, as soon as the young growth begins to move freely, be well supplied with manure-water, or when this or plants of a similar character are grown in conservatories or other structures, in which the smell from liquid of this description would be objectionable, a good sprinkling of Standen's manure will be found to answer all purposes. It needs nothing more than to be scattered on the surface, as the invigorating elements which it contains will be washed down in the ordinary process of watering.—T. BAINES.

Indoor Fruit Department.

Vines.—If, in successful Vine culture, one matter demands a larger share of attention than another it is the constant battle which we have to wage with insect pests; and amongst these red spider and thrips are the most formidable. The latter, if taken in time, can be effectually exterminated by fumigation, but the former does not yield so readily when once it has gained a footing, and this shows how important it is to adopt preventive measures. These consist in keeping the roots well supplied with moisture and nourishment, the atmosphere charged with ammonia, at all events during the earlier stages of growth, and judicious and regular ventilation. A check through inattention to any of these matters is not unfrequently instrumental in producing bad results. Watchfulness in regard to such matters is more especially necessary this season, considering the amount of artificial heat that has been required in order to maintain anything like a growing temperature, and the consequent aridity of atmosphere and surface drought of borders. If red spider has already appeared, first look to the conditions here indicated, and then sponge the affected foliage with soapy water. The much belauded remedy of applying sulphur to the pipes is as useless as it is dangerous in the hands of the inexperienced. Late Vines will now or shortly be in flower, and to make assurance doubly sure, frequently tap the rods, in order to disperse the pollen. Muscat Hamburg, Mrs. Pince, Muscat of Alexandria, and Lady Downes, if gone over separately with a camel's-hair pencil charged with pollen from other varieties, will not only set more freely, but will swell more evenly. Take off all superfluous bunches before they are in flower; what are left will set more freely, and the laterals should also be stopped at the same time, as growth should continue unrestricted during the time of flowering. If the borders be in any way dry, water liberally with warm water. One is constantly being asked how often and when do you water your inside borders? but it is not possible to satisfactorily answer such questions; all that can be said is that they may be watered freely provided the drainage be good, and at any time rather than they should suffer in the least from drought. Of course, the most unobservant would know better than to produce excessive atmospheric moisture by watering at the time when the Vines are in flower, and when they require a somewhat dry air in which to set their fruit freely. Intermediate Vineries will now need daily attention to tying down, regulating, pinching the shoots, and thinning out the berries. This latter work will not permit of procrastination, nor indeed will the former without injurious results. If lateral growths be left to develop into a thicket of foliage and shoots that have eventually to be removed wholesale, one need not wonder if shanking ensues. Grapes colouring should have free ventilation during all weathers, and if dull fumes must be kept up, high night temperatures should be avoided. If there be any danger of the border getting dry do not scruple to water, even though the Grapes are ripe; such watering will not harm them if abundance of air be afterwards given to carry off excessive moisture. Outside borders that have been artificially protected should now have the covering material removed, the soil pointed over, and to prevent cracking, a coating

a couple of inches thick of horse droppings should be applied. Where shutters or other water-tight coverings have been used watering may be requisite, therefore the borders should be examined, for, though the present crop may have finished perfectly, it should be remembered that next season's fruit is, so to speak, manufactured this season, and if there be any lack of water now the consequences will be apparent enough next season, inasmuch as tendrils-like "shows" will be produced in lieu of well-developed ones. As soon as recently-planted Vines have taken a firm hold of the soil, free growth should be encouraged by closing the ventilators early on sunny days and running up the temperature to 90°. Syringe both Vines, walls, and floors at the time of closing, and conserve the moisture in the border by keeping it well mulched with stable litter.

Pines.—After such a protracted sunless time as that which we have had, as soon as bright days occur, recourse must be had to shading till the plants get inured to the change. The two or three sunny days which we have had have already browned the foliage of the sturdiest plants, and, though shading is not desirable, it is better to employ it than to have the foliage scorched. Supply those plants that are swelling off fruit with liberal quantities of tepid manure water, and keep up abundant atmospheric moisture by means of frequently damping the floors and walls, and keep the evaporating pans charging with manure water. Autumn fruiterers ought now to be showing, and as soon as this is perceived, well soak them, and increase the bottom heat to 90°. Any that are required to show should still be kept dry; a check in that way will soon have the desired effect, i.e., if the growth has been matured. Pot on succession plants; they should never be allowed to get pot-bound till growth has been completed, and then such restriction is desirable.

Peaches and Nectarines.—The earliest kinds of these now ripening should be exposed to a free circulation of air, in order to give them flavour; therefore, if the cold weather which we are now having continues, firing will still be required, in order that the desired ventilation may be given. Pinch off or tie aside all leaves that shade the fruit, and stop all unnecessary growths, an operation which will have a marked effect on the swelling of the fruit. Discontinue syringing, but still maintain a moist atmosphere in order to keep down red spider. The shoots in succession houses will require tying in, and only a sufficiency should be reserved for next year's fruiting. Any others would only have to be removed at the winter pruning, and in the meantime would exclude the permanent shoots from that full exposure which is necessary for the formation of vigorous fruit buds. Inside borders require abundant supplies of tepid water, and after this has been given, mulch them with stable litter, in order to prevent too rapid evaporation, and to conserve the heat communicated. Late houses may now be finally disbudded; all surplus fruit may be pulled off at once, and there need then be no fear of failure at stoning time; it is leaving them on so long and in such numbers which nine times out of ten causes failure at this stage. Water borders liberally, and syringe the trees vigorously, to keep down spider, and for green or black fly, fumigate with Tobacco paper the moment any are observed.

Figs.—The first supply of fruit is usually obtained from trees in pots, a system of culture which has many advantages, and which is, perhaps, the best for an early supply, but it has also its disadvantages, and of these one of the greatest is that fine flavour as regards the first crop is almost an impossibility without seriously damaging the prospects of a second crop. Owing to the root space being so circumscribed, and the demands made by both foliage and fruit so large, frequent waterings become a necessity, in order that the fruit may gain that fulness of flavour that can only be imparted by a partial withholding of water and full exposure to sunshine, both of which conditions, under the circumstances, would be inimicable to the second crop; therefore, recourse must be had to what I shall call compromissorial treatment, that is, the pots should be plunged in a bed of leaves, when less water would be required, and, when necessary, it should be applied freely, after which thickly cover the surface of the pots with droppings, to prolong the necessity for further watering as long as possible. The fruits should be gathered the moment they show the least symptoms of cracking, and they will then keep for three or four days in good condition. As soon as all are gathered remove the old top-dressing and substitute fresh, rich compost. Recommend syringing and water freely with liquid manure, and if red spider has gained a lodgment, syringe the foliage with a weak solution of the same liquid. Old and free-bearing trees in open borders cannot have too generous treatment; shut up early, well ply the syringe, and keep the growths restricted by pinching a few of them at intervals of a few days, a practice which insures successful supplies of early autumn fruit.

Melons.—Plants swelling off their fruit will require careful management as regards watering, as an overdose might induce splitting, whilst a meagre supply would be a sure precursor of red spider,

which soon destroys the foliage, and unless this continues good to the last the fruit will be flavourless and insipid. It is therefore a good plan to cover the bed with non-conducting material, which, as a matter of course, prevents the too rapid evaporation of moisture and the necessity for frequent waterings. Elevate the fruit above the foliage in order that it may receive the full benefit derivable from light and air. Succession plants should be encouraged to make fruitful rather than free growth; plenty of air on all favourable occasions, with a medium amount of air moisture, will insure the former, whilst a close, muggy atmosphere will as certainly insure the latter, but there will be no fruit. Plant out for the late summer's supply, and make another sowing if the plants cannot be depended on for successional fruiting.

Kitchen Garden.

Nothing can make satisfactory growth or progress whilst the weather continues so cold as it now is, and, unfortunately, at present—May 10th—there are no indications of a change; it will therefore be necessary to continue protection to all tender vegetables, by way of accelerating growth. Peas should be screened from the north-east wind by evergreen boughs; Carrots and Radishes in open borders, by placing over them Hazel spray; and Cauliflowers that have recently been planted out, by drawing the soil well up to them. Potatoes and French Beans, as they emerge from the ground, should for the present have the soil drawn quite over them, and those that have got too high for that should be covered with litter, so long as frost seems likely to occur. All such labour may seem to some unnecessary, but it is not so, as it frequently saves the crops on which it is bestowed, and certainly this season early crops are required, considering the general slaughter which the winter has made amongst all culinary plants. Easterly winds, cold though they be, have some redeeming qualities, and one of them is drying the soil, which has allowed surface-stirring amongst seedling crops, and also bringing up arrears as regards Potato planting and seed sowing, such as Carrots, Beet, Broccoli, and winter greens generally, all of which, if not yet sown, should have early attention, as should also the sowing of French Beans and Scarlet Runners; the latter should be sown in shallow trenches, to admit of liberal waterings in the event of drought setting in. The earliest sown Spinach ought now to be fit to gather, therefore the remains of the winter Spinach may be dug or trenched in, when the ground will be suitable for Beet, Peas, Broccoli, or Cauliflower. In order that no unnecessary exhaustion of the soil may take place, the old stems of Brussels Sprouts, Kales, or Broccoli should be cleared off as soon as the produce is used, and as soon as practicable let the ground be lined out into Celery trenches, or be dug or trenched according as it is required for the forthcoming crop. There should be no fallows, accidental or otherwise, in kitchen gardens; on the contrary, each successive crop should, as it were, prepare the way for the one that is to follow it, and in furtherance of this notes as to dates and positions respecting the various crops will require to be kept. The labour of keeping such a diary soon becomes a pleasant duty, but those who do not care to take this trouble—so-called—but who crop on the haphazard principle, would at all events find it advantageous to adopt the simple rule of never allowing two crops of a like nature to succeed each other on the same plot of ground, but should endeavour to have the character of each successive crop as remote as possible. Several of what may be termed half-hardy esculents will now demand special attention. Amongst these are Tomatoes, which should be hardened off preparatory to planting out on south borders or against walls at the end of the month. The same may be said of Capsicums and Chillies. Ridge Cucumbers and Vegetable Marrows may be planted out at any time, if they can be afforded the protection of hand-lights, and by way of starting them quickly into growth, a slight bottom-heat is desirable, and easily created by the use of lawn mowings and stable litter; about 2 ft. in depth will be ample, and as the material cools down the roots of the plants will soon sweeten themselves in it. Seedling plants of Thyme, Basil, Sweet Marjoram, and Sage should be pricked out under shelter, and may be permanently transplanted in the open ground about the end of the month. All kinds of herbs have suffered severely, so much so, that new plantations of them will be a necessity, and provision should be made accordingly by pricking out a sufficiency of each sort. Sow Lettuces and Radishes once a fortnight; the former should now be sown where the plants are to grow, as transplanting in dry weather entails much labour in watering, and even if this be afforded the plants receive a severe check. Asparagus being now in full bearing, Seakale may be dispensed with, any yet covered should therefore now be exposed, and gaps in the plantation be made good by dibbling in sets made from pieces of roots 3 in. or 4 in. long. Salt is a valuable fertiliser for this esculent, and should be scattered over the surface after the ground is dug. Cut off seed-stems as produced and thin the crowns to one shoot only.—W. W.

ORANGE FLOWERS AND ORANGES FROM THE SOUTHERN STATES.*

By W. B. BUSH.

In Florida the Orange, Lemon, and Lime grow wild and are found in abundance. In Louisiana and Mississippi they are grown from seed. The seeds are planted in early spring or in hotbeds in January. When one year old they are transplanted in a nursery arrangement. At the age of two and half years they are budded, *i.e.*, the seedlings are of the sour variety, and to produce sweet Oranges fully matured buds are taken from bearing trees and inserted. This is done to render the tree more hardy, since the sweet seedlings are subject to a root disease called heel, while the sour seedlings are not. Hence, Orange growers resorted to this means to produce sweet Oranges. The trees are transplanted at the age of four years into orchards; at the age of six flowers first appear, and at ten years the trees are called full bearers.

This beautiful evergreen is found in every civilised country where the climate is favourable, and in colder countries it is the most cherished ornament of the hothouse. It flourishes in the most southern limits of the United States, largely in Florida, and to a considerable extent in Mississippi and Louisiana, south of the lakes. In Mississippi and Louisiana they are favoured by the lakes tempering the cold north winds. There seems but little difference between these States as far as their favourable localities are concerned. The tree, however, requires delicate cultivation and studied treatment. In the year 1816 Oranges were introduced as ornaments to the States by the French. In 1830 an Orange tree in a box in bloom brought 400 francs, and about this time some attention was paid to Oranges by horticulturists, and blooming trees in boxes were sold at from 50 to 100 francs in New Orleans. The beginning of the cultivation of Oranges for fruit in the South dates back to 1848, when numbers of trees were planted, but in January, 1856, a cold wave from Texas brought the temperature down to 19° Fahr. above zero, and the large proportion of the trees were killed. Not much attention was paid to the cultivation afterwards until 1867 and 1868, and since then Orange growing has been quite successful and assumed commercial importance.

In the case of healthy trees, the time of flowering is from the beginning of February until April 10; unhealthy ones are found in bloom sooner or later. The last week of February finds most of the trees blooming. The humidity of the atmosphere materially affects the flowers; when too wet the pollen heads are injured and the secretions are imperfect. Dryness has a similar effect on the pollen and nectar, but does not affect the secretion of oil. When the temperature is too low, but few flowers are fructified, the oil cells are limp, and no nectar is secreted. The most favourable temperature is about 68° to 78° Fahr.; under 60° Fahr. flowers are blighted. When bees are found collecting the nectar, the conditions are favourable for the development of flowers and fruit, and then the flowers contain their most agreeable odour.

An ordinary tree will yield from 2 lb. to 10 lb. of flowers, ordinarily about 7 lb. As soon as the petals begin to fall a canvas is spread under the tree, and by brisk shaking the petals will fall with some leaves, which can be easily separated. The time when flowers are most fragrant is early in the morning; late in the day the odour is greatly diminished. Prior to the late conflict, negroes collected and sold Orange petals in New Orleans. A saucful (about 2 oz.) was measured out, put upon a china plate, and set in the room, for which the negro received about 50 cents. From two to three plates would perfume a room for a week. Orange flowers produced in the extreme southern borders are believed to possess a stronger odour and more oil. The difference is accounted for in this manner: In the Tropics and semi-Tropics the trees do not begin to bear very much until about twenty years old, while in this country they begin at about seven. The development is more rapid, the tree more vigorous, and it is reasonable to suppose a better development of odour in the flower takes place. The flowers are also more fragrant and the fruit more juicy, but not so sweet as in some other countries.

Orange flowers, when placed in direct sunlight, in the course of two days lose their odour. In diffused daylight they retain it for at least three days, and in a dark humid atmosphere the odour is quite distinct after one week. When bruised, they lose their odour in half of the time stated. I have had no means of experimenting as to the amount of volatile oil, but believe that the better plan for the pharmacist is to have the petals hermetically sealed and to make his preparations direct.

Orange-flower water is one of the most agreeable vehicles for nauseous medicines that we have, and when the pharmacist can make fresh preparations they will be fully appreciated, and the

expense will not be greater. The syrup of either flower or fruit has no superior, especially the syrup of the fruit. A honey collected from Orange flowers is very fragrant with the Orange odour. The flowers, placed in tin cans and sealed up, are known to have retained their odour unimpaired for nine months. As a perfume they have no equal. To sit under a tree when in full bloom is delightful, and the fragrance intoxicating. If any one has made the syrup of Orange from the fresh juice of the fruit and used it, he will not want to use any more which is made from simple syrup and a few drops of the oil of the rind.

PLATE CLXXX.

MRS. BATEMAN'S LILY.

(*LILIUM BATEMANIÆ*)

Drawn by Mrs. DUFFIELD.

HAVING received permission from Mrs. Bateman, a well-known lover of Lilies, we had the pleasure last autumn in naming this fine new autumn-flowering plant *Lilium Batemanii*. It grows from 3½ ft. to 4 ft. high, and with suitable cultivation might be expected to attain double that height. It has a slender, light green, somewhat rough stem, inclined to bronze at the insertions of the lower leaves; the latter are crowded, alternate, long and slender, arching downwards. The flowers are semi-cup-shaped with spreading segments, somewhat recurved, medium sized, of a deep apricot tint, and unspotted. They are produced in umbels of from four to eight or twelve, not unlike in tint those of *Thunbergianum venustum*; but the plant, as to bulb, habit of growth, foliage, and time of flowering, resembles very closely *L. Leichtlini* or *Maximowiczii*, to which it is closely allied. This new Lily first flowered with us in 1875 from some small bulbs obtained from Japan in rather poor condition; we were much puzzled by its nondescript appearance, for the flowers reminded us strongly of *Thunbergianum venustum*, while the strong growth and habit were more like those of *L. croceum*. The plant being dwarf, weak, and poorly developed, we postponed that year any decision as to its character till we could obtain stronger specimens. Fortunately, in the winter of 1877-8, a large number of bulbs from Japan, under the name of *Talsta-juri*, made their appearance in the market; they were small in appearance, and much resembled those of *L. Leichtlini*, having broad, stout scales, with the front tier reaching only half-way up the bulb. Bulbs of *L. umbellatum* are in general large and flatter, with scales nearly well up to the top; and those of *L. Thunbergianum* have more numerous, slender, and narrower scales, reaching vertically higher than these up to the apex of the bulb. We purchased and planted a lot of these bulbs, and, during growth, at first thought we had got the true *L. Leichtlini*, comparing them with some of the true plants growing very near, but later on a difference appeared in stems and foliage; the former were too rough and green, whereas those of *L. Leichtlini* were smooth and dark coloured; the foliage, too, was large, more crowded, and arching, whereas in *L. Leichtlini* it is more sparse, erect, and acute; lastly, the flower-buds were blunt at the tip, marked with red, and arranged in an umbel; those of *L. Leichtlini* more elongated, green at the top, and arranged on a spike. When the flowers expanded we saw at once that we had our old friend before us which had so puzzled us in 1875. We have here no doubt a hybrid; it may be between *excelsum*, which it much resembles in shape and substance of flower, and *L. Maximowiczii* to the bulb, of which its bulb is very similar. As an intermediate form it is most interesting; as a decorative autumnal form it is floriferous, elegant, and striking, and well worthy of a good place in the garden. It will, we should think, be placed in the Martagon section along with the other three above-named forms. In this section we have many superb forms, among which we may place first the very beautiful early-flowering, canary-coloured *L. Szovitzianum*, with its twenty or thirty bell-shaped, broad-petalled flowers beautifully spotted; *excelsum*, with its tall, peculiarly graceful, hanken-coloured flowers, so exquisitely scented; *tenifolium*, elegant for its slender foliage, and handsomest among dwarf Lilies for its tall spike of scarlet bells; *Humboldtii* and *pardalinum* for their tall, floriferous spikes of light orange flowers, variously spotted, and tipped with carmine or scarlet; *L. parvum*, one of the most beautiful and floriferous, small as to its individual flower, but excessively graceful, and very tall growing; *L. columbianum*, remarkable for its golden bells; *L. polyphyllum* for its symmetrically, purple-spotted, bell-shaped, white flowers; the blood-red *L. dalmaticum*, 6 ft. to 8 ft. high, bearing thirty to forty flowers; *L. Hansoni*, a very early, stout-growing kind, likely, when better known, to be an universal favourite; and last, but not least, *L. Leichtlini*, long acknowledged to be, with its delicately yellow-tinted, purple-spotted flowers, one of the most graceful Lilies in existence.

ALEXANDER WALLACE.

* From a paper read at a meeting of the Philadelphia College of Pharmacy in January last.

THE LILY OF THE VALLEY (LILY OF THE VALLEY)

VEGETABLE CULTURE IN MARKET GARDENS.

THAT ordinary vegetable crops pay the grower well there can be no doubt, and the soil cannot be better employed than in producing good vegetables. In country places every cottager can grow nearly enough of them for the maintenance of his family; land is cheap either in the shape of allotments or otherwise, and, therefore, a good supply of wholesome vegetable food can be obtained at little cost. Londoners, however, and the inhabitants of other large towns have to depend upon the market for their supplies of vegetable food, and although the market gardener often gets but little for some of his produce, the consumer has to pay comparatively high prices for all he purchases in that way. If growers could sell their produce direct to the consumer they would get better profits than they now do, and the consumer would get his vegetables much cheaper and better. Sometimes good Cabbages, Peas, and similar produce may be bought from hawkers at very low rates, but in the market, owing to salesmen's commission and other expenses, people have to pay as dearly in proportion for vegetables as they do for animal food. All things considered, however, market gardeners make a good per centage on the money invested in their business, the real sufferers being the consumers. To have vegetables wholesome we must have them fresh, and this the poorer classes seldom get. The quantities of such produce sold weekly in London are enormous, and yet at times there is room for more.

GARDEN FARMS.—What may be termed garden farms are considered the most profitable, inasmuch as the facility of intercropping, &c., is greater than when market gardening proper is carried on; the land can be cropped with Corn or other crops, and it is moreover kept clearer of weeds than if either farm or garden crops alone were grown.

Mr. W. Glenn's farm at Barking (says Mr. Evershed, in the "Agricultural Journal") is a good illustration of a well-managed garden farm. It consists of 150 acres of gravelly loam, made rich and friable with manure, and otherwise kept in the highest state of cultivation; the land is entirely under vegetable crops, with the exception of 18 acres of permanent pasture, and 16 of wheat on the stiffest land. The vegetable portion is thus appropriated: Potatoes, 34; spring-sown and Lisbon Onions, 15; Cabbages (red and others), 13; seed beds, 2; Carrots, 7; Parsnips, 9½; French Beans, 6; Scarlet Runners, 3; Vetches and green food for horses, 4; Parsley, 1½; Willow and Osier beds, 1½; Wheat, 13; Mangold, 1½; Peas, 8; Asparagus, 1; men's allotments, 1; Cucumbers and Melons, 2; seeds, 1; small crops, such as herbs, &c., 11. Twelve horses are kept to cultivate the farm, convey the produce a distance of 8 miles to London, and to cart manure. The sums paid for manure, exclusive of cartage, during three years are £211, £261, and £278; from 400 to 700 bushels of soot are also used in each year. About one-half of the manure is purchased at 3s. or 3s. 6d. per ton, and is drawn from London in the empty waggons; the remainder is bought at 5s. per ton at the railway station or quay. Some other manures, including spent Hops from an adjoining brewery, are also brought on the farm. The labour bill, including beer, is £1500, or £10 per acre. On June 17, the number of labourers employed, including 10 women, a wheelwright and a salesman, was 35, and their wages amounted to £30 per week. During the winter five women are employed preparing goods for market, bunching Leeks, pulling and bunching Greens, putting up Onions, &c. The implements of the farm, besides carts and market waggons, consist of common ploughs, a double-breasted or ridging plough for moulding up Potatoes, Beans, and Peas, and some hand-drills. A small patent tool which resembles a Dutch hoe set on wheels must be mentioned, because its use

shows the mechanical effects of manure and good farming in making the surface friable. It is not uncommon for a man to push this little implement over two acres in a day, cutting up all the weeds between the wide rows of the garden crops. A Willow bed supplies bunching rods for tying bunches of Onions, Greens, &c. The Willow plants are set 18 in. apart in the rows, which are 2 ft. asunder, and the bed lasts twelve years. Others of coarser habit are grown to make baskets for vegetables, and the cost of the baskets with a few sacks exceeds £50 a year. The cost of baskets, transit and market dues, are estimated at 50s. per acre in large market gardens. The weekly wages of hands vary from 5s. to 10s. for boys, 10s. to 14s. for women, and 15s. to 25s. for men. Most growers, however, get a good deal of their work done by contract at the following rates: Hoeing Cabbages at 2 ft. apart by 15 in. first and second time 5s. per acre, third hoeing 4s 6d.; Potatoes, 3s. to 4s. per acre; Carrots, broadcast, £3; Onions, broadcast, £4; lifting early Potatoes with fork, sorting them into three sections, and placing them in baskets, 8s. per ton, or from 24s. to 30s. per acre; gathering Peas, from 4d. to 6d. per bushel; and lifting, bunching, and loading Carrots, 7s. per twenty dozen bunches.

CULTURE OF THE SOIL.—Every vacant piece of ground not required to be immediately cropped after the first week in November is deeply trenched and heavily manured, and this even amongst fruit trees. To most people the trenching of ground under fruit trees would seem undesirable, on account of the injury that their roots might sustain, but as it is done every alternate year, at least, the roots never get so large that their removal would injure the trees; of course the trenching does not come nearer their trunks than 6 ft. or 8 ft. Mr. Dancer, of Chiswick, practises this method, and he finds that the trees are benefited by it; he, however, makes one provision, viz., that it must be done every year, and that plenty of manure must be added. Those who grow vegetables between fruit trees gain immensely by the deep stirring of the soil, and where that is not done, digging and manuring generally receives attention. Mr. Willmot, of Isleworth, seldom grows vegetables between fruit trees, but he manures and digs the land frequently. Mr. Yeldham, of Hammersmith, has proved by experiment that the trees which yielded the best crops and best fruit were those that received annually a fair amount of manure, forked in during the winter, and that had the soil kept free from weeds or crops of any kind during the summer. Trenching is considered by market gardeners to be of the greatest importance in the case of land about to be cropped by early vegetables, such as Cauliflowers, Peas, or Lettuces, and also for root crops, such as Parsnips, Carrots, Beetroot, Salsafy, or Scorzonera, or other deep-rooting plants. Land that is to be planted with the root crops just mentioned is generally that which was trenched and heavily manured the previous year; and fresh manure is never added immediately before such crops are sown, as freshly-manured land would cause the roots to fork, instead of growing straight, and thus considerably reduce their market value. In trenching, a staff of men are placed five or six paces apart, and each works till he meets his neighbour. The manure, if any is applied to the surface soil, is thrown into the bottom of the trench, and the soil from the bottom of the trench, which is usually 3 ft. deep, is brought to the top; this practice is carried on year after year. At Walham Green, Fulham, where land is chiefly devoted to market garden crops, the most has to be made of it, owing to the high rental which it realises. A plot of several acres, for which £12 per acre is paid, consists of fruit trees undercropped with vegetables and flowers, a plan which is said to be highly remunerative. The produce of fruit alone one year with another realises £25 per acre. Plum and

Pear trees are planted alternately in rows, a plan by which the taller-growing Pears throw very little shade on the Plums. Not a little of the success which attends the undercropping of vegetables, fruits, and flowers, however, is due to the large quantities of rich, well-rotted manure and manure water that is obtained from a clean and well-managed piggery, the occupants of which consume the superfluous vegetables and fruit.

All vegetable refuse, except what is really necessary to burn, is turned to good account by the market gardener. The stumps of Brassica and Borecoles are carted away to the manure yard and built into stacks, and when dry are used by the labourers for making fires to boil their kettles. Good farm-yard manure is, however, preferred to artificial by London market gardeners. Market growers use manure in what some would term "extravagant" quantities, upwards of 80 tons per acre being frequently used at one application, and yet it has to be purchased and carted six or seven miles. Soot is also freely used in the market grounds in addition to stable manure, and the condition of the crops tells how much they are benefited by it.

Root Crops.

In these may be included Potatoes, Beetroot, Parsnips, Turnips, Carrots, Salsafy, &c., all of which form important market garden crops. In London market gardens immense quantities of Parsnips and Beetroot are grown, but the chief supply of Carrots sent to market during the winter is grown near Weybridge, Esher, and Cobham, in Surrey, where large fields are devoted to their culture. If possible, in market gardens all root crops are cleared off the ground in time to admit of the ground being deeply trenched and ridged. Preparatory to sowing, the surface of the soil is levelled with steel forks, breaking it as fine as possible in the operation, and finishing off by smoothing the surface with a wooden rake. Some growers even roll it afterwards, but this is only done in light ground, and when the soil is dry. Many open the drills in the morning and sow the seeds in the afternoon, thus ensuring, they affirm, earlier germination than would otherwise be the case. As a rule, market gardeners select a piece of ground for root crops that has been heavily manured the year before and cropped with Cabbages, Cauliflowers, French Beans, Celery, or similar vegetables which have been cleared off in time to allow the ground to be trenched and ridged for at least a month prior to levelling it down for sowing. The average cost of preparing these crops for sale is about 8s. per twenty dozen bunches, viz.—digging up roots, 2s. 6d.; washing same, 1s. 8d.; bunching, 3d. 4d.; cost of Willows for tying, 6d.; and to this are to be added carriage and commission. Beetroot is not bunched on account of its being easily damaged by rubbing.

PARSNIPS.—In market gardens Parsnips are always sown as soon after the middle of February as possible, provided the ground is moderately dry and warm, and crumbles freely with the fork. Preparatory to sowing, the ground is levelled, and the soil well broken in the operation, and finishing off by raking the surface smooth with a wooden rake. Shallow drills are then drawn for the seeds at about 18 in. or 20 in. apart; and after being sown they are covered in by the feet or the back of a rake, and the whole is smoothly rolled. Sometimes white or green Cos Lettuces have been planted in rows at the above distances, and the Parsnips are sown in lines between them. In either case, Lettuces are planted—if not first, they are put in afterwards; and as the Parsnips take a long time to germinate, the Lettuces are removed before they injure them. As soon as the Parsnips are fairly up and growing, they are thinned out a little, and when well established, they are finally thinned to 9 in. apart. The

Lettuces, when marketable, are tied up and removed before they can choke or otherwise injure the Parsnips, which afterwards soon grow rapidly, no further care than occasional hoeing being then bestowed upon them. The bulk of roots per acre is enormous, many of the specimens measuring individually 7 in. and 8 in. in diameter at the shoulder, and 20 in. to 24 in. in length. The variety grown in market gardens is the Hollow-crowned, a capital sort, that produces roots from 4 in. to 6 in. in diameter at top, and from 10 in. to 20 in. in length; and the crowns are, as a rule, buried a little below the surface soil. Parsnips are not brought to market much before November, unless the demand for them is great and prices high. But from that time until the middle of February they are in fine marketable condition, and, being always left in the land where they grow, are lifted as required. Being thus left undisturbed, they preserve their flavour much better than they do when lifted and stored in pits.

BEETROOT.—A good crop of Beetroot is very remunerative, and when there is a ready sale for it in the market it pays better than any other root crop. The main sowing is made to succeed Wallflowers, Radishes, Spinach, or Cabbages, and it is also often grown on Asparagus ridges, between rows of fruit bushes, and between lines of Vegetable Marrows; and even when growing in the open field, it is often intercropped. An early sowing is usually made, in lines about 15 in. apart, in the first week of May between rows of Cabbages or Lettuces, recently planted; after the seeds germinate and the plants are well above ground, they are thinned out into patches with short hoes, and when they have formed a few rough leaves they are thinned out to single plants by hand. Some make a sowing even as early as in March in a sheltered piece of ground for yielding an early supply. In harvesting a crop of Beetroot which has to be kept through the winter, the roots are carefully dug up, preserving them their whole length intact, and keeping 2 in. of the stalks attached after the leaves have been twisted off by hand. They are then built in pyramidal-shaped clumps, and covered with straw, over which a coating of soil is put to exclude frost. Leaving the roots in the ground is the best plan, as their proper flavour is thereby preserved better than when lifted and stored; but they are liable to be injured by frosts in January, or to be locked in the soil when it might be convenient to send them to market. Some of the darkest and finest-shaped roots are kept for seed-bearing plants, and are planted in some out-of-the-way nook by themselves. Transplanting Beets is only resorted to to fill up vacancies in the rows, as in the operation the main roots are often broken, or otherwise so damaged, as to render it almost impossible for them to produce good roots. Dark crimson-coloured Beets are those which are most esteemed by market gardeners, most of whom grow their seeds saved from selected plants. Carters' St. Osyth is a favourite kind with many growers, but none are liked so well as the selected dark crimson.

CARROTS.—Early Carrots are largely supplied from France; they are very tender and delicious, and, in many instances, far better than those obtained from the London market gardens. The main crops of Carrots are treated in much the same way as other root crops. Seed of early varieties is sown from February to March, after which the main crop is put in, and the plants are not thinned out quite so much as other root crops. The Early Horn is the kind used for early sowings; and, when in good condition, they sell well in the market. There is a very handsome early Carrot named Early Nantes, which would make an excellent kind for market if it could be got true to name, but this is a difficult matter. The Long Surrey and Long Orange are the chief kinds grown for main crops, and roots of these are furnished by hundreds of tons

all through the winter months. Some growers force the Early Horn on hotbeds and in frames, in order to have them ready for use in March or April, and these realise good returns. Some also sow beds in a warm position in August and September for winter use. If the weather is mild, fine little roots are obtained, and they sell readily at good prices.

POTATOES.—In the neighbourhood of London early Potatoes are chiefly grown for market purposes, late kinds not being considered sufficiently remunerative to occupy such highly rented ground. The varieties usually cultivated are the old Ashleaf Kidney, Myatt's Ashleaf, Lapstone Kidney, and Regents. The ground selected for Potatoes, if an open quarter, is usually the lightest and driest at command, as in such soils the crop comes to maturity sooner than it otherwise would do, and tubers raised in such soils are of the best quality. About Deptford Potatoes are planted in rows 2 ft. apart, the ground being previously manured and trenched, and levelled down with the plough. Planting takes place as soon after the middle of February as time and convenience will permit. Some growers plant two rows of Potatoes between their lines of Gooseberry and Currant bushes, which are 6 ft. apart, and partially under the shade of large fruit trees; but when fruit bushes do not occupy this position, the Potatoes are planted in continuous rows, about 2½ ft. apart, just as they would be in open fields. Other market gardeners loosen the soil between the rows of their spring Cabbages in March with a steel fork, and therein plant Potato sets with a dibber. When the Potatoes appear above ground the Cabbages are removed for market; therefore, little or no injury happens to either crop, and as soon as the Potatoes get up a little and some earth is drawn to them with a hoe, the intervening space, if hard, is loosened with a fork, and again planted with Brussels Sprouts or early sprouting Broccoli. Before these can do much injury to the Potatoes the latter will be ripe, when they may be lifted at once for market, or kept for seed or home consumption. In cases in which Potatoes are grown in the open fields a crop of Lettuces may be got from between them, but after these are removed it is not considered well to plant anything else. No sooner are the tubers all lifted, than the haulm is collected and carted to the manure heap, and the ground is then manured, or not, according to circumstances, and ploughed or dug over, when it is ready for planting Cabbage, Coleworts, Leeks, or for sowing with winter Onions, Spinach, Radishes, Turnips, or late Celery. The summer culture of Potatoes in market gardens consists in hoeing and keeping the crop rigidly clean. Potato crops are always earthed up—an operation which is done by means of broad iron hoes or double-moulded horse ploughs; and they are, as a rule, lifted with forks, but sometimes by the plough, which performs the task more expeditiously. The tubers, being collected and sized, are put into bushel and half-bushel baskets, and are covered with haulm, which is held in its place by means of twigs of Hazel. These baskets are then piled one above the other in waggons for market.

With regard to general market Potatoes, a correspondent writing to the "Gardener's Chronicle" in the early part of 1878 remarked: When a grower of Potatoes for market can undertake to rent for a short season of six months land for the purpose of growing Potatoes for market at a charge of £13 per acre, it might well be asked, How are the profits to be obtained, and what kinds of crops are to be looked for? For this price the land is taken, well-manured and fairly well cultivated, the planter having the choice either of casting out drills with the plough or of dibbing the sets in. In the present case the former plan is adopted; the seed is laid in rapidly by women and boys, and plough-moulders follow behind and cover in as fast as the sets are laid. A wooden

roller presses down the apex of the ridges thus formed and presently harrows will be run over the ground, and this will leave it in excellent condition for hoeing when the crop is well through the ground. The average quantity of seed per acre is about 30 bushels of small and 35 bushels of large. The present average price of seed of Victorias is 5s. per bushel, which, exclusive of labour, adds to the expenses about £8, and if £6 be added for labour and general cost per acre for lifting and other charges, it will make a total of £27 per acre to be deducted from the value of the crop before there is any profit to go into the hands of the cultivator. Potatoes are a risky crop, late frosts may injure them, drought may check them, excessive moisture may provoke an undue amount of haulm growth and a severe attack of the inevitable disease. A good crop would be 8 tons per acre on ordinary fields and from that may be deducted ½ a ton of chits worth about 15s. for pigs' food, and 1½ ton of seed size, leaving 6 tons of ware for market. This estimate will only be fulfilled if there be no disease, but if, as is too often the case, one-third be diseased, the largest tubers as a rule being the worst, then at most there will be but 4 tons of ware tubers for market, and only 1 ton of seed. The price of Potatoes in the market is affected by the state of the crop, which, because of the immense extent of ground planted, is certain to be an abundant one if there be no disease, and the price then will range from £4 to £5 per ton. With a clean crop of Victorias held over until the market had settled down to its winter price at £5 per ton the amount realised per acre for 7½ tons would be £37 10s., and adding 15s. for the ½ ton of chits, £38 5s. A diseased year would give 5 tons at about £9 per ton, which would give a total of £45 15s.—a better paying crop, though less in bulk; but as the disease is so irregular in its effects it may be that this particular grower would not have more than one-half a crop clean for sale—a common result when the disease is very prevalent, and therefore it would not be safe to look in any case for a product that should realise more than £40 per acre under any circumstances. If from this be deducted the £27 per acre for expenses, and at least £3 for cartage to market, it will be found that £10 per acre is no great profit to look for out of such a venture, as all the amount deducted must be paid in hard cash before the crop can be marketed. In spite of all the contingent losses to which the cultivation of the Potato for market is liable, it is evident that it is in market districts yet one of the most wide-grown and best paying crops. During the present winter, whilst Turnips have been selling for a song and green stuff could hardly be given away, good Potatoes have been fetching £10 per ton, and to have more of a vegetable that will certainly sell at a good price is the desire of all growers. Even so late as the end of March is comparatively early for the planting of Potatoes in the open field, but Victorias are late growers, and therefore the safest to plant now. The more growers on a large scale recognise the desirability of planting the latest sorts first and earliest kinds last, the more probable is it that their crops will escape at least one of the Potato ills—late spring frosts.

TURNIPS.—Generally speaking, the Turnip is not considered to be a very profitable crop; the demand for it in summer is not great, but in winter and spring large quantities of Turnips are disposed of, and the tops or greens from the winter crop fetch good prices in spring, especially when other kinds of greens are scarce. They are usually sold by the pound or bunch. The earliest sowing of Turnips is made in the end of January or early in February, in pits or frames, or on hotbeds without frames; and main sowings are made broadcast on a field about the end of February, or in March, to be succeeded by another sowing made in April. After the plants come up they are thinned, and the surface-soil is at the same time

loosened by means of small hoes. The largest roots are first drawn for market; thus the plants get thinned, and those that remain have more space for development. The Early White Dutch is the variety commonly used for spring work, and the White Stone for main crops. When grown in brick pits, 2 ft. or 3 ft. of rough fermenting material is cast into the pit and firmly trodden down, and on this is placed a few inches in thickness of garden soil, which is also made firm. The seeds are then sown broadcast, and afterwards the frame is kept close and moist until germination has taken place, when plenty of air is admitted on every favourable opportunity. If the seedlings come up too thickly, they are thinned out to 3 in. or 4 in. apart. Frame Turnips are never large; the aim is to grow them quickly to the size of a hen's egg, when they are tender and of good flavour, and to market them at once. The method of growing them in hotbeds without frames is, to cast out trenches 18 in. deep, 6 ft. wide, and of any length, and firmly fill them with manure; over this a coating of soil is placed, and rolled or beaten solidly with the back of a spade; the seed is then sown, slightly covered, and finished off by rolling again; hoops made of Hazel sticks are then fixed over the beds, so that they can be covered with mats, and in the event of hard frosty weather setting in, some straw litter is added to the covering. If the weather is mild, the mats are let down every day so as to admit light to the young plants; and as soon as it can be done with safety, they are removed from over the beds and left erect around their sides in order to ward off winds. Sometimes the aid of either frames, or hoops and mats is dispensed with, and the crop is grown on hotbeds like those just described, a little loose litter being merely strewn over the surface until the plants are established; in this way excellent Turnips are produced a week or two later than those which have been protected. Some growers use the space between the lines of frames for growing Turnips; and well it answers for that purpose, as, owing to the soil being below the general level, it keeps comparatively moist, and the belts of frames protect the plants considerably. The soil between Turnips is kept stirred with the hoe as frequently as possible, for no crop is more benefited by surface-stirrings than this. Early Snowball is a kind sometimes used for main crops, and also a very hardy variety named Six Weeks. The Chirk Castle Black Turnip is often seen in winter in the market. It is the hardest Turnip grown, and although its skin is quite black, its flesh is as white as snow, and of excellent quality. Spring Turnips are generally got off the ground in time to permit of it being cropped with French Beans, Summer Cabbage, Spinach, or Celery. Turnips for autumn use, and also the winter ones, however, consist chiefly of the White Stone, which is a beautiful white-rooted sort, which cultivators generally sow on ground just cleared of Peas, and send them to market in winter.

JERUSALEM ARTICHOKES.—These find but little favour with the London public, and there is but little demand for them; consequently, they are not grown in London market gardens. As this vegetable may be grown in almost any place, it is generally planted on gravelly pieces of ground that would be too dry for other crops. Knolls or mounds are usually cropped with it, and it is also grown along the sides of hedges and in shady places. A few growers, however, grow it on good soil in open and somewhat exposed positions, and the result is an abundant crop of fine tubers. After preparing the ground by manuring and digging or trenching it, the tubers are planted in February, in rows like Potatoes, and are allowed to grow unchecked, and without being earthed up, till November. By this time they will be ripe and in good marketable condition. The stems, which are sometimes killed by the frost, are cut over close to the ground, and earth is spread over the

tubers to exclude frost. The tubers are lifted for market as required, as their flavour is better when so treated than when lifted and stored in pits. In February all that remain are lifted, for if left longer they would be useless for culinary purposes; what are required for sets are then saved for that purpose and the remainder sold for what they will fetch.

SALSIFY AND SCORZONERA.—These, though not popular market vegetables, are grown in limited quantities in some of the best market gardens. The seed is sown rather thinly early in April, in drills about 1 ft. apart in deep rich soil. When up the plants are thinned to 6 in. apart in the rows, and during their early stage some catch crop is planted between the rows. The roots are generally left in the ground till they are wanted for market, when they are lifted carefully so as not to break the roots, which in that case would lose their milky juice, and consequently their flavour.

HORSERADISH.—This is not grown to a very great extent in London market gardens, but where it is found in them it is always in deep, rich, open soil. Crowns such as are not marketable are planted deeply in trenches 2 ft. apart; the plants stand 1 ft. asunder in the row. Manure is then applied on and about the crowns, which lie in a slanting position in the bottom of the trench, and they are at first not deeply buried. Early in spring, after they have started fairly into growth, the ridges between the trenches are levelled down lightly, and a crop of Radishes is sown on the surface, the latter being off in May, and by the time the Horseradish appears in full row, the Radishes are cleared off the ground, which is hoed and afterwards kept clean. Covent Garden is, however, now chiefly supplied with Horseradish from Holland. A few weeks before Christmas may be seen on market mornings huge heaps of it, consisting of bundles containing from 20 to 25 sticks each, of first-rate quality, tied up with small, but strong withes. These bundles arrive packed firmly in casks, each of which holds nearly 300 bundles. The sticks are not washed before being packed, but are placed in the barrels apparently as they are dug up, with a quantity of soil adhering to them, and in this way they keep good for a length of time. December being the principal month in which Horseradish is required, it would scarcely answer the purpose of market growers near London, who have to pay high rents, to occupy a very large portion of their ground with crops that will not admit of others being grown between them, and which can only be sown in quantity at one particular season.

C. W. S.

Children's Gardens.—Allow me to say that the love of flowers is not wholly confined to the educated. The poorest children enjoy their Saturday's holiday searching for the early Primrose, Violet, wild Rose, or Honeysuckle just as much as those of the rich; nor do I for a moment think that all collect their flowers for the sake of the penny which the squire's or parson's wife gives them. I may remark that the cultivation of the soil is one of the greatest blessings conferred on us. What is the first thing which the agricultural labourer, returning from his toil, wants to see after supper? It is his garden. He feels no longer fatigued by labour, his helpmate forgets the worry of domestic duties that needs must be, and his children forget that awful School Board. See the so-called gardens of poor children in the environs of London; a little Mustard and Cress, a few stunted Radishes, a stray Wallflower, a little London Pride, a Daisy, yet these are a source of the greatest interest. Turn, then, to older children. How many of the hard-working men on our railways could bear their dreadful solitude as pointsmen unless they had some ground, perhaps unfruitful, to tend? How many weary hours are there in that waste spot wiled away? How many cares forgotten, troubles lightened, offences forgiven? I speak as a gardener, though but an amateur; yet to live in any town for a lengthened period is wearisome. I must have my Roses and even my Cabbages to look at.—EUGENE E. P. LEOG, M.A., *Court House, Linton Cheney, Dorset.*

THE INDOOR GARDEN.

ADIANTUM PALMATUM.

THIS handsome and distinct species will make an excellent companion to *A. Farleyense*, owing to the large size of its pinnae and the length of its fronds. It was discovered by M. Roelz, at an altitude varying from 10,000 ft. to 11,000 ft., in Peru, a fact of great importance, as it may be cultivated in a greenhouse temperature. A very noticeable feature in the plant is the flexuose or zigzag character of the rachides, most marked near the apex of the fronds and the rachides of the primary pinnae. The pinnules are herbaceous in texture, smooth, large, from 1 in. to 1½ in. in breadth, distant and very distinctly stalked, the stalks varying from ¼ in. to ⅓ in.; the terminal ones are usually wedge-shaped, while the lateral ones are truncate at the base, so as to become semi-circular in outline; they

is nothing better for shading than scrim canvas, which may be obtained of almost any draper. Pieces should be cut off about 4 ft. in width and the length of the light, and each end should be tacked to a light wooden roller. Thus arranged, they may be used with facility, and they do not get displaced by wind.—J. C. B.

THE FRUIT GARDEN.

INSECTS ON FRUIT TREES.

THE unseasonably cold weather which we have experienced for a long time past has not only been injurious to the blossoms of all fruit trees, but, owing to their slow rate of growth, has rendered them a prey to insect pests, and more especially to green fly, with which

Adiantum palmatum.

are deeply cut down into from three to five large lobes, which are again more or less parted, an oblong sorus terminating each of the divisions in the fertile portions. It received a first-class certificate when shown some time ago at South Kensington. For the annexed representation of it we are indebted to Mr. Williams, of Holloway.

Shading Frames.—Shading of some kind for frames is necessary during the summer months. Bast mats are often employed for that purpose, but the shade which they afford is far too dense for most plants. The light which plants growing in frames receive is never equal in value or in power to that admitted into houses, hence the necessity for using some material which merely breaks the force of the sun's rays without depriving the plants of their beneficial influence. Perpetual shading by means of whitewash is not advisable; it may save labour and guarantee the foliage against scorching, but the little extra labour involved in putting on and taking off shading material will be recompensed by the extra vigour of the plants. There

Peaches and Nectarines are now in most places badly infested. In fine, warm seasons these are easily dealt with, as then one need have no hesitation in using the garden engine and freely wetting the foliage, but to do so while we have no sun, and with a cold, biting wind always blowing would only make matters worse, as although the fly might be washed off or destroyed, the wet would be productive of much harm. Vegetation will stand a great amount of cold so long as the atmosphere surrounding it is dry, and, tender as the young leaves of Peaches and Nectarines are, they form no exception to the rule; therefore during such times as these every effort should be used to screen them from damp as much as possible, as under such adverse circumstances nothing is so fatal to the flowers. Rather than syringe or wet the trees thus early under the present unsettled state of the weather, it will be advisable to go carefully over them with Tobacco dust, which, puffed among the young shoots by means of a cheap, handy distributor, now made and sold for the purpose, will soon destroy the fly. A shilling tin of Tobacco dust used judiciously will go a long way if applied during a still day, as otherwise there is much waste, owing to its being very light, and

therefore easily blown away. As this ground Tobacco lodges in every curled leaf and on the tips of the tender growth, it soon makes these positions very uncomfortable for insects, and the more they disturb themselves the more enveloped they become, till death puts an end to their struggles. In order to cleanse the trees when the weather gets more favourable wash off any stragglers that may have escaped; there is nothing better than a well-directed stream from the garden engine; but as the foliage is this season thin and easily torn, the jet should be broken, and not allowed to play against it with full force, unless at a long distance off, so as to diminish its power. In order to give the trees and wall time for drying, this operation should be done early in the morning on a warm, sunny day, but by-and-by the evening is the proper time for such work, as then it has a very refreshing effect and prevents the spread of red spider, a pest to which Peaches and Nectarines are particularly subject. Fortunately, however, they cannot endure cold water, which not only keeps them moving, but breaks up their webs.

It is the practice with some to use one or other of the many kinds of insecticides made for the destruction of red spider and green fly, but if not very carefully applied and properly diluted they are dangerous, and often do considerable harm to the fruit. For use in a liquid form there is nothing so safe and effectual as Tobacco juice, obtained by steeping the Tobacco in boiling water, and adding thereto an ounce of soft soap to every gallon, and if some Quassia chips be soaked or boiled with it the mixture will be all the more effectual. A pound of Tobacco added to the ingredients just named is sufficient to make 10 or 12 gallons of a strength that will kill green fly almost directly it touches it. A decoction made as above stated is always handy to keep in a large bottle for the purpose of dipping fruit tree shoots into, and also those of Roses, for it frequently happens that if taken in time the spread of these insects may be stopped at once, and much after-labour and annoyance saved.

I have found that Peach and Nectarine trees growing on walls derive much benefit from being syringed with soap-suds every week or so, followed daily with clean water; the suds act as a preventive, which, as the old proverb says, is better than cure. Certain it is they act as a charm, and in some way or other have a very stimulating effect, for whenever used the foliage soon assumes a changed look for the better, and remains in a healthy condition. Apricots, though not subject to green fly or red spider, are very liable to the attacks of a maggot that curls up the leaves and eats its way out. These are unusually plentiful this year, and should be searched for and destroyed, or they soon do irreparable mischief.

The Gooseberry caterpillar is one of the most annoying and destructive of insects, as it is so voracious that it clears all before it, that is, so far as leaves are concerned. Many resort to picking it off by hand, but the quickest way to exterminate it is either to dust the bushes with Hellebore powder, or syringe them with a decoction made from steeping leaves of the common Foxglove in water. In order to deal with the aphid on Currants the best way is to snip off the tops of the young shoots, as it is only the tender leaves there situated that they attack.

S. D.

QUALITY OF STRAWBERRIES GROWN FOR MARKET.

"J. S. W.'s" statement (p. 373), that it does not pay market growers to ripen their Strawberries properly, and that they "hurry them into market as soon as they are red, whether ripe or not," will probably astonish those who, like myself, know from long experience that the very reverse of these conditions is necessary in order to make Strawberry forcing profitable. Allow me, as a market grower, to inform "J. S. W." that it does pay not only to ripen Strawberries, but to finish them off in a perfect manner; but it certainly does not pay to send unripe fruit into the market. If "J. S. W." had sent as many baskets of Strawberries into Covent Garden Market as I have done, he would be aware that it is the high finish, that is to say, the fine glaze, combined with size and flavour, which regulates the price. So much is this the case, that of a given variety, some samples, although equal in size, will not realise so much by several shillings per pound as others which are better finished off; not only is this the case, but the experienced grower knows full well that by gathering his fruit before it is matured, it loses considerably in weight. Your correspondent has probably confused the outdoor Strawberry with the forced fruit, the former, owing to various reasons, being gathered as soon as it is coloured; but the best growers allow their forced fruit to hang until it is ripe, knowing from long experience that such is the only way to make the most of their crop; they thereby ensure both quantity and quality. No market grower would prefer to send sour Grapes, immature Pines, or Melons, or half-ripe Peaches to market, and yet "J. S. W." asks us to believe that such growers are so little

alive to their own interests as to gather their Strawberries before they have attained either their proper weight or flavour. "J. S. W." does not appear to be aware that the market is subject to constant fluctuations. So much is this the case, that growers, instead of always picking their fruit before it is ripe, are often at great pains to keep it for a time until there is a demand for it. It will probably surprise "J. S. W." to hear that we have often had here during the middle and latter end of May upwards of 2 cwt. of fruit hanging ripe for a week before it was gathered. There is no regular price for fruit, its value being regulated entirely by the demand, which often fluctuates in a remarkable manner. Regular growers for market are fully aware of these changes. I am acquainted with a very large grower, the largest, in fact, in the neighbourhood of London, who has at the latter end of May the whole of his houses full of ripe Strawberries. On one occasion I was there when every fruit in the place was ripe, and the whole of the glass was heavily shaded, the grower in question informing me that he dared not water a single plant. This was at Whitsuntide, when good fruit is seldom wanted, and, I may add, that a few days later the price advanced, when, of course, the fruit was immediately marketed. "J. S. W." will therefore perceive that he has been wrongly informed.

As illustrating the influence which flavour exercises upon the value of Strawberries, I may mention that the variety *Marguerite*, which, although when well grown, is in appearance scarcely inferior to Sir C. Napier and grows much larger, never realises so much as the last-named variety, the reason assigned by the fruiterers being that their customers complain of want of flavour. I will cite another instance which should convince "J. S. W." that flavour is held to be of the first importance in a market Strawberry. Some years ago I crossed *Marguerite* with Sir C. Napier, hoping to secure the fine qualities of the latter in connection with the more robust habit and enduring nature of the former. I obtained some really handsome-looking varieties, large and firm, with a beautiful glaze, in fact, the very perfection in appearance of market Strawberries. I took them to a leading fruiterer in the Centre Row, Covent Garden, who was pleased with their appearance, but, on tasting them, he at once emphatically condemned them, as they all, unfortunately, in the way of flavour resembled the female parent. When *Vicomtesse Héricart de Thury* first came into notice I asked the opinion of this same fruiterer concerning it. His words were: "It is of no use to you; do not grow it. It is bright, but deficient in flavour," and yet the same man stands ready to buy almost any amount of good Napiers.

When I said that market gardeners were obliged to grow kinds possessing a more delicate constitution than *Héricart de Thury*, I simply stated a fact "J. S. W." corroborates himself, as he informs us, and quite rightly, that Sir C. Napier is the kind most extensively grown by them, but he should have added that, owing to its flimsy, tender character, it is one of the most difficult kinds to manage. "J. S. W." may rest assured that, were *Héricart de Thury* equal in quality to Sir C. Napier, and that did it realise the praise which that variety does, market growers would be only too glad to adopt it on account of its accommodating nature. And yet "J. S. W." informs us that private growers who force *Héricart de Thury* grow first-rate sorts, but that market growers, who almost confine themselves to Sir C. Napier, only grow second-rate kinds. An effective illustration of the relative value of the two kinds will be found in the fact that a grower here, who was induced to try *Héricart de Thury*, only realised for it the half of that which he obtained for Sir Charles. It will therefore be seen that, commercially, the latter kind is first-rate, whilst the former is barely second-rate. *Héricart de Thury* is simply a good hardy kind, well adapted for early forcing, as it sets freely.

The fact of "J. S. W." having seen badly-grown Strawberries in Covent Garden does not prove that the bulk of the fruit sent there is inferior. Some of the worst samples I ever saw for sale were from private establishments, and yet I should be sorry to assert that private growers, as a rule, do not know how to grow Strawberries. A moment's reflection must suffice to convince "J. S. W." that he has entirely reversed the order of things, and that the best Strawberries are more likely to be furnished by those who devote their whole time and resources to this branch of fruit culture than by growers in private establishments. I am acquainted with one market garden in which nothing but forced Strawberries are grown in the glass structures. For forty years has this industry been carried on there, and your readers may believe me when I state that the quality of the fruit grown in that establishment cannot well be surpassed. If "J. S. W." wishes to be classed amongst those who grow first-rate sorts, he has been unfortunate in selecting such kinds as *Héricart de Thury* and *Black Prince*; the latter variety scarcely pays for the labour of watering. Let me recommend "J. S. W." to substitute for them *Keen's Seedling*, *President*, *Alice Mande*, or Sir C. Napier, kinds which may not be so easy to grow, but which, when well-ripened, are highly flavoured. With respect to the last-named variety,

from the old stools of list 3, which will be planted in the same pit as soon as it is ready.

4.—A Pine pit planted with rootless suckers on February 7, 1878, produced the following results, the first fruit being cut on July 6, and the rest in succession:—

Date.	No.	lb.	Date.	No.	lb.	Date.	No.	lb.

The pit in which these were grown is of the same dimensions as the other, and contained the same number of plants; four fruits in it did not ripen, and one plant did not start. The list is merely given to show what can be done in twelve months. M.

Artificial Heat for Vine Borders.—"As proof," says "S. D." (p. 373) "that good Grapes may be grown without artificial heat, I send you a couple of leaves!" I would respectfully submit that fruit is in question, not leaves, and if your correspondent wished to prove that early Grapes could be grown to perfection without protected borders, I think, in common reasonableness, he ought to have sent you fruit as well as leaves, even though it is now getting well on for midsummer, and explained as well if his Vines were planted inside or outside, and other necessary particulars. If leaves are reckoned "proof" of a crop of fruit, I claim to have beaten your correspondent, and, in confirmation thereof, send a sample of leaf, 16 in. by 16 in., from Black Hamburg Vines that are now stoning their berries, and which have for years been treated with fermenting materials. I have often, indeed, had leaves nearly 18 in. each way, and the colour and texture, as will be seen, is not amiss.—J. S. W. [The leaf sent fully bears out all that "J. S. W." asserts in reference to this matter.]

EFFECT OF LOCAL INFLUENCES ON GARDEN CULTURE.

A FEW years ago my plant houses were affected for a season similarly to those of "E. T." (p. 356). Everything sickened and turned yellow, and as I had made no change, except as regards the water, to that my gardener attributed the disaster. Owing to a droughty summer, he was obliged to have recourse to the water company's supply, which contained bi-carbonate and sulphate of lime in solution in considerable quantity. Whether it was these impurities, or the fact of the water being applied to the plants often direct from the mains, and consequently below the temperature of the houses, or both, that induced ill health I cannot tell, but on providing a larger store tank for rain water the plants soon began to recover themselves; it took however, a second season before the effects passed off completely, especially as regards Camellias and Azaleas. I may state that my garden was within 3 miles of a manufacturing town of 200,000 inhabitants, and in one of the largest chemical and lead-producing districts of the kingdom; nevertheless, we had no difficulty in getting very satisfactory results in plant culture, with the just-named exception.—T. B.

—In compliance with the request for further particulars of some of your correspondents, who have kindly replied to my previous letter (p. 386), I may state that the garden is situated about half way between Birmingham and Leamington, on rather high ground with a heavy clay subsoil, and is exposed to the south-west wind; the air of the district is very pure. I think it may be assumed that defective ventilation is not the cause of the mischief, nor fumes from paint, &c., which could scarcely permanently affect Chrysanthemums grown under glass only when young. Excepting a trial of Carson's paint on one range, the best lead paints only have been used. Some of the houses have been built fifteen years, but the deficient growth was first noticed in

the Chrysanthemums about seven years ago, since which time the number of affected plants has gradually increased up to the present time. The influence shows itself in arrested growth of the foliage, which, I think, is the part first affected, for upon examination the roots generally appear to be healthy, though in turn the imperfect development of the leaves re-acts on the roots, and their growth is arrested. Then the deficiency of root action renders the soil stagnant, and the utmost care has to be exercised to avoid making matters worse by untimely watering. The plant does not die, but languishes in a weakly condition favourable to the attack of insects. Newly potted plants are slow in starting, and newly purchased plants are difficult to establish. No fungoid growth is observable, and although I have not examined the tissues microscopically, my knowledge of the microscope leads me to think that its ordinary powers would not reveal the cause of the disturbance; however, I will make the suggested examination. I fear chemical analysis of the soil will be of little use, for having tried many soils from various districts with the same results, it can scarcely be a question of the relation of its inorganic compounds, and organic matter is difficult to discriminate; if anything organic be the cause, from the peculiarities of the case, it must be assumed to be a local infection; the separation of this from the other components of the soil would be beyond the powers of the most accomplished chemist. At one time the only admissible explanation seemed to be the wilful or negligent mixing with the compost or water of some deleterious matter; but, after careful examinations and many precautions, I concluded that the idea had no foundation. Noxious fumes from factories must be so diluted, if they reach one at all, as to be inert; besides, plants grow quite satisfactorily in the immediate neighbourhood of Birmingham, which emits the most varied fumes, and is in close proximity to the Black Country. I fear even the good gardener, whose observations have been limited to the ordinary results of efficient and deficient cultivation may not possess the special knowledge necessary to enable him to elucidate the mystery; my only hope is that some one who has had a similar experience may be able to give an explanation.—EDMUND TONKS, Packwood.

—Mr. C. W. Quin is surely wrong in blaming our Warwickshire manufacturers for "E. T.'s" failures. He ought to come to Birmingham and see the collection of plants in our Botanic Garden; also the Primulas grown by Mr. Tomkins, and his Maréchal Niel Rose tree with hundreds of bloom on it—both places within a mile or so of various chemical and other works, and quite near a forest of chimneys. All around this smoky town, too, are numbers of amateurs who grow plants of a very delicate kind very successfully.—F. BANKS, 149, Warstone Lane, Birmingham.

—Theoretical knowledge, such as that which "E. T." states he possesses, is almost invariably fatal to success when not accompanied by practical experience. It is only by means of sound knowledge as regards the routine of cultivation that the operator is enabled to know how far to go and when to stop in shaping his practice in accordance with theoretical deductions. "E. T." requires no further answer than the advice given by "Chef" and "J. M." If he already has, or will get, an intelligent, experienced gardener, and tell him fully and exactly what he requires, allow fair means for carrying out the work, and patiently await results, giving a kindly word of encouragement to try again in cases of failure, I have no doubt that he will very soon see an improvement in his garden such as will surprise and satisfy him. Mr. Quin's conjectures as to the cause of "E. T.'s" failures will not bear the test of a moment's reflection by any one who has ever seen and noted the innumerable examples of successful gardening in the case of a large number of the usually cultivated plants in close proximity to the manufacturing districts, and still less by any one who, like myself, has lived and been engaged for over twenty years within ten miles of Manchester, and for some half-dozen years of the time between that smoke-begrimed city and Stockport, where the wind, when blowing from three out of the four points of the compass, is laden with smoke and noxious gases arising from a variety of manufactories. Soil and air combined make the cultivation of many kinds of plants out-of-doors in this and similar places an impossibility, but not so such as are grown under glass, although even with the latter it is uphill work, inasmuch as everything requires great labour and attention, if only to keep their leaves washed and the glass clear from soot accumulations. Within half-a-dozen miles of Manchester there can be seen collections of Orchids, hard-wooded stone and green-house plants, Azaleas, and Heaths, together with Fuchsias, Pelargoniums, and hundreds of other plants not surpassed, if even equalled, by any in the kingdom; the same, too, holds good with culinary vegetables and fruits grown under glass. This is so well known by all connected with horticulture who move about the country as not to need mentioning, and no more instructive lesson in gardening can well be learned than is derivable from a ramble through the collection of plants grown in the Manchester district. From an intimate

acquaintance with the neighbourhood, I feel convinced there is not anywhere to be seen more conclusive evidence of the inherent love of gardening existent in human nature than is here exemplified both amongst employers and gardeners. The results of gardening around this great manufacturing centre have a direct bearing upon the case, which has given rise to these remarks in showing what it is possible to accomplish where there is union of feeling and a perfect understanding between employers and their gardeners, without which there can never be very much accomplished, either satisfactory to the former or that will reflect credit upon the ability of the latter.—T. BAINES.

MESSRS. J. B. BROWN & Co.'s price list, just received, contains illustrations of wrought iron hurdles, bar iron and wire fencing, carriage entrance and wicket gates, galvanized wire netting, seed and

Galvanized Wire Strawberry Guard.

Strawberry guards, Pea supports, French system of iron and wire fruit trellises, wiring for garden walls, wrought iron tree guards, lawn mowers, garden engines, rollers, pumps, lawn seats, cast iron

Galvanized Wire Pea Trellis.

vases, and many other garden appliances. It also contains an eyed straining trellis screw, with nut for tightening French trellis work, said to be better than the radeisseur. The list is excellently printed and has many engravings, far more delicately done than those which usually embellish catalogues.

PROPAGATING.

FERTILISING FLOWERS OF THE CHINESE PRIMROSE.—It is a curious fact in relation to all the members of the Primula family, whether tender or hardy, or from whatever clime they may come, that most of the flowers are pin-eyed, that is, have the stigma projecting beyond the pollen anthers, and in many cases even beyond the throat of the flower. This feature is less marked, or indeed entirely absent, in show Auriculas and Polyanthus; but these have been selected during many years' careful watching from myriads of seedlings, three-fourths of which were pin-eyed. If seed of these be saved from high-class thrum-eyed flowers, the results just indicated will inevitably follow. This is a fact at once curious and inexplicable but for the probable reason that there is a tendency in all newly-raised florists' flowers to revert to the original wild form in which the pin-eye is invariably green. It is a moot point whether the pin-eyed flower forms the best seed parent if left to Nature's operations or not, but in the Chinese Primrose the majority of plants produce pin-eyed flowers, although in this case the defect, if it be one, is much less noticeable than is the case with Auriculas and with the Polyanthus. As with the Chinese Primula it is absolutely necessary that it be annually raised from seed, so is the production of seed of the greatest moment. Those who make seed growing a speciality find that it is necessary during the winter months to use a small camel-hair brush freely, to bring the pollen from the stamen to the stigma, and thus promote fertilisation. The late Mr. Windebank, of Southampton, who used to have a collection of some twelve or fourteen kinds, always employed a different brush for each sort, in order to secure distinctness, and he was most successful. Others adopt the

practice of pulling the flowers, so that the pollen may be deposited on the stigma in its upward passage—a doubtful remedy, as the pollen is more likely to be retained on the under side of the stigma than on its pin-head surface. Where bees can get at the flowers they will fertilise them freely, but the best results are got from thrum-eyed flowers, in which the stigma is placed just below the anthers, and where some of the pollen is sure to fall upon it. It is absolutely necessary that the atmosphere should be fairly dry during the period of fertilisation, otherwise the pollen will be of no value. A. D.

ANSWERS TO CORRESPONDENTS.

Syringing Vines.—Ought Vines to be syringed with water from now until the fruit begins to change colour? or had the house better be kept quite dry, and merely the Vines roots outside moistened by watering the border? The hunches are just showing. No heat is used except a fire at night to prevent damage from frost. My Vines suffered badly from mildew two years ago, which killed every berry, and last year the crop was small.—J. H. W. [If you keep the floors and walls of the Vinery moist you need not syringe the Vines themselves. Much has been said in favour of syringing Vines, much against it, but all that has yet been arrived at is that equally good Grapes can be produced either way. As, however, your Vines are subject to mildew, merely keeping the floors moist will suffice, and this must be discontinued on the first appearance of that fungus. Ventilate freely, avoiding draughts, leave no more foliage than can be exposed to light, and regulate the crop according to the amount of foliage. A little fire-heat at night will do good, as then you can leave on a little air at top. As soon as you discover mildew paint the hot water pipes with sulphur, and at once remove affected leaves or berries.—S.]

Outdoor Camellias.—Kindly name a few of the handsomest of hardy Camellias, and also say whether or not Lady Hume's Blush is suitable for outdoor culture.—C. B. [Nearly every kind of Camellia will succeed out-of-doors under favourable circumstances. Lady Hume's Blush is one of the best which could be used for that purpose; other kinds might consist of the old Double White (alba-plena), Beall's Donchleari, imbricaria (red), Marchioness of Exeter, Reine des Fleurs, and Wilderi.—CAMBRIAN.]

Greendey on Roses.—What are the best means of destroying the small green fly which infests Roses? I tried strong Tobacco water last year and constant brushing off with a white feather, and could not get rid of countless numbers of these pests.—H. S. G. [First wash the insects off as far as possible with cold water applied with force by means of a good syringe. Then, again, use a very strong solution of Quassia chips, boiled in soft water, at the rate of 4 oz. to the gallon, in which may also be dissolved 4 oz. of soft soap. The ends of the shoots most affected may also be dipped in this solution.]

Herbaceous Calceolarias.—We have at present a fine show of these in our conservatory, they have been very well treated, but, at least, as far as we are concerned, as we have had them well in flower for three weeks, and they promise to finish their three months of bloom. The plants vary from 1 ft. to 1½ ft. in height, and measure some 2 ft. across. I send you some blooms of them for inspection.—M. G. [The blooms sent are large, finely spotted, and good in form—altogether what would be called a good strain.]

Saxifraga flagellaris.—In "Notes from Kew" (p. 329) I see mention made of a plant with this name. I have never met with the plant, and I am sure that it must be scarce. Does it differ from *S. arachnoides* described by Haworth?—T. ROS. WILLIAMS. The plant in question is the true *S. flagellaris*, of Kew. Though as yet rare in cultivation, it has, however, been grown at Kew for some years. It comes from Arctic North America.—W.]

Rose Petals.—Are these saleable anywhere in London?—A. B. [Freshly-gathered petals of fragrant Roses like the old Cabbage, in quantities of 1 cwt. or more, are bought by wholesale druggists and also by the herbalists in Covent Garden, but Rose petals when dropping have lost their fragrance and are of no value.—P.]

Salisfly Seeds.—Will these grow the second season?—MAGNUM BONTUM. [Yes, if they have been kept airtight, and were good in the first place, but we should prefer fresh seeds.]

Rose Celeste.—"C. R." (p. 369) inquires triumphantly who cultivates this Rose? Allow me to inform him that I do, and that I have done so for years. This old Rose is a most determined coloniser, and hard to extirpate, should any one be so ruthlessly inclined. "C. R." has tolerably well described it, and I may add that in the bud it is a very jewel among Roses.—THOMAS WILLIAMS, Ormskirk.

Camellias in Orchard Houses.—We have a large double white Camellia planted in a cool orchard house which is only heated sufficiently to keep out the frost. The tree is very healthy, and is every season covered with buds, but the young wood is made before the buds open, and when the young shoots are out the buds have all swollen to the size of Walnuts, they mostly fall off and very few come to perfection. It is planted in a good light near the glass, and receives plenty of water. Would it do better taken up and potted so that it might have more heat? If so, at what time should that be done? or can the tree be treated in any other way?—M. A. E. [The case of the Camellia in question not flowering is probably due to its being placed in a too warm position and watered too freely just before the expansion of the flower buds, thus prematurely exciting the leaf buds into growth. Try cool and airy treatment, and give it less water till after the flowers have fallen.—W.]

Names of Plants. *R. H.*—1, *Frutillaria Meleagris* alba; 2, *Tenocym pulchellum*. *M. R.*—Double variety of *Anemone coronaria*. *W. C.*—Red de Chatenay Violet. *W. D.*—*Sonchus pinnatus*. *W. C.*—*Omphalodes verna*. *H. & Co.*—*Anemone nemoralis* l-pl. *X. Y. Z.*—*Amelanchier canadensis*. *F. H.*—*Saxifraga cespitosa*. *W. C.*—*Eupatorium ageratoides*. *W. M. S.*—1, *Brassia verrucosa*; 2, *B. maculata*.

Questions.

Vicomtesse Hericart de Thury Strawberry.—Not being sure as to having the true variety of this, and wishing much to get up a good one of the right kind for forcing, I should be glad if some of your correspondents will kindly state what are its distinguishing features. Those I have retain the petals till the fruit is far advanced, and to one's thinking would burn out indifferent settlers, as the anthers appear bare of pollen and are not pushed out well over the fruit.—S.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

MAY 13.

THE exhibits at this meeting, though not very numerous, and consisting chiefly of miscellaneous groups, contained many plants of great interest, both as regards rarity and novelty. The numerous and choice collections of Messrs. Veitch & Sons, B. S. Williams, and others, the superb cut blooms of Roses from the Waltham Cross and Cheshunt Nurseries, Mr. Dean's Primulas, and the Daffodils from Messrs. Barr & Sugden formed leading features, which were much admired on account of their general excellence.

First-class Certificates were awarded to the following plants:—

Ranunculus Lyalli (Veitch).—A beautiful and rare New Zealand Crowfoot, having peltate root leaves of a leathery texture, and flower-stems of about 1 ft. high, branching and bearing flowers $2\frac{1}{2}$ in. across, saucer-shaped and pure white, with a central tuft of golden-yellow stamens.

Arnebia echioides (Elwes).—A rare and very handsome, perfectly hardy Boragewort, from Asia Minor, with lance-shaped root-leaves, and dense clusters of funnel-shaped flowers $\frac{3}{4}$ in. across, bright yellow, with a black spot between each division of the corolla, gradually fading to pale brown, and at length becoming quite obliterated.

Primula acaulis Golden Gem (Osborn).—A pretty variety of the common Primrose, with flowers of a much darker shade, and borne very freely.

Polyanthus Prince of Orange (Dean).—A very bright yellow-coloured and free-flowering kind of the Hose-in-Hose type.

Begonia Comtesse de Choiseul (Laing).—A fine double-flowered variety with delicate bluish-tinted blossoms of fine form.

Azalea mollis var. Comte de Gomer (Veitch).—A pretty variety and an abundant bloomer, the flowers being produced in large clusters, and of a rich salmon colour.

Dracena superba (Williams).—An elegant hybrid of graceful habit with rather narrow leaves, the lower ones of a deep metallic lustre, the upper of a rich magenta tint.

Croton Princess of Wales (Veitch).—An extremely ornamental variety with narrow spirally-twisted and gracefully arching leaves from 1 ft. to $1\frac{1}{2}$ ft. long, beautifully variegated with creamy-yellow and various shades of green.

Amaryllis Mrs. Morgan (Williams).—A superb variety with large blossoms of fine form, of a deep rich crimson colour, margined with pure white.

Cupania elegantissima (Williams).—A fine decorative plant with pinnate leaves, resembling many of the Cycads.

Azalea pontica var. narcissiflora (Veitch).—A handsome yellow-flowered novelty aptly named, as its long tubular blossoms, widened at the mouth, strikingly resemble the flowers of several of the large kinds of Daffodils.

Selaginella Kraussiana aurea (Donaldson).—A golden-leaved form of this well-known kind, and one very desirable for the sake of variety.

Miscellaneous Groups.—Messrs. Veitch & Sons staged an effective mixed group of plants, to which a silver-gilt medal was awarded. Amongst these were Rhododendron Maiden's Blush, a pretty hybrid bearing terminal clusters of tubular blossoms, with a spreading corolla $1\frac{1}{2}$ in. across, of a delicate bluish tint; R. Duke of Edinburgh, another beautiful variety, also of the greenhouse class, with flowers somewhat smaller and of a deeper hue than those of the preceding; Cyripedium selligerum, a fine hybrid, the result of a cross between C. barbatum and C. levigatum; its flowers, which are considerably larger than those of the former, have the distinct markings of the latter. Along with these came Dendrobium Rhodostoma, a beautiful hybrid between D. Huttoni and D. sanguinolentum. The collection also contained the handsome Epidendrum Wallisi in a fine flowering condition; also Dendrobium thrysiflorum, Cattleya Mendeli, Odontoglossum cirrhosum, and others. Dioscorea retusa, a graceful greenhouse climber from South Africa, has small flowers borne profusely in catkin-like clusters from the axils of each leaf. Hemanthus cinnabarinus is a fine bulbous plant with immense clusters of orange-scarlet blossoms. Coleus Lord Palmerston is a very distinct kind with purplish-red leaves, edged with green. The same exhibitors also showed the lovely Crinum Macowanii, a variety in the way of C. amabile, but much finer, the flowers being of a deeper shade. Mr. B. S. Williams exhibited a choice selection for the most part consisting of beautiful hybrid Dracenas; also the highly ornamental D. Goldianna and D. lertiginosa, the latter a very

elegant plant with narrow bronze-tinted leaves, very graceful in habit. Adiantum Williamsi is a pretty new Maiden-hair Fern with the pinnae scarcely at all incised, and of a pea-green tint. The very handsome Brazilian shrub, Glomera jasminiflora, was staged in such a condition as fully justified the high encomiums that have been passed upon it, as the specimen shown was nearly 3 ft. across and literally covered with clusters of snowy-white Bouvardia-like blossoms, which admirably contrasted with the rich green foliage. This group was also awarded a silver-gilt Banksian medal. Mr. Wills had a tastefully-arranged group of plants, consisting chiefly of Azaleas, Palms, Caladiums, and Gloxinias, many of the latter being remarkably fine; for these a silver Banksian medal was awarded. A similar medal was awarded to Messrs. Lee, of Hammersmith, for a well-arranged collection. Messrs. Osborn & Sons contributed an effective group, amongst which we noticed the charming little Chilean plant Sarmienta repens, which makes such a capital basket plant for a cool, moist greenhouse. Mr. J. Aldous sent some fine-foliated and flowering plants, which received a vote of thanks. Roses, in the shape of cut blooms, came from Mr. Wm. Paul, Waltham Cross, to which a silver Banksian medal was awarded. A fine collection also came from Messrs. Paul & Son, of the Cheshunt Nurseries, the Tea varieties in which were particularly good. Of Pelargoniums a well-grown group was exhibited by Messrs. Hayes, Edmonton, consisting of Prince of Wales, Fair Maid of Kent, and Duchesse de Moreau. The same exhibitors also staged numerous well-grown examples of a choice strain of Cinerarias, which received a silver Banksian medal; an excellent lot of Erica ventricosa also came from the same exhibitors.

Hardy Flowers.—A highly interesting exhibition of terrestrial Orchids was contributed by Mr. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingley. It consisted of several unnamed kinds of Ophrys, the rare O. Speculum, with a flat lip resembling a metallic-like mirror, edged with rich brown velvet; the yellow-flowered O. lutea and the curious O. aranifera; Orchis tephrosanthos, with bluish-tinted blossoms with deep ananarth lip, was also very fine; Dipodium punctatum, a curious Australian species, with violet-purple flowers mottled with a darker shade, was also shown. A fine basketful of the beautiful Gentiana acaulis came from Messrs. Osborn & Sons, to which was awarded a medal. As usual, Messrs. Barr & Sugden made an excellent display with Daffodils, which, besides the older kinds, contained several new and good varieties. This group was enlivened by cut blooms of Anemone fulgens var. multipetala, the blossoms of which are of a deep scarlet colour. A silver Banksian medal was awarded to Mr. Dean for a superb group of varieties of Primula amena, many of the newer kinds in which were strikingly beautiful; laciniata, with elegantly cut petals, deep rose and pure white coloured, the lavender-tinted Mauve Beauty, purplea, and lilacina were especially noteworthy. A similar medal was awarded to Lily of the Valley Victoria, exhibited by Messrs. Hawkins & Bennett, Twickenham. This is a decided improvement on the original, being more robust in habit, free flowering, and having the flowers a shade larger. Messrs. Veitch & Sons staged a very effective display of Azalea mollis, with flowers varying from almost white to deep yellow and orange-scarlet. These were interspersed by Japanese Maples, with their finely-cut and metallic-hued foliage, and also by numerous well-bloomed examples of hybrid Clematises, amongst which a doubled-flowered kind, Countess of Lovelace, with deep purple blossoms, was very fine. The best of the light-coloured single-flowered kinds were Fair Rosamond, Miss Bateman, Lady Londesborough, and a very deep purple-flowered variety called Duke of Edinburgh. This group was justly awarded a silver floral medal. A group of Rhododendrons was shown in fine condition by Messrs. Lane & Son, Berkhamstead, and received a silver floral medal. Mr. H. Boller exhibited an interesting set of Cacti, consisting chiefly of Mamillarias, of which M. filifera and M. formosa were highly commended. The rare Lowiana variety of Vanda aculeosoma was exhibited by Mr. Heims, gardener to F. A. Philbrick, Esq., Avenue Road, Regent's Park. It differs from the type and the variety Buxalli in having pure white flowers with a violet-purple lip. Cultural commendations were awarded to Mr. Reeves, gardener to C. Hart, Esq., Lee, for Odontoglossum vexillarium, with seven flower-stems; also for a large-spathed form of Anthurium Scherzerianum, and a very finely-flowered variety of Masdevallia Veitchii. Mr. Green showed cut blooms of the curious Gongora portortosa and Alpina nutans; also Crinum ornatum. Mr. C. Turner contributed cut blooms of Tree Carnation A. Alegatiere, a kind with deep scarlet Camellia-like blossoms, 3 in. across.

Fruit.—This was but scantily represented; it comprised Melon Davenport Early, from Mr. Jacques, Davenport Bank, a novelty to which a first-class certificate was awarded. Figs (Brown Turkey and Grösse Monstreuse de Lipari), which received cultural commendation, were exhibited by Mr. Pratt, Hawkstone Gardens, Shrewsbury. Apple Duck's-bill came from Messrs. Coleman, Brede, Sussex.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

HYBRIDS OF SIEBOLD'S PRIMROSE.

THESE most beautiful, easily cultivated, and free blooming hybrids of the fine Japanese species, commonly but, I think, erroneously known as *Primula cortusoides amena*, figured in the "Botanical Magazine," vol. xci., t. 5528, and which I venture to think, with others better entitled to form an opinion than myself, should rather bear the name of P. Sieboldi, have been raised and sent out by two well known firms of florists, viz., M. Victor Lemoine, of Nancy, and Messrs. Dean, of Ealing. Each firm has distributed previous to this year some half-dozen varieties, all of which bloomed well in my greenhouse during the month of April and the latter half of the preceding month. The names of M. Lemoine's varieties are, 1, *Clarkiaeflora*; 2, *vinceflora*; 3, *lilacina marginata*; 4, *fimbriata oculata*; 5, *violacea*; 6, *alba lilacina fimbriata*. Those sent out by Messrs. Dean are, 1, *cerulea-alba*; 2, *cortusoides laciniata*; 3, *lilacina perfecta*; 4, *Mauve Beauty*; 5, *maxima*; 6, *purpurea*. As to the parentage in the way of crossings or fertilisation of the French hybrids, I have little or no information, except that the pollen almost invariably used to fertilise with was that of the species *cortusoides*, which is a native of Siberia, and is figured in the "Botanical Magazine," vol. xii., t. 399; and that the seed bearer was probably P. *lilacina*. As to the English hybrids (which I am happy to say seem to me decidedly the finer set of the two, especially as to size and substance of the individual blossoms), Messrs. Dean inform me that the varieties which they have used as parents have been mostly *lilacina* and *grandiflora*, with the blood of *amena* or Sieboldi, and that a little seed has also been obtained from P. Sieboldi *alba*, but that they are almost invariably shy seeders, and that the quantity of seed obtained at any time is exceedingly small. The following descriptive notes of some of the best and most distinct of these beautiful hybrids (which every lover of his greenhouse should, as soon as possible, add to his collection if he does not already possess them) may not be uninteresting to your readers:—

1. *P. Clarkiaeflora* (L.).—Bloom medium sized, deeply fimbriated, of a fine magenta colour. A very free and profuse bloomer, one of my plants bearing as many as eight spikes. It also produces more pips on the truss than any other variety, some of my trusses having as many as thirteen pips; and it is very quick to increase.

2. *P. lilacina marginata* (L.).—A rather shorter-stemmed variety than the others, with pips rather above the medium size, of which from five to eight are usually found on each truss. The centre of the inside of the flower is pure white, while the margins are more or less deeply flecked with the clear lavender colour of the reverse of the flower. This is a very pretty variety, and, apparently, rather easier to get to seed than any of the others seem to be.

3. *P. fimbriata oculata* (L.).—A profuse blooming, shorter-stemmed variety with pips of much smaller size, opening quite flat and minutely fimbriated. Colour, deep lavender with a clear white eye.

4. *P. vinceflora* (L.).—A very free-blooming variety with shorter flower-stems than most of the others, and having medium-sized pips of fine substance and of a deeper shade of violet than any other, with a distinct white eye. Flowers open, quite flat. An extremely pretty variety.

5. *P. cerulea-alba* (D.).—A very fine variety with pips quite as large as a crown piece; they open quite flat, the inside colour being pure white, while the reverse is of a fine bluish-lavender. From six to seven pips are produced on each truss of this variety.

6. *P. lilacina perfecta* (D.).—The tallest-stemmed of all the varieties, and one which has very large-sized pips, which, however, never open quite flat, but always remain more or less cupped. The ground colour of the inside of the flower is pure white, but almost the whole of it is washed with deep lavender, the colour of the reverse of the flower. There are from eight to nine pips on each truss. An exceedingly fine variety.

7. *P. Mauve Beauty* (D.).—A rather shorter-stemmed variety with good trusses, consisting of from eight to ten pips borne closer together on shorter foot-stalks. The flowers open quite flat, and are of fine substance, the inside colour being the purest white, the reverse pale lavender. A charming variety.

8. *P. Lavender Queen* (D.).—A very fine variety somewhat closely resembling *P. cerulea-alba* above described; the individual pips, however, are rather smaller, and are borne on shorter foot-stalks; consequently they are closer together in the truss.

9. *P. maxima* (D.).—A fine variety with deeply cupped pips, eight of which are usually to be found on each truss. The interior colour is white, the exterior deep rose colour.

10. *P. laciniata* (D.).—A beautiful variety of the same fine deep magenta colour as Lemoine's *Clarkiaeflora*, but with much larger and more deeply-laciniated flowers than those of that variety, not, however, so freely produced, only from six to nine being found on each truss, and the flower-stem being also considerably shorter.

M. Lemoine has also sent out this spring five more named varieties of these beautiful plants, named respectively *Beauté*, *Gaieté*, *Joyau*, *Venus*, and *Virginal*. Having only just received these, though some of them were in flower when they reached me, it would, of course, not be fair or fitting to express any opinion as to their merits till next season, when they shall have become established in their new home, and when it is to be hoped they may prove themselves worthy companions of their beauteous brethren above described. There are also two other varieties described by a correspondent in last issue of THE GARDEN, named *Ophelia* and *Allen's Snowflake*, the first-named a deep purple self, and the latter a fine pure white, which, especially the latter, are likely to be desirable acquisitions.

Belgrove, Queenstown.

W. E. GUMBLETON.

WILD FLOWERS FOR THE GARDEN.

IN the present day, when so much of the time and attention of both professional and amateur cultivators is devoted to bedding plants in one form or another, it is hardly to be wondered at that our native British plants do not come in for a fair share of patronage. Mr. A. R. Wallace, who has perhaps travelled through more countries than most living naturalists, has repeatedly called attention to the fact that the floras of temperate climes present more vivid displays of colour and beauty than are to be found in those of tropical lands, and he points out that the erroneous ideas usually held as to the flowers of the Tropics are due to the fact that we are accustomed to see collected together in one house the most brilliant and showy plants from all parts of the world. If exception be made of the wild *Hyacinth*, *Primrose*, and one or two others, it is but seldom that any of our native wild flowers are to be found in any but the garden of the botanist. There are, however, many species that are deserving of cultivation, not only from a botanical point of view, but on account of their intrinsic beauty, and they may often be advantageously used in conjunction with exotics. The *Creeping Jenny* (*Lysimachia Nummularia*), one of the best known, is well worth growing. It is by no means an uncommon plant, and may frequently be met with in damp places and by stream sides. For a small rustic basket nothing can be better than this plant, together with a few *Lobelias*, and perhaps a *Fuchsia* or white *Platargonium* in the centre, the bright blue of the *Lobelia* forming a fine contrast to the golden-yellow blossoms of the *Creeping Jenny*, which are produced abundantly on the long stems overhanging the sides of the basket. Of other creepers, the Ivy-leaved *Toadflax* (*Linaria Cymbalaria*) and Ivy-leaved *Campanula* (*C. hederacea*) are both worth growing, though neither of them is so showy as the above. In an open, tolerably dry border, the following are a few species that may be cultivated with advantage, viz., *Geranium sanguineum* (crimson), *G. phæum* (deep purple), *G. pratense* (purple), *Potentilla rupestris* (white), perhaps the most beautiful of our native *Cinquefoils*, and *Potentilla verma*, which forms in May a mat of green, dotted all over with golden-yellow flowers; the common *Rock Rose* (*Helianthemum vulgare*), *Malva moschata* (the Musk Mallow), the *Wood Vetch* (*Vicia sylvatica*), as well as *V. Orobus*, two very graceful plants, but neither of them seems to take very kindly to cultivation. Most of the above thrive in pots in a cold frame. If there be a piece of ornamental water, or a fountain basin, the following will be found valuable acquisitions: The *Marsh Marigold* (*Caltha palustris*), the *Globe-flower* (*Trollius europeus*), the flowering *Rush* (*Batium umbellatus*), the *Galinsage* (*Cyperus longus*), a member of the Sedge tribe, and one of our most graceful and elegant plants; the *Water Lobelia* (*L. Dortmanni*), and *Villarsia nymphaeoides*, which somewhat resembles a yellow *Water Lily* in miniature. The two latter should be planted 1 ft. under water; the others may be planted on the wet margins of the pond, or in pots about three parts submerged. Some of the plants just named are but rarely to be found wild, but all, or nearly all, may be obtained of dealers in hardy herbaceous plants. Our native *Orchids*, many of which are worthy of attention, must form the subject of a separate paper.

B.

FLOWER GARDEN ARRANGEMENTS.

THERE are many situations where mixed beds, *i.e.*, beds planted with several kinds of plants, may be appropriately placed. The following are a few examples that I have either tried myself or seen elsewhere:—

1. A circle 14 ft. in diameter, consisting of variegated *Pelargonium* Flower of Spring and *Viola Blue Perfection* planted alternately; one standard plant of *Grevillea robusta*, with about 3 ft. stem in the centre; five smaller plants of *Acacia lophantha* 3 ft. from edge, following the line round at regular distances, so that they extend in a circle round the central plant, and about 4 ft. from it, with a band 1 ft. wide of *Alternanthera amabilis* round the outside. This arrangement is always pleasing and attractive. The feathery character of the fine-foliated plants used corresponds well with the lively blue and white groundwork. To be effective *Alternantheras* must be planted thickly, and the soil must be made rich.

2. Oval, 12 ft. by 8 ft., consisting of a groundwork of *Crystal Palace Gem Pelargonium*, with *Lobelia fulgens*, 18 in. apart; good strong plants of the latter only should be used, and they should bear some relation to each other as regards strength, planting the strongest in the centre of the bed. The *Lobelias* like a rich soil and plenty of water, and, under such conditions, are very effective. They must be neatly and securely staked and tied, or the wind may blow them over. All flowers must be picked off the *Pelargoniums*. Two rows of *Lobelia Blue Beauty* or some other good kind round the outside of the bed will finish it off satisfactorily.

3. A bed consisting of a dark-flowered *Heliotrope* with rather small plants of *Abutilon Thompsoni*, mixed in proportion of two of the former to one of the latter. The *Heliotrope* must be pegged down till the bed is well covered and the plants are coming into flower. The *Abutilons* will grow erect, and the yellow-mottled leaves peeping out of the purple *Heliotrope* make a very effective bed, which will be enhanced by having a double row of *Iresine Lindeni* as an edging outside. The mixture is suitable for any shaped bed, but circles or ovals are the most easily planted, and the most artistic in outline.

4. *Mangles' Pelargonium* and *Verbena venosa*. This is a very old form of mixture, and also an effective one, which, in the case of an oblong bed of considerable size, has a fine appearance. A double row of *Pelargonium Harry Hieover* round the outside, and here and there a plant of the dark-leaved *Castor-oil plant* (*Ricinus Gibsoni*) planted about the bed, adds to its effect. The bottom leaves of the *Castor-oil* plants should be taken off to lift the tops well up, and admit light to the plants below.

5. A circle 12 ft. in diameter, consisting of variegated *Pelargoniums* and *Coleus Verschaffelti* planted alternately, and supported by a broad band of *Gibraltar Pennyroyal* outside, with small circles of *Alternanthera* dotted along it at regular distances apart, and one plant of *Dracæna indivisa* in the centre.

6. Circle 10 ft. in diameter planted with tuberous *Begonias* thinly on a groundwork of variegated *Mesembryanthemums*.

7. White *Fuchsia Rose of Castile* on a groundwork of *Iresine hirsuta*.

8. Balsams planted thinly on *Sedum glaucum*.

9. Mrs. Pollock *Pelargonium* and the old mauve-coloured *Viola cornuta* planted alternately.

This list might be extended indefinitely, and might include mixed beds of fine-foliated plants of large growth only, as well as succulents, such as *Aloes*, *Cacti*, and *Echeverias*. Most people have seen at some time or other what a very pleasing group has been made with the odds and ends of plants left after the parterre has been planted; and a group of this kind will fit in wherever a central bed is desired. Pink and white *Pelargoniums*, planted alternately in a large mass, have a very good effect, being soft and pleasing in colour.

E. HOBDAV.

PENTSTEMONS AT HOME.

THE following are natives of California, where, in their wild state, they fill the valleys and cover the hillsides with the gayest of blooms from May to October. Within California and its vicinity there have been found some twenty odd varieties, all fine plants, but I shall only speak of a few of the finest, and which I deem most worthy of cultivation.

PENTSTEMON SPECTABILIS.—This, one of the handsomest species, grows from 2 ft. to 4 ft. high. It is found on dry hillsides, blooms continually from May to October—the drier and more sterile the place the finer the bloom; I have seen it in flower where the ground was as hard and dry as a brick. The flowers are borne in long panicles, often 2 ft. long, loosely many flowered; corolla nearly

1½ in. long, the short tube suddenly expanding into a wide ventricose throat. In colour, the throat and tube are a rich purple, while the lobes are a clear blue.

P. RICHARDSONI grows from 2 ft. to 3 ft. high, and makes a branching, well-shaped plant. Flowers in loose, irregular panicles; corolla with an ample inflated throat, the upper and lower lips widely spreading. Colour, a clear violet throughout.

P. CENTRANTHIFOLIUS.—This, our most showy species, grows from 2 ft. to 3 ft. high, and has panicles from 1 ft. to 2 ft. long. Flower with a narrow tubular corolla over 1 in. long. Colour, a bright scarlet-red. Very dry grounds.

P. MENZIESII.—A fine variety, and one which makes well-branched plants 1 ft. high. Flowers with a gradually expanding tubular corolla ¾ in. long. Colour, from light to deep pink. Flowers in short panicles. Grows in high, dry situations, where it blossoms finely.

P. ANTIRRHINOIDES.—A handsome variety, growing from 1 ft. to 3 ft. high. Corolla with a very short tube and wide, open mouth, the upper lip of which is arched, and lower recurved. Flowers borne on single peduncles, terminating leafy panicles. Colour, pure yellow, for which it is remarkable. There is a very near species of the above known as *P. breviflorus*, reported as having a flesh-coloured corolla streaked with pink. Height, shape of corolla, &c., not known.

P. CORDIFOLIUS.—A peculiar variety with long sarmentose branches from 3 ft. to 4 ft. long; scrambles over bushes. Flowers in leafy panicles; corolla with a long, narrow tube 1½ in. long, the upper lip erect, and quite ½ in. long. Colour, bright scarlet.

P. GLABER.—This is the most common species reported from Oregon and eastward of the Rocky Mountains; grows from 1 ft. to 3 ft. high. Flowers in narrow panicles 1 ft. long; corolla from ¾ in. to 1 in. long; tube narrow, opening into an oblong, funnel-form throat. Colour, blue to violet-purple.

P. ROEHLII.—Grows from 6 in. to 1 ft. high, flowers in compound panicles. Corolla ½ in. long, funnel form above the narrow tube. Colour light violet-blue.—"Gardeners' Monthly."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Pansies and Violas.—I grow great numbers of the bedding varieties of these, and it may, perhaps, be of general interest if I mention some of the characteristic qualities of the various kinds as exhibited here. This year the earliest has been *Golden Queen*, a yellow, much resembling *Dickson's Golden Gem*, but earlier and larger and quite as free. I have *Sovereign*, *Golden Gem*, *Corisande*, *Golden Prince*, and *Cloth of Gold*, but for a spring-bedding yellow I give the place to *Golden Queen*. Next in order come (1) *Pansy Blue King*; (2) *Viola Acme* and *Admiration*; (3) *Tory*, *Blue Bell*, and *multiflora*; (4) *Holyrood*, and a host of *Violas* and *Pansies*. The most beautiful *Viola* grown is, in my opinion, *Holyrood*, but I am not sure that it blooms freely enough to be a perfect bedder. As an early spring bedder *Admiration* well merits its name. A very beautiful bed here just now is the following, *viz.*, a circle 12 ft. in diameter planted thus: (1) an inner circle of *Golden Queen Viola*; (2) two rows of *Tory*; (3) two rows of the pink-flowered *Daisy Ancebe-folia*; (4) two rows of *Blue Bell*; (5) edging of *Pyrethrum Golden Feather*. For a beautiful summer bed it would be difficult to surpass a mixture of pink *Pelargonium* (says Mr. Halliburton) and *Viola multiflora*; it is barely possible to have a more delicate and charming combination. Its absence of glare and perfect repose is a treat to eyes sore with the garish splendour of modern flower beds. A noteworthy characteristic of this abnormal season is that *Pansies* and *Violas* are earlier than *Daisies*. With us the former are, for the most part, in full bloom; while the latter have scarcely a flower upon them, and seem to be devoting their energies to leaf-growth. Is this experience general?—HERBERT MILLINGTON, *King Edward's School, Bromsgrove*.

A Few Facts about Alpine Plants.—Last year I gathered seeds of *Gnaphalium Leontopodium* (the Edelweiss), and this spring they were sown in pans, well drained, and filled with peat, and kept in a cold frame. They germinated freely, therefore I had hundreds of seedlings, which I pricked out into small pans filled with peat mixed rather finely with broken pieces of sandstone. Amongst other Alpine plants recently received from the Tyrol, *Saxifraga cæsia* (the Silver Moss) is a singular object when in flower; the blossoms are white, and are borne in small panicles on thread-like stems about 3 in. high. Amongst *Primulas* the charming *P. farinosa*, with its silvery leaves and lilac-purple flowers, is at present finely in blossom. Allied to this species is *P. longiflora*, the flowers of which resemble those of *P. farinosa*, except that they are on longer stalks, and are

also generally of a deeper colour; it is a native of the mountains of Austria and Italy. *Ranunculus alpestris*, a pretty though diminutive species, with dark glossy green leaves and white flowers, is now in bloom and very interesting. *Helianthemum alpestre*, a dwarf-growing species with beautiful yellow flowers, has a fine appearance; it comes from the Tyrol. This year flower garden work will be far behind the usual time, as we shall have, to all appearance, to wait till the beginning of June before any warm, settled weather sets in.

—LOUIS KROPATSCH, *Laxenburg*.

Bedding Violas.—We are pleased to see from the remarks of your correspondents, that bedding Violas are flowering so freely in the south this season. In October last we planted out a large number, which stood the winter well, and for some time they have been blooming profusely; without them, indeed, our borders would have been dull this spring, when all flowers are so much later than usual, and even Wallflowers and Stocks have been destroyed by frost. We send you blooms of the following varieties, in order that it may be seen what fine colours exist amongst these Violas for early spring bedding, viz., *V. Acme*, Canary, Brilliant, Grieve, formosa, rubra lilacina, stricta azurea, stricta cygnet, picturata, The Tory, multiflora, Snowdrop, Holyrood, Sovereign, Pilgrimage, and Dickson's White Bedder.—DICKSON & Co., *Waterloo Place, Edinburgh*. [All handsome, but Holyrood especially so; indeed, matchless as regards colour.]

BOG PLANTS.

IN the remarks on these (p. 201) it is stated that the common British Sundew (*Drosera rotundifolia*) thrives in company with the American species, which the writer states should be grown in coarse river sand. I am not familiar with the North American kinds, but I have often gathered *D. rotundifolia* in morasses in Scotland, and

Common Butterwort (*Pinguicula vulgaris*).

may mention that I never found it growing anywhere but on the surface of Sphagnum Moss, where it spreads and thrives wonderfully. In such situations the ground was always soaked with wet, but there was no standing water within 1 ft. or 2 ft. of the surface of the Sphagnum, and the Sundew roots were confined to the surface of the Moss. I used to grow the Sundew in a tub with a few other native aquatics, and I found that the surest way of getting it to establish itself was to carry away a patch of the Sphagnum with the Sundew in it, and set the whole in the tub half or three parts filled with Sphagnum and water, so that the top layer of living Sphagnum and the Sundew received their supply of moisture by capillary attraction only, which was quite sufficient. The Sundew does not thrive well in the neighbourhood of smoky chimnies. The *Parnassia palustris* I found growing and flowering vigorously in a heavy red soil, close to the side of a loch, and so wet and soft that one's feet sank over the ankles. At the same place the *Pinguicula*, of which the annexed is an illustration, grew abundantly in firm but moist, clayey ground.

J. S. W.

Crown Imperials.—Several notices of these showy-looking bulbs have appeared in the columns of THE GARDEN lately, and much has been said in their praise, with all of which I can readily agree, for I have a clump of them which has remained untouched for some years, and which throws up a number of fine-flowering stems. The white *Anemone japonica* Honorine Joubert has got entangled with them, and when they die down it takes their place; but I wish to draw attention to their value in another point of view, viz., as cut flowers. I do not mean the whole head of bloom, but the separate bells. If one or two of these are taken off and placed amongst other flowers in the base of a March stand, I venture to say that few will look at either without admiring them, and asking what that curious-looking flower is.—DELTA.

Double Primroses. (pp. 323 and 343).—A few years ago a lady living at Strabane, in the north of Ireland, sent me some plants of

the double yellow, two shades of double crimson and deep purple, and we also had then both the double white and lilac. A succession of dry, hot summers entirely destroyed the roots of these lovely spring flowers, leaving with us only the single yellow. Some three years ago we found in a wood at a village not far from Sandon, in Staffordshire, amongst the wild Primroses growing thickly and luxuriantly there, roots with double flowers, the stamens and pistil being changed into petals. Two of the flowers were gathered, and since that time some of the people living in the village have transplanted the roots into their gardens, where, I believe, they still exist and are much prized.—E. EDWARDS, *Maryfield House, Newcastle, Staffordshire*.

VEGETABLE CULTURE FOR MARKET.

ASPARAGUS.—Our chief supply of early Asparagus comes from French gardens, in which it is cultivated on a better system than that followed about London. French Asparagus, which is supplied as early as November, has, therefore, so materially altered the price and demand for English-grown Asparagus, that the Fulham growers and others are continually reducing their plantations, and some have entirely done away with Asparagus to make room for quicker-growing and more remunerative crops. The French Asparagus, which is blanched, and about 15 in. or 18 in. in length, is much stouter-stalked than that grown in England; consequently it commands a higher price than the latter, the usual price at Christmas varying from 15s. to 35s., or even 40s. a bundle of 100 heads, according to the demand and quality of the produce; whilst English-forced produce, which seldom appears much earlier than February in any great quantities, sells for 7s. 6d. to 10s. 6d. per bundle retail, but the grower does not get near that price, and it is, indeed, barely remunerative. Out-door Asparagus in warm early seasons is, however, a paying crop where the soil is suitable to its growth, but in late cold springs the beds do not begin to bear until May, thus materially shortening the cutting season, and likewise the profits; for cutting must be discontinued by the middle or end of June, in order to allow time for a full growth of the shoots before the end of the autumn. This crop occupies the ground for two entire years without yielding any pecuniary return, and, in addition to the ground it thus occupies, great expense is incurred in the way of manure and labour. Although Asparagus begins to produce a little in the third year, it is not until the fourth season that it begins to fully pay for the trouble and expense of growing it. During these three years the same ground would have yielded six, nine, or twelve other crops, each of which would have probably well paid the cultivator. Asparagus, too, even in a young state, is a gross feeder, and whether in the long run it really pays well or not is rather a difficult problem to solve even by the grower.

Asparagus in London market gardens is raised from seeds saved in autumn and sown in rows, from 18 in. to 2 ft. apart, in February among lines of young fruit trees, or bushes, or Moss Roses. The less shaded the ground is the better, but open ground is seldom devoted to this crop the first year. I have, however, seen a field at Isleworth cropped with it, Potatoes, Cabbages, and Brussels Sprouts being planted between the rows. Great attention is paid to Asparagus the first season in the way of hoeing and cleaning and thinning a little if too thick. The succeeding spring, provided the plants have grown strongly, they are transplanted. Market gardeners now seldom plant beds of Asparagus, and such as may exist are giving place to the single-row system. Mr. Steel, of Fulham, had some Asparagus beds containing three rows, planted 2 ft. apart from one another, and from the centre of one bed to that of the next was 9 ft. He had also a few other beds with two rows in each, the same distance apart as in the case just named, but in this instance the beds were only 7 ft. from centre to centre. Mr. Dancer, of Fulham, and some

growers at Barnes and Mortlake still have *Asparagus* on the bed principle. These beds, in addition to the *Asparagus*, yield three rows of French Beans in early summer, two rows of Coleworts in autumn, and three rows of the same in the alleys between them. The method now generally adopted, however, is to plant *Asparagus* in single rows or lines, 6 ft. or more asunder. The ground for the crops having been trenched and heavily manured in the previous autumn, it is marked off into beds with alleys intervening 1 ft. wide. In these beds Radishes are sown in December or January, and in March or April, after the litter for the protection of the Radishes has been removed, the alleys are dug over, and in these the *Asparagus* plants are planted, about 18 in. apart. The Radish crop will soon be removed from the beds, which are then cleaned, slightly forked over, and sown with Beet or Onions, or Leeks are transplanted on them. These crops occupy the space till autumn, when they are cleared off and Coleworts or Wall-flowers planted in their place. Nothing more remains to be done, except hoeing the ground and keeping the plants clear of weeds, until autumn, when after the stalks turn yellow they are cut off. As soon as the ground between the rows after this becomes vacant, the whole receives a heavy coat of rich light manure, and soil to a thickness of 5 in. or 6 in. is drawn over the *Asparagus* roots in the form of ridges. The spaces between are then dug over and again cropped with Radishes, Lettuce, or similar crops. The next year, which is the third from the time of sowing and one from the time of planting, a partial crop is obtained. Only a part of the heads that show themselves are cut, and these only where they are the thickest. This is continued for about three or four weeks, when all the shoots are allowed to grow. After the tops have been cut off in the following autumn, more soil and manure are drawn to the ridges, which by that time have the appearance of Celery rows, minus the plants, with a wide alley between them. The next season a good crop is expected. All shoots, small or great, are cut as fast as they appear, until the end of June, when all are allowed to grow at will, excepting small sprayey shoots that are better removed than left. In the alleys are now planted two or three rows of Coleworts, and in many cases, too, the ends and sides of the ridges are similarly planted; but if Beet had been sown there, it will remain until the autumn. When cutting-down time comes, all the unberried "Grass" is cut and laid in heaps together, whilst the berried stalks are kept separate. The former is carted to the fireheap, or is put under hotbeds when they are made, and the latter are kept for seed in a dry and airy shed. After being stored there for a while, until the seeds become ripe and firm, the berries are separated, washed and dried, bruised, and rubbed in sand, afterwards washed again to clean the seeds, which are spread out to dry, and then stored until sowing time. Before the time for thus clearing the ridges most, if not all, the Coleworts will have been marketed; therefore the surface-soil of the ridges is drawn into the alleys, and into these it is dug rather deeply. Immediately some of Cock's hardy green Coleworts are planted, which are marketable by the end of February, after which the routine of ridge-making is proceeded with. Plantations last in good bearing condition for six or seven years, after which time blanks occur, when it is considered more profitable to break them up than to keep them longer. When such is the case they are cut from during the last year of their existence as long as the result will pay for the trouble, and if it is thought that the roots will afterwards be of any use for forcing, they are permitted to occupy the land till November, when they are lifted for that purpose, but if too poor for that purpose they are uprooted at once; the ground is levelled, manured and dug, and planted with Broccoli and Cabbage. The ordinary long saw knife is the

instrument used in cutting, and the men and women employed in market gardens are adepts as regards its use. They slip down the blade alongside of the shoot, and with a peculiar twitch, sever the stalk from the crown without injuring it or the advancing shoots in the least. The heads when cut are laid in heaps on the ridges, afterwards to be packed in long Grass from the field, collected into baskets, and conveyed in a cart or barrow to the sheds, where they are washed, tied into bundles of 100 (105), and are that night, or early the next morning, sent in large square hampers to market.

Previous to this, however, I should have stated that the heads are sorted into three sizes, the best being sold at the best prices, the second cheaper, and the third, for soup or flavoured, at a nominal rate. The yield of *Asparagus* per acre depends much upon the season, soil, and situation, and also the mode of culture. In some of the French *Asparagus*-growing fields from 300 lb.—or, in unfavourable years, still less—up to 1200 lb. per acre are obtained. According to quality, the produce is divided into first, second, and soup *Asparagus*, the first being worth, on an average, 1s. to 1s. 2d.; the second 6d. to 8½d., and the third 3d. to 4d. per lb. In some cases, even in poor seasons, 40,000 lb. of prime quality, the produce of 125 acres, have been sold at 1s. per lb. It thus realised, without taking second rate and soup *Asparagus* into account, over £16 per acre. Although the first outlay in raising *Asparagus* is somewhat considerable, the cost of cultivation, &c., per acre, if the average of several years be taken, does not, it is estimated, exceed £25; and as the gross return amounts to between £35 and £50, in exceptionally favourable years reaching even to £120, the margin for profit is ample. English growers should, however, one would think, by intercropping, realise more profits than French cultivators, who allow their plants much more space, both between and in the rows. Nearly every market gardener has some particular kind of *Asparagus* which he grows and likes best, but the one most grown is a variety cultivated by Mr. Dancer, of Chiswick. Mr. Harwood, of Colchester, a grower for Covent Garden Market, sows spring Onions all over his *Asparagus* ground the first year after planting, care being taken to remove all that come up too near the crowns of the *Asparagus* plant. As soon as the Onions are gathered, a dressing of lime dust, soot, salt, or other manure, is applied to the beds, and covered over with a few inches of soil from the alleys. Manure is always preferred to other dressings, as it enables the shoots to push easily through it the following season. The second year a row of Cucumbers is grown in each alley, which is previously well manured and dug. In March of the third year the beds are faced up, the quantity of soil being put on thick enough to allow of the stalks to be cut 7 in. long. Mr. Harwood, who has taken many prizes for *Asparagus*, cuts such stalks 10 in. long, and the following is the weight of some of the prize bundles, consisting of fifty heads each, in respective years: In 1872, one bundle weighed 7 lb.; in 1873, 7½ lb.; in 1874, 8 lb. 14 oz.; in 1875, 8 lb. 2 oz.; and in 1876, 100 heads weighed 15½ lb.

PEAS.—Of all vegetables brought to Covent Garden Market none, perhaps, are more esteemed than early Peas, and to the grower they are, in good seasons, a remunerative crop. Nearly all market gardeners near London grow them largely; and although French Peas are sent to market early in May, and sold at cheaper rates than English growers could afford to produce them, preference is always given to home-grown Peas, for which there is always a good demand until about September. After that time the ground is occupied by crops likely to pay better than late Peas. Until the end of October, however, fine examples of the Ne Plus Ultra type may be obtained ready shelled in the market, the produce in many instances of

the Surrey fields, Bedfordshire, Essex, and adjoining counties, from whence come the greater bulk of both early and mid-season Peas to Covent Garden. In making early sowings it is a practice with market gardeners to choose a fine day to break down the ridges (the ground being previously manured and cast into ridges), measure off the lines and draw drills in the forenoon, and to leave them open till the afternoon, so that the soil in them may dry a little, and become thereby warmer; then to sow the seeds and cover all up before the evening. The drills vary from 2 ft. to 3½ ft. apart, according to the vigour of the sorts which are to be sown. In the close lines, Lettuces or Spinach are used as inter-crops, but in the more distant ones Cauliflower is the crop usually planted. In many instances the first sowing of Peas is made in December on a warm border; but, considering that they must be sown a little deeper than in January, and the risks to which the seeds are liable from mice, birds, insects, and damp, it is a much-disputed point among good growers whether the December sowing has any advantage over that made in January, many contending that the produce of the latter is quite as early as that of the former, and the crop less subject to risks. Different growers have a preference for different kinds; but the early dwarf kinds are universally the most desired, on account of their quick returns, the small space they occupy, and because they require no stakes. Beck's Little Gem is much liked for an early crop, on account of its dwarf habit and good qualities. Other sorts highly esteemed by market gardeners are Early Frame, Croom's Dwarf, and Bishop's Dwarf. As a rule, they are sown for a first crop in January, and invariably on a dryish soil, and in as sheltered a place as possible, other sowings being made fortnightly in succession till April, or even till the 1st of July. William the First is a fine early Pea for market purposes. It is of about the same height and habit as Sangster's No. 1, and equal to it in earliness; but the pods are larger, fuller, and greener. Maltum in Parvo is also largely grown in many places as a market Pea with the best results, coming in, as it does, quite as early as Sangster's No. 1, but having larger pods, while the Peas are as delicious as Veitch's Perfection. It grows to a height of from 16 in. to 18 in., can be sown in rows 20 in. apart, wants no laying, and if cut by frost, as the early Peas often are, it will send up a profuse second growth that will bear a heavy crop. Laxton's Omega, on account of the deep green colour of its pods and Peas, is also a good market Pea. It is a dwarf Ne Plus Ultra, but harder and as good a cropper; the pods fill well, the Peas being still soft and juicy when the shells are full to bursting; it is a fine dwarf late variety.

Sticking Peas is seldom resorted to in market gardens, the haulm being allowed to lie on the ground. Gathering is a matter well attended to, as the oftener the pods are picked when full the longer do the plants continue to bear. Most market gardeners save their own seed, and, indeed, some grow Peas for seed only; in this case the haulm is frequently shifted from one side of the row to the other, in order to prevent the pods from rotting, from being destroyed by snails, and to expose them to the air and sun, and thus cause them all to ripen alike. When ripe the haulm is pulled up and dried, and taken indoors to be cleared of its seed during wet weather. When the Green Peas arrive in the market, which they do in half-bushel baskets, covered with Rhubarb leaves fixed on the surface by means of Willows, and are disposed of to various salesmen, women shell them in large quantities. All the Peas then, little and big, are sifted, the largest being kept separate, and all spotted or worm-eaten ones are picked from them; they are kept in basins by themselves, and sold at a higher rate than the others, which are in their turn re-sifted and picked, until three kinds and three

prices of Peas are made. I have known some market gardeners in the height of the season pay nearly £100 per week for gathering Peas.

BROAD BEANS.—These are not grown to any great extent in London market gardens, and although good supplies of them are brought to Covent Garden Market, they are the produce of large fields in what are termed the home counties. A few London market growers produce them for the sake of convenience of cropping, &c., but they are not considered remunerative when the cost of the labour incurred in cultivation, seed, picking, packing, and carting is considered. Where they are grown, however, dry and light soils in warm positions are chosen for early sowings, which consist of the Early Mazagan. Sowings of this kind are made in January, and again in February, in rows 2½ ft. apart, running across or obliquely in the borders or quarters. Large sowings of the Longpod are made in the latter half of February and in March, in rows equally distant, as for Mazagans, but with less particularity as regards the way in which they run, the position of the quarter, or the quality of the soil which they occupy. The Broad Windsor, which forms the principal crop, is generally sown in March. The Green Broad Windsor is preferred by consumers; therefore market gardeners generally grow this sort for the main crop. Beans are sometimes sown on ground occupied by Radishes, with the progress of which they interfere but little, as the Radishes are too small to injure the Beans, and they are sure to be removed before the Beans can be in any way injurious to them. Early Stone Turnips are not unfrequently sown between the rows of Beans, and such spaces are also sometimes occupied with Cos Lettuces, Cabbages, Cauliflowers, and Brussels Sprouts in every second row, Lettuce being in the intervening one. The Lettuces, being soon ready for market, are removed, and thus make a good clearance for a free circulation of air, and a passage from which the Beans off two rows can be easily gathered. Market gardeners, as a rule, do not save their own seeds of Beans, as they find it cheaper to buy them. When seeds are to be saved, the haulm must be allowed to occupy the ground a few weeks longer than it otherwise would do, and thus the chance of cropping it with Savoys, late Sprouts, or Cauliflowers, Endive, and a few other similar crops is lost. As soon, therefore, as the Beans have entirely yielded their crop the haulm is pulled up and carted to the manure heap. Some growers, however, grow Beans for seeding purposes, and in this case about one-half or two-thirds of the pods, consisting of the earliest-formed, are picked off for marketing in a green or usable condition, the remainder being left to ripen. If all were left the seeds would not be so large, plump, or heavy as when the pods are thus thinned out. When the Beans have become well matured, the haulm is pulled up and laid on its side to dry for the remainder of the day, if fine; it is then tied into bundles, dried thoroughly, brought home, and either thrashed at once, or kept under cover or in a thatched stack until a more convenient season for thrashing out the seed occurs. The ground cleared is then dug or ploughed or deeply worked without being manured, and a crop of Endive or white Cos Lettuce is planted thereon for use in October, or Savoys, Brussels Sprouts, Cauliflower, Broccoli, autumn Radishes, Leeks. The season when Broad Beans are in the market is comparatively but a short one, and although they usually find a ready sale, the London public do not appreciate them in the same way as they do Peas, French Beans, or Scarlet Runners. C. W. S.

Spring-flowering Bulbs in Regent's Park.—Notwithstanding the unfavourable weather which we have had, that portion of the park known as the Floral Walk is now rendered gay

by means of a numerous and brilliant display of Tulips and other spring bulbs. By a judicious blending of the various colours the gaudy hues of some of the kinds are effectively toned down by the delicate tints of others—treatment the result of which is highly satisfactory.

THE KITCHEN GARDEN.

NEW POTATOES.

DURING the summer months there is nothing in the vegetable way more esteemed than new Potatoes, but although this is the case, the practice of most growers is to plant all their stock at once; by doing which, the skins of the young tubers are set before the end of July, and therefore cannot be got off without peeling. This not only detracts greatly from their appearance, but the Potatoes are never so good in quality, as there is something in the inner skin that appears to preserve the delicate flavour in cooking. It is a well-known fact that even old tubers which are full ripe are always better when steamed or boiled unpeeled, and young ones that can be presented at table without losing any of their starchy matter, and so finished off as to be just cracking, are as near perfection as possible. To eat when young, the Kidney sorts are the most esteemed, the best of which are the Ashleaf kinds, such as Veitch's and Myatt's, and to have these in succession, it is necessary to make two or three plantings in some open, sunny spot, where they can be afforded light, rich soil, and have plenty of space for the air to circulate well between the rows, which will be the means of rendering the foliage thick and firm, and enable it to resist the attacks of disease, so prevalent when the haulm is in any way drawn. To keep the shoots of the seed-tubers back, they should be spread out singly on light shelves in a shed or cellar, where they can be kept cool by allowing a draught to pass through, and if this is done the growth will be very slow and sturdy, and the sets but little shrunken or wasted, even at the end of several weeks hence. I have had them as late as the latter part of July, at which time when planted they are quickly through the ground and ready for earthing up, and if favoured with a soaking rain just before that operation takes place, the young tubers swell rapidly and are soon fit for use. Managed in the way above-mentioned, two crops may be got off the land the same season, and the spaces set at liberty by the middle of October for planting Cabbage, or anything of that kind to stand the winter. It should be borne in mind that Potatoes saved for late planting should not have their shoots rubbed off; that is, if they are of the Ashleaf Kidney kind, as when divested of their first growth they rarely start again, except to form small tubers around them. The general tendency of Potatoes to supertuberate has been taken advantage of to get young ones in winter, but to do this, the round strong-growing sorts are the best, and the larger the sets of these are, the greater and more satisfactory is the yield they produce. This is owing to the larger amount of stored-up matter they contain, which enables them to pass the summer without shrivelling up in the way those of smaller size would be likely to do; to prevent which, they should be stored in the coolest place that can be found, and have all their shoots rubbed out as they show. To start them in the autumn or winter, all that is necessary is to bury them in boxes of moderately dry earth in layers, and stand them in any situation where they can feel a little warmth, when in the course of a month or six weeks they will be studded all over with clusters of young ones. These, although not so good as those obtained under more natural conditions, are a novelty at that time of year, and are much esteemed by some, and old spare tubers that remain over at the end of the season may be utilised by turning them to this account, as it is better than throwing them away. S. D.

CUCUMBER DISEASE.

I HAVE had considerable experience in the culture of Cucumbers and Melons, and although I have read from time to time accounts of the Cucumber disease in *THE GARDEN*, I never had it amongst my plants until now. I find too, that the Cucumber disease described in *THE GARDEN*, Vol. XIII., is quite different from that in my case. The alarming rapidity with which this disease has traversed the whole range of my pits is astonishing. I first discovered it in an end light on the 9th of May, and now (May 14) it is in thirteen lights, planted with Cucumbers and Melons in the usual way. The soil is composed of turfy loam, leaf-mould, and manure. I cannot form any idea as to what has caused this disease to break out, unless it be minute fungi in the manure and leaves, which form the heating material for these pits. What had I best do to prevent its getting into my Cucumber house which is a short distance off? Shall I destroy all these plants of which I send you samples for examination, or is there any way by means of which I may save the best of them?

A Cucumber grower, four miles from here, has lost all his winter crop through this same disease. J. M.
Gloucestershire.

[The samples which accompanied this communication exhibited one of the most virulent cases of Cucumber disease which we have yet seen. We wish a few fruit had accompanied the leaves, as the disease mostly shows itself in a somewhat different character in the fruits. But more than enough of leaves and stems have been forwarded to prove the case to be one of the worst possible of the Cucumber disease. There are many types and grades of it; some comparatively mild, others running rapidly into wretched masses of rottenness. There is nothing unusual in its spreading so fast; it generally does so; and the strong probability, almost amounting to certainty, is that before it has quite wrecked the plants in the pits it will have attacked the house. It is impossible to account for the sudden appearance of this disease. Soil, skill, treatment, site, continue just the same as usual, and yet, alas! the plants are suddenly crippled or destroyed. It is, moreover, highly infectious, and is often carried from place to place. A neighbourly visit from an infected garden may even bring it. It came here on a plant of Tender and True, and almost vanquished us for two years. Salus decidedly checked it, whether by destroying the disease, or stimulating the plants so much as to help them to make a rush through it, continues doubtful; most probably the latter; and hence, partly at least, originated a change of practice, which has enabled us to master, rather than wholly stamp out, the disease. We observed that the young plants grown in a brisk heat had no disease; it was therefore determined to continue a warmer course of treatment all through. A rise of temperature from 65° to 80°, or 85°, at top and bottom, has suppressed, if not extinguished, the disease. It is, we believe, still here, but it does not show itself. We had proofs of this in the autumn. A cold pit was planted with French Cantaloupe Melons; these got diseased, while those subjected to more heat were free from it. Acting on this fact, our Cucumbers and Melons have had, as has been before stated, more heat than usual, and up till now we have seen no disease. Our advice is destroy the worst plants or the whole in the pits. Thoroughly clean, then add new and more heating material, and make a fresh start. The surest way of sweeping the disease out of the house is to advance the temperature to 50°, or even 90°. With abundance of light and proper care in regard to air, &c., this high temperature is by no means unfavourable to Cucumbers or Melons, while it has proved with us the only sure or certain antidote to the disease.—D. T. FISH.]

GARDEN DESTROYERS.

WIREWORMS.

(*ATHOUS HÆMORRHODIALIS* AND *AGRIOTES LINEATUS*.)

THE grubs of these beetles, as well as those of some nearly allied species, are only too well known to gardeners and farmers by the name of wireworms, and it is perhaps hardly overstating the case to say that they are among the most troublesome foes with which either has to contend, as at times they are in great abundance, and live on and destroy the roots of most garden and farm crops. The grubs of the Tipulidæ (Daddy Longlegs), described in *THE GARDEN* for August 10, 1878, are sometimes called wireworms, but that is quite a mistake; the term should only be applied to the grubs of the beetles belonging to the family (the Elateridæ) to which the insects belong, which form the subject of this paper. Wireworms are generally most abundant in newly-made gardens, particularly if the ground has been previously pasture land. When they are present in great numbers they can only be got rid of by much trouble and labour. There have been many means suggested for keeping this insect in check, but few are of much use unless the ground be well cultivated, and care taken to destroy every one which may be found. No portion of a garden should be allowed to remain undisturbed and covered with weeds for any length of time, for such places form regular hot-beds for the propagation of these and many other insects. Most birds, particularly rooks, starlings, blackbirds, thrushes, pheasants, and partridges, are very fond of wireworms, and if the ground be kept properly worked, so that they can get at them, they destroy immense numbers. Mole also are their deadly foes, and certain carnivorous beetles belonging to the family Carabidæ kill quantities of them. Slices of Potatoes or, in default of these, slices of Beet-root, Turnip, Carrot, &c., or pieces of Lettuce or Rape-cake have been found very useful as baits when buried about 1 in. below the surface near any plants which have been, or are likely to be, attacked by these grubs. Each bait should have a small stick stuck into it, so that it can be removed and examined; this should be done every morning, and the wireworms which will be found boring into the bait destroyed.

Some recommend merely laying these baits on the ground, as being more efficacious than burying them, a plan which is certainly simpler, and might be tried as well as the other. Some plant Daisies, the roots of which the wireworms are particularly fond of, to attract them from any plants they wish to preserve. Gas-lime, and a mixture of lime and fresh soot, well incorporated with the soil, are very effectual in keeping them in check. Common salt strewn over the ground and well dug in (about 6 cwt. to the acre), is also much recommended. Rolling the ground is of little or no use, as the wireworm is so tough, and generally so far below the surface, as to be unhurt by any ordinary rolling, and the ground is made harder, and consequently birds have more difficulty in getting at them. Fortunately, the wireworms are not free from parasites; a very small ichneumon fly finds them out and deposits its eggs within their bodies. They are also infested by a minute intestinal worm. Both these parasites no doubt assist in checking their increase. The beetles should always be destroyed whenever they can be found. They are at times attacked by two species of minute ticks, but it is very questionable if their numbers are reduced by these parasites.

A very successful cultivator of Picotees and Carnations tells me that he always had the earth in which he grew his plants carefully looked over twice on the potting bench to be quite sure there were no wireworms amongst it; and even then he placed a piece of Carrot in

beetles are quite harmless, and may generally be found on flowers, particularly umbelliferous ones, stems of Grass, under stones, &c., during the spring and summer. The females are provided with longish ovipositors, which they can protrude or retract at pleasure; with these they deposit their eggs, which are very small, oval, and whitish, during the summer below the surface of the ground, near or on the roots of some plant. The number of species of which the wireworms are destructive is not exactly known. A very large majority live in decaying and decayed wood, but probably ten or twelve, or perhaps more, are injurious to garden and farm crops. The grubs of the following species, however, are very destructive and very common, particularly those of the first two, *Athous hamorrhoidalis*, *Agriotes lineatus*, *A. sputator*, *A. obscurus*. The wireworms are all long, narrow, smooth grubs, of a yellowish colour, and are very tough and horny, resembling very much the common meal worm in general appearance, and they are tolerably active. They are very long lived and grow very slowly, for they do not attain their full size for five years; at the end of that time those of the largest species are about $\frac{3}{4}$ in. or rather more in length. When full grown they descend deeper into the earth, and form small, oval cells in which they undergo their change to the chrysalis state.

Athous hamorrhoidalis is about $\frac{1}{2}$ in. long; the head is black, with shining eyes of the same colour, and is furnished with a pair of dark reddish-brown antennae, consisting of twelve joints. The thorax is bluish-black in colour, and covered with very minute pale hairs, which are scarcely visible to the naked eye; it is long and narrow, with the sides nearly parallel, and terminating in a spine at each angle of the base; the wing cases are rather wider than the thorax, and are long and narrow; they are not quite as long again as the head and thorax together, the sides are nearly parallel, but gradually converge to a point; they are of a dark reddish-brown colour, covered with fine pale hairs; they are striated with several finely punctured longitudinal lines; the legs are short with long feet, and of a chestnut-brown colour.

Agriotes lineatus is about $\frac{3}{4}$ in. long, and is considerably stouter in proportion than the foregoing species; the head is small and blackish; the antennae are reddish-brown, and consist of twelve joints; the thorax is dark brownish-black, shaded at the edges into chestnut; it is nearly as wide as it is long, and very convex; both sides terminate at the base in a spine; the wing cases are long, oval, and convex, with somewhat parallel sides; they are striated longitudinally with several punctured lines, the spaces between the lines being alternately brownish-black and chestnut; the entire insect is covered with minute pale hairs.

The wireworms of different species are very similar in appearance, but they can be distinguished by the last joint of the body, which varies in form; the distinctions are, however, not worth mentioning here. They are all long, narrow grubs, horny and very convex above. Their bodies are composed of twelve smooth, yellowish joints; the three first each bear a pair of short legs; the last is furnished below with a retractile tubercle, which serves the purpose of a seventh leg; this last joint is generally roundish and flat at the top, and usually more or less toothed at the edge, but varying in this respect according to the species. The first joint of the body is much larger than the three following ones. The head is somewhat darker than the rest of the grub; its mouth is furnished with minute feelers and a pair of strong, toothed, reddish-brown jaws; there are a few scattered hairs on the body. The chrysalis is nearly as long as the perfect insect, and of the same form, all the limbs of which are distinctly visible through the semi-transparent skin in which they are wrapped.

each pot, which was examined every morning, and the plants were not considered safe until the Carrot had not been touched by wireworms for a few days. In 1874, a piece of land near Worthing, which had not been cultivated for two or three years, during which time it had been lying waste, was made into a flower garden; during the first year nearly all kinds of herbaceous plants suffered much from the attacks of the wireworm, particularly Carnations, Pansies, Daisies, Polyanthuses, and Sweet Williams. Whenever a plant was found to be drooping, it was lifted, and a careful search made for the worms, when sometimes five or six would be found on one plant. The second year the damage, though considerable, was much less, the same plan being pursued. The third year the number of wireworms was so much diminished, that no particular care was taken to exterminate them, but every one met with was destroyed, as well as any of the beetles. The garden is now nearly free from them.

Wireworms appear to be almost omnivorous, as far as the produce of kitchen gardens is concerned, and the flower garden fares little better. Such plants as Irises, Ranunculuses, Anemones, Lobelias, Dahlias, Stocks, and the plants already mentioned, are amongst those particularly liable to be attacked. Young trees in nursery gardens often suffer much from these insects. The Elateridae are a tolerably large family, containing nearly sixty British species. The beetles are all long, narrow, and oval, with very long thoraxes; they are usually of a dull brown or yellow colour, but some are more gaily coloured; they are mostly very active and fly well; if disturbed they generally fold up their legs and antennae and feign death, and if on a flower fall to the ground. Their legs are so short, that if one chances to fall on its back it could not right itself, were it not for the following peculiarities in its structure: The thorax is furnished beneath with a small spine (fig. 3A), and which fits into a cavity in the breast when the insect lowers its head and thorax. If the beetle falls, or is laid on its back, it raises its head and thorax, which forces the spine into the cavity; then forcibly trying to straighten itself again, the spine flies out with an audible click, and the insect is raised several inches into the air and generally falls on its feet; if it does not, it makes another jump. The

THE INDOOR GARDEN.

CAMELIAS AND THEIR VARIOUS MODES OF CULTURE.

Pot Culture.—Where small plants only are wanted, or specimens to shift from one house or room to another, healthy plants in pots will always be found most useful. Such plants should always be in the hands of the cultivator when from 15 in. to 18 in. high, and about half these measurements in width. Abundance of little plants of this description can always be purchased, and they are better to begin with than larger ones. They will probably be in 3-in. pots, and when it is found that these are becoming pretty well filled with roots they must be shifted into 6-in. ones. What to pot them in, and when to pot, are not very important questions, as I find that our plants succeed well, potted or planted, at any time, and in any kind of soil; and at the same time it is best to be on the safe side, and for that reason it will be well, especially in the case of young growers, to be careful at first as to the selection of their soil until it has been proved that the roots will not refuse material of a

commoner kind. A mixture of loam and peat, in about equal parts, with a liberal addition of silver sand, makes one of the best composts which can be used for Camellias. Before potting them into larger pots the latter must be perfectly clean and dry; good drainage must also be secured, and it is a good plan to place a thin layer of Moss over this before putting in the soil. In beginning to pot, a few of the roughest pieces of the material should be placed at the bottom, and the ball kept entire should be set on this. The soil should then be put carefully round the sides, ramming it down firmly, and leaving the surface of the old ball just covered and no more. After potting, if the plants are about to start into growth, they should be placed in a moist, partially-shaded house in a temperature of 55° or 60°. They should remain no longer there than the roots get hold of the new soil, as, after that, full exposure to the sun and less moisture in the atmosphere suit them best. When Camellias are potted, after the flower-buds are formed, but not opened, they should not be excited into growth in any way, but be allowed to quietly establish themselves in the new soil. For my part I would just as soon pot Camellias when the buds are half swelled as immediately after the blooms have fallen. Plants of tolerably good size may be grown in 6-in. pots, and when too large for these a 10-in. pot will generally be found to be a suitable shift. From this they may be shifted into 14-in. pots, each time using the same compost as that recommended in the first instance. The general culture of Camellias in pots consists in keeping them always potted in good sweet material, keeping the roots constantly moist, as nothing injures the Camellia so much as drought at the root. During the time when the most tender part of their growth is being made they may be kept in a somewhat close, moist, warm atmosphere, but whenever growth seems at an end let them be fully exposed to sun and air. Except when newly potted, they should never be shaded; indeed, if they can be accommodated with an unshaded house during the summer and autumn, so much the better, but after growth is completed—say from the middle of June until the end of September—they do well placed out-of-doors in a situation sheltered from wind, but fully exposed to the sun. The bloom-buds often drop to a greater extent under pot culture than under any other mode of treatment, and in nine cases out of every ten bud-shedding is either the result of bad drainage or of drought some time or other. The foliage must at all times be kept quite clean, either by means of sponging or syringing. Nothing sets off Camellia blooms to greater advantage than fine, healthy, clean foliage.

Box or Tub Culture.—When Camellias become too large for ordinary-sized pots, rather than allow them to become deteriorated from want of proper root-room, let them be planted in large round tubs or square boxes. This mode of growing them may be called pot culture extended, as in planting and general requirements the one requires the same attention as the other, but when once established in a large tub or box they do not require to be often shifted, twelve years being not an unusual period for plants to remain in the same box. Our largest specimens stand out-of-doors from the middle of May until the middle of October. They are wintered in a large cool house, and they bloom superbly during March, April, and May. When established, watering copiously at the root constitutes the chief attention which they require. For convenience of shifting about and general decoration, small-sized pots will, however, be found of greater service than either tubs or boxes.

Planted Out Under Glass.—Of the various ways of growing the Camellia indoors this is by far the best; thus treated, they grow better, bloom more profusely, and the blossoms open in succession for a greater length of time. Several bushes in the conservatory here bloom from before Christmas until after Easter, and we can never insure anything like this in the case of pot or box plants. From one plant alone of the double white we cut, during December, January, February, and March, over 1000 blooms; and yet it is not a very large plant, being only some 10 ft. high and about 4 ft. through. Beds for Camellias may be of any size, from 3 ft. square and 2 ft. deep to those of larger dimensions. Here, as in potting, perfect drainage must be secured before planting is attempted. The soil should be much the same as recommended for pots, only rougher, and a dash of charcoal in it will be an advantage. Both before and after planting the soil should be firmly trodden with the feet. The planting may be done at any time, except when the blooms are open. To plant them would probably cause them to fall prematurely. Last February we planted about a dozen Camellias, all set with buds. After planting, they were liberally watered at the root and syringed overhead; since then they have all produced some very fine blooms, and they are now making vigorous growth. Either young or old plants may be planted out, but when they become too large for pots and boxes, invariably the best plan is to plant them out, spreading out the roots a little if they have previously been twisted round the pot, but a thorough breaking up of the ball should not be attempted, unless the soil about the roots be in a very bad con-

dition. After they begin to grow they must be copiously watered and, with plenty of moisture at the root, syringing overhead is not so much needed, except for the purpose of keeping the leaves clean. If the weather happens to be very sunny when planting, and especially if they have started into growth a little, a slight shade should be afforded them for some ten or twelve days, but after that they should be fully exposed; that ripens the wood, matures the buds, and ensures a profusion of blossoms. Camellias may be planted out against conservatory walls, to which they should be trained. When Camellias become too large for the purposes for which they are wanted, they should be cut in just before growth commences, and any having long bare stems may be cut back with every certainty that they will push shoots further back from the old wood, provided they are treated the same as plants just starting into growth. Early blooms may easily be secured by starting the plants early into growth, and having the buds ripened well early in autumn. Camellia blooms in November, December, January, and February, I need scarcely say, are much more valuable than they would be about this time of the year. When kept clean and healthy, few or no insects harm Camellias.

Open-air Culture.—Camellias are now conclusively proved to be hardy, a fact, however, by no means new; but they are not grown out-of-doors so plentifully as they should be now, yet in so many parts of the country June is the best month in which to plant them out, and where they have been wintered in a close house they should be, as it were, hardened off before they are finally planted out. The best situation for them is one well exposed to the sun, but sheltered from strong winds, which prove more disastrous to the flowers than anything else. No greater mistake could be made in the case of outdoor Camellias than planting them in a shaded "nook." In such a position they might be well protected, but that would prove anything but a benefit to them in the end, as full exposure in summer promotes free flowering, and renders them proof against frost. When the pit is made for their roots two or three barrowloads should be taken out, and the same kind of material as that recommended for indoor plants should be substituted. In planting, this must be well and carefully pressed against the roots, and after that is completed, if they are planted on lawns, the turf should be laid neatly down again around their stems. Immediately the planting is done a good watering should be given, and this should be repeated once or twice a week while the weather remains dry. In excessively hot and dry weather a mulching of rough manure is of much service over the roots for the first few months, and until such time as the roots have taken a firm hold, one or two stakes, sufficient in strength to hold the plant steady, should be put to each. When planted, during the first winter, if they have not become quite established, and the weather should prove severe, it is a good plan to protect them a little with old mats, or in some way or other, but these should be put off or kept on according to the state of the weather.

The following is our selection for both indoor and outdoor culture, viz.: Double white, *Angustina superba*, Beali, *Chandleri elegans*, *Lavinia Maggi*, Countess of Derby, Countess of Eversmore, Countess of Orkney, Cup of Beauty, *fimbriata*, Jenny Lind, Jubilee, Lady Hume's Blush, *Mathotiana alba*, Mrs. Abbey Wilder, Queen of Beauties, Rubens, and Wilderi.

CAMERIAN.

HARDINESS OF CAMELLIAS.

The ability of Camellias to live out-of-doors unprotected in England appears to be something new to several who have written of late respecting them; but their hardiness has been long known in some districts not nearly so favourably situated as the places instanced. I could have pointed to examples of the old Double White and others 200 miles north of London a score of years ago that had then for a similar length of time stood out in a shrubbery border uninjured. There can be no objection to any one who happens to have spare plants or feels disposed to so turn them out doing so; but except in the most favoured spots on the coast the result will be these or any other plant that naturally blooms so early, can never be satisfactory, and even such exceptional places only very partially so. The time when Camellia flowers are most required is from October to April, a season long enough to satisfy most people, although it can be extended much longer than that where desired; and the disposition to thus bloom through the winter months is one of the greatest merits of this most beautiful and useful of flowering shrubs. "A. D." speaks of the thousands of Camellias that are starved and killed in pots and tubs, a statement which is quite correct; but this is not the fault of the plant, or any evidence of its unsuitability for that description of culture; so treated, as well as planted out, and in both cases grown under glass is its legitimate position in this country; its flowers are too susceptible of injury from spring frosts and of being chafed by the wind to admit of more than very partial success out-of-doors.

although the plant itself is quite as hardy as many that are all that could be desired in the open air without any protection whatever. It is desirable to grow all the plants possible out-of-doors that will endure our climate, and that bloom at a time of the year when their beauty can be fully developed and enjoyed; but when their nature is such as not to admit of this, except as curiosities, and for those who have no convenience for treating them in accordance with what they require, Camellias, or anything else of a similar character, merely occupy a place that could be much better filled by other shrubs.

T. BAINES.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Sarracenias at Chelsea.—At Mr. Bull's nursery there is now an extensive and interesting collection of these singular plants; they fill the whole of one side of a span-roofed house some 60 ft. long. Most of them were imported last summer, and since then have made growth more like that which they usually produce in two or more years than the result of a single season. The plants are almost touching the roof glass, and up to the middle of May have never been shaded in the least, nor, we understand, will be, unless the sun is found later on to burn them; this treatment very much intensifies their colour. They comprise *S. Drummondii* rubra and *S. flava* major—the true very large-growing variety with its great veined lid. This is very scarce, and much the largest and finest species yet known. In the same collection were also other forms of *S. flava*, the singular small-growing *S. psittacina*; *S. variolaris*, very strong; *S. purpurea*; the hitherto scarce *S. rubra*, with its violet-scented flowers, that, independent of their quaint singularity of form and rich maroon-coloured petals, are deserving of cultivation for their perfume, as a single bloom will scent a whole house. Amongst these is a very distinct new kind, in form in the way of *S. rubra*, but evidently a large and free flowerer, with stouter pitchers than those of that kind. Some of the first formed since it was received have attained a height of from 20 in. to 24 in., and stout in proportion, but its most distinctive character is exhibited in the lid, the inner side of which, over some three-fourths of its velvety surface is dark chocolate, the colour quite solid and distinctly defined from the lower central portion of the lid, which is netted over with the same colour on an olive-green ground. It is a very distinct and welcome addition to this not over-numerous section of Pitcher plants, which are gradually making their way in the estimation of plant growers, since their cultural requirements have become better understood; and it has been found that they thrive and attain a condition of high colour in their pitchers, which so much enhances their appearance in a much lower temperature than that to which they used to be subjected, and which was alike destructive of both healthy vigour and appearance. With them were associated a beautiful lot of *Droseras*, distinct species, in excellent condition, and a quantity of thriving *Dionæas*; also the New Holland Pitcher plant, *Cephalotus follicularis*.—P. G.

Large *Dionæa muscipula*.—I think that with a little care in selection we might soon have a much larger variety of this highly interesting plant than that which one generally sees in cultivation. I have at the present time two fine seedlings growing at the cool end of our intermediate house here, along with cool *Odontoglossums*, &c., which present very striking differences, both in general habit and in the colour of the leaves. One is the common variety, with green leaves produced in abundance, and it measures about 6 in. across, and the other has petioles about 4 in. in length, of a purplish-red colour, and leaf-lobes quite 1 in. long, exclusive of the bristles or teeth, which measure $\frac{1}{2}$ in. in length. When laid down in the natural way the leaves extend considerably over the rim of a 9-in. pot, and have to be tied up in order to get the bell-glass on the pot. Both plants are growing together under exactly similar conditions in 2-in. pots, plunged in Sphagnum within another pot of size sufficient to hold a bell-glass, and they are kept constantly wet, air being admitted at both top and bottom of the glass. A greenhouse or cold frame is said to be warm enough to grow the *Dionæa* successfully, and this may be so during the summer, but I find that during the greater part of the growing season such quarters are too cool for it, as the leaves lose their vitality to a great extent. I put one plant at the warm end of a greenhouse for a fortnight, and in a short time the leaves refused to close on any object that was placed within them, but when restored to its old and warmer quarters it recovered its sensitiveness in a short time.—J. S. W.

Gloxinias all the Year Round.—Few plants are more useful or more accommodating than *Gloxinias*. They may be grown by anyone who has a pit heated by fermenting material or otherwise, and a greenhouse to put them in when coming into bloom, which should be some time between June and September. For the last

fourteen months we have never been without some plants of them in bloom, the number ranging from six to thirty at a time. We find them most useful, especially when grown in 5-in. pots, the size in which we mostly grow them. I find them useful for mixing with Ferns and fine-foliated plants for house decoration, and also in the shape of cut flowers for filling vases in winter. A few blooms of these, and a few of other light-looking flowers, together with Fern fronds, have a pretty effect in a vase, and are sure to be appreciated in winter. We grow a batch of them for conservatory decoration during summer; these are started the first week in April, and we keep potting a few the first week in every month during the first ten months in the year; this gives a good succession. Our stock of bulbs is upwards of 150. We sow a packet of seeds in March, the seedlings from which bloom in August and September, when the best of them are picked out and saved for stock, but as good bulbs may be bought cheaply, some who have but little room may prefer that course to sowing seeds. To the amateur *Gloxinias* may be strongly recommended, seeing that they are at rest during winter when room is most valuable. They are neither difficult to grow, nor do they want much heat.—J. C., Farnborough.

LAST WINTER'S DISASTERS.

I HOPE that a careful record will be kept of the disasters among tender plants from the cold of last winter. Whatever has stood but slightly injured may be in future considered as safe. I am afraid Ireland, where the soft rains of the Atlantic and the high winter temperature have led to a good deal of experiment in planting out the hardier exotics, has suffered a good deal. I have lost *Fuchsias*, *Euonymuses*, *Veronicas*, and *Myrtles*; a noble *Cordylone indivisa* was killed; and on a south wall, where the plants were protected during the winter, a large *Mandevilla* has gone, as well as *Verbenas* and *Habrothamnuses*, and a *Magnolia* is much browned. All our plants of *Pampas* Grass, too, are dead. The place of which I speak is sheltered, and on the limestone plain in the centre of Ireland, which rises some 200 ft. above the sea level. At Charleville Forest, some twenty miles to the south, Laurels have been in many cases killed. Those very intelligent nurserymen, Messrs. Rodger, McClelland & Co., of Newry, write to me that the winter has treated them also very badly, though their stock is so large, they will soon repair the disaster. *Laurustinuses*, *Euonymuses*, and the large-leaved *Veronicas* are killed to the ground. *Ceanothus Veitchii* has proved proved quite hardy, even as an unprotected bush in the open ground. The *Azures* group is safe. *Gloire de Versailles* is alive and, happily, breaking. Curiously enough, by the side of squares of *Laurustinuses*, of which not a vestige remains above ground, hundreds of *Dracæna australis* rear their heads, the ends of the leaves browned, but otherwise uninjured. The small-leaved *Veronicas* are all safe; *Escalarias* are dead to the ground. I hear that *Rhynchospermum jasmoides* has stood perfectly in Sussex, and *Camellias* are green and vigorous where the common Laurel is brown, languid, and unhappy. I saw this at Lord Pelham's, near Folkestone—magnificent plants covered with bloom. Still, there is no reason for despair. The actual losses will very probably turn out less than was at first supposed, and we shall, at least, know better what to plant and what to avoid.

BRINSLEY MARLAY.

St. Katharine's Lodge, Regent's Park.

The weather here (Bromsgrove) for the past eight months has been very severe. We have lost cartloads of shrubs usually considered perfectly hardy, notably common Laurel, which has behaved badly, double *Gorse*, which is quite dead, *Berberis Darwinii*, *Cotoneaster microphylla*, and many others; our *Decidars* have lost nearly all their leaves and look like deciduous trees, and even common *Yews* and *Hollies* are cruelly scarred and damaged. I have very little faith in the fruit crops hereabouts.—H. M.

The Past Winter in Ireland.—We learn that there has been great destruction of trees and shrubs in the south of Ireland. Many of the fine plants at Fota, near Cork, are killed, including the New Zealand Flax, which grew in quantity there. The variegated forms suffered less than the green kinds. The *Dracænas* and the Tree Fern (*Dicksonia*) were also killed.

Sarmienta repens.—This charming little Gesneraceous plant is one of the best we know of for growing in baskets, or suspended pans, or pots in a greenhouse. The slender very creeping stems hang gracefully over the sides, and for a long time during spring bear a profusion of bright scarlet tubular flowers, which are very showy, especially when seen in quantity, as we saw a few days ago in Messrs. Veitch and Son's nursery, at Chelsea.

LOCAL INFLUENCE ON VEGETATION.

"My garden is unfavourably situated on a clay subsoil, but this can scarcely influence to an extent so injurious plants grown under glass in soil suitable to them, more especially as the evil of which I complain is *increasing*" (p. 356). "Some of the houses have been built *fifteen years*" (p. 404). Several professional cultivators having agreed to differ about this mystery, may I be permitted to suggest that the words in italics in the above extracts contain the solution of "E. T.'s" difficulty. The glass having in the course of its long exposure to light changed to a yellowish, non-actinic tinge, and the statement that the influence first shows itself in arrested growth of the foliage would seem to confirm my conjectures. I would call the serious attention of horticulturists to the evil influence that discoloured glass must have upon plants submitted to its killing care, a point either unknown to them, or disregarded as of no importance. Another matter to which no attention appears to be given is the extremely varying quantity of actinism which we get on different days. I know, as a practical photographer, that on arid, blue-sky days, with the wind in the north and east, the power of the light is trifling compared with that which we get with a south or west wind, bringing up moisture and almost self-luminous masses of cloud; and it is not the mere moisture that makes the difference, but that ever-varying property of light, which we call actinism, that ought to obtain some attention from those engaged in forcing, if from no others.

LONDON STONE.

— May I be allowed to state that I have been in the employ of "E. T." as head gardener ten months, and that during that time I have had no interference whatever as regards the management or treatment of his plants; also that I have every requisite required for plant-growing. I can also testify to "E. T.'s" practical knowledge of plants and their requirements. I have never before experienced such difficulties in the way of plant culture as I have met with here; the plants to which "E. T." especially refers almost refuse to grow, and for what reason I am utterly at a loss to guess. Cuttings strike freely and also root well after potting, and for a time the roots remain healthy, but from want of growth they, too, become effected.—W. G.

Plants Uninjured by Rabbits.—As my place is infested with rabbits, I have made a list of shrubs, &c., not injured by these vermin, and if any one can add to it I shall be much obliged. I call certain plants rabbit-proof, but my experience, of more than twenty years, has shown me that there are individual rabbits from which nothing is safe—"dog in the manger," in fact—which, from sheer mischief, bite things that they will not eat, especially attacking what is newly planted, and going back day after day to finish the mischief, unless the plant be protected. I find the stems easily preserved by rolling loosely round them a few Briers, or even placing upright twigs of any sort round the stem, and tying them closely to it. This, of course, does not apply to the protection of the outer branches, but only to hinder them from barking the stem. I find dabbling with mud also very often effectual. My list is as follows: *Andromeda Catesbei*, *A. formosa*, and some others, excepting *A. polifolia* and *cassiniofolia*; *Aracarias*, *Arbutus* (including *Pernettyas*), *Aucubas* (when large), *Azaleas*, *Berberis* (except *stenophylla*, which is cropped at the points), *Box*, *Black Thorn*, *Butcher's Broom*, *Brier*, *Corchorus japonica*, *Cryptomeria elegans*, *C. japonica*, *Cupressus Lawsoniana*, *Chimonanthus fragrans*, *Chionanthus virginica*, *Deutzias*, *Elder*, *Euconymus*, *Heaths* (except sometimes *E. herbacea*), *Epimediums*, *Gaultheria Shallon* and others, *Helleborus*, *Hollies* (only when old), *Honeysuckles* (climbing and *Tartarian*, &c.), *Ivy*, *Junipers* (except the berry-bearing when small), *Kalmias* (of sorts, except *K. glauca*) *Ledums* (of sorts), *Laburnum* (except when small), *Laurels* (only when large), *Lilacs*, *Mahonias* (except when very small and newly planted), *Menziesias*, *Myrica cerifera*, *M. californica*, *Periwinkle*, *Podocarpus*, *Polypoda Chamaebuxus*, *Privet*, *Quercus Ilex* (*Evergreen Oak*), *Retinospora ericoides* (all of which greedily eaten), *Ribes sanguineum*, *Rhododendrons* (except dwarf small-leaved kinds, which are sometimes cropped), *Rhodora canadensis*, *Roses* (generally), *Savin*, *Sweet Brier*, *Spiraeas* (both herbaceous and shrubby), *St. John's-wort* and other *Hypericums*, *Syringas* (*Philadelphus*), *Thuja Lobbi*, *Thuiopsis borealis*, *Weigelas*, *Wellingtonia* (?), *Yews* (of sorts), the common *Taxodium*, and the upright *T. japonicum*.—M. C. D.

Alpines on Walls.—This plan of growing Alpines we saw a few days ago in Mr. Latimer Clarke's garden at Sydenham Hill, in which a wall, built slightly in a slanting position and facing south, was thickly covered with numerous *Saxifrages*, *Primulas*, *Androsaces*, and similar plants, all thriving vigorously, their only point of attachment being the narrow layer of soft mortar between the bricks. The wall is backed up with soil—in short a sunk fence or ha-ha, and this probably keeps the mortar moist.

PLATE CLXXXI.

ERITRICHIMUM NANUM AND PENTSTEMON HUMILIS.

E. nanum.—Most people are acquainted with the interesting little Forget-me-not (*Myosotis alpestris*), which inhabits the Scotch mountains, to which this, the loveliest of all Alpine gems, is a near relative, but it far excels it in the intensity of the azure-blue of its small blossoms, a colour only equalled by some of the Alpine Gentians, such as *G. verna* and *G. bavarica*. Though it has the reputation of being somewhat difficult to cultivate, a fair amount of success may be ensured by planting it in a compost consisting of finely-broken limestone or sandstone, with the addition of a small quantity of rich fibry loam and peat, and selecting a spot for it in the rock garden, where it will be fully exposed, and the roots in proximity to masses of half-buried rock, to the sides of which they delight to cling. Being always found growing naturally in stony places and continually watered by myriads of snow rills, due observance should be paid to providing it with an abundant supply of water during spring and summer, but it should be withheld in autumn. The chief enemy with which one has to contend in growing this little gem, and indeed all other Alpines which have silky or cottony foliage, is excessive moisture during winter, which causes them to damp off in a short time; in their native habitats they are covered with dry snow during that period. To obviate this some recommend planting it where an overhanging ledge protects it from rain, &c., but if such protection be not removed during summer, it has an injurious effect, causing, as it does, too much shade and dryness. A better plan is to place two pieces of glass so as to form a ridge over the plant, thus keeping it dry, and at the same time allowing a free access of air at the ends, but these should be removed early in spring. It is a native of Europe, and is widely distributed, as it is found along the whole range of the Alps from Carniola to the south of France, and it revels in the clear rarified atmosphere of the loftiest summits often as high as 10,000 ft.

Pentstemon humilis.—With but few exceptions, many kinds of *Pentstemons* that have come to us from the Far West grow from 1 ft. to 2 ft. in height, but this diminutive Alpine species, which inhabits lofty regions on the Rocky Mountains, seldom exceeds 9 in. in height. It forms compact tufts, and is remarkably free-flowering, and the blossoms, which are large for the size of the plant, present a very attractive appearance, on account of their pleasing blue colour, diffused with a reddish-purple hue. It should be planted in the rock garden in the most select spot and fully exposed, using a compost of gritty loam and well-decomposed leaf-mould, and during summer it should be copiously supplied with water. W. G.

Hardy Flowers at Kew.—Amongst the most noteworthy of those now in flower may be named the Carinthian *Wulfenia* (*W. carinthiaca*), a pretty dwarf rock plant, growing about 6 in. high, with a tuft of finely toothed leaves, from which spring flower stems terminated by a dense cluster of small purplish-blue flowers. The purple-flowered variety of *Polygala Chamaebuxus*, figured in *THE GARDEN* (Vol. XIII., p. 36), makes a charming little rock plant. Its pink Pea-like blossoms with a yellow keel are produced plentifully, and are very attractive amidst its small Box-like foliage. The Himalayan *Primula Munroi* is flowering very freely, its pure white blossoms, rising from deep green tufts of small oval leaves, being very effective, and rendering it a most desirable kind. A rare member of the same family is the Obtuse-leaved *Androsace* (*A. obtusifolia*), with small umbels of pure white blossoms with golden eyes. Another exquisite Alpine is the Pyrenean form of the Alpine Forget-me-not (*Myosotis alpestris*), of which a coloured illustration was given in *THE GARDEN* (Vol. XI., plate LXI). Nothing can be prettier than cushion-like masses of this plant, not more than 1 in. high, studded profusely with small flowers of the deepest azure-blue, with a very small yellowish eye. It is a notable fact that this Pyrenean form is far more robust in constitution than the Scotch form; as a cultivated plant, it is therefore preferable. Of the numerous kinds of *Fritillaries* now in flower, the most desirable is *F. pallidiflora*, a really handsome kind, that grows about 1 ft. high, and has rather broad, very glaucous leaves from the axils, of which large white blossoms are produced plentifully, and have a very pretty effect, drooping, as they do, so gracefully. *F. pyrenaica* is another handsome kind, the flowers of which are bell-shaped, of a vivid purple hue outside and yellow within. *Muscari compactum*, one of the newer kinds of *Grape Hyacinth*, is a pretty addition to that class of plants. It much resembles *M. neglectum*, as regards its blue-black flowers, but is larger in all its parts, more especially the foliage, which is much broader.—W.

DWARF ROCKY MOUNTAIN PENSTEMON [P. HUMILIS]

FAIRY BORAGE [ERITHICHIMUM NANUM]

GARDENING FOR THE WEEK.

Flower Garden.

Though the season is advancing, considering the necessarily low temperature of the ground through lack of sunshine, nothing will be gained by planting out tender bedding plants till there has been a few days of bright sunshine. Meanwhile, however, the plants should be subjected to the hardening-off process by placing them under the shelter of trees, walls, and turf pits, and the more tender kinds, such as *Coleus* and *Alternantheras*, must still have the protection of glass. *Calceolarias*, *Verbenas*, and *Lobelias* will stand 2° of frost; these may therefore be planted together with all hardy plants, and the putting out of the tender kinds will then be quickly accomplished as soon as favourable weather has set in. There are two requirements of especial importance as regards successful planting; the first is, that the roots be in the same state as to moisture as the ground to which they are to be transferred; and the other is, that the soil be well compressed about the roots. Beds or borders intended for small seedlings, or for plants that are to be put out without balls of earth, should be previously well watered; and if partial shade, such as that afforded by evergreen twigs, can be given, they will start into growth the more readily. Advantage should be taken of showery weather to thin out and transplant *Asters*, *Stocks*, *Phlox Drummondii*, *Zinnias*, and other annuals; also biennial plants, such as *Antirrhiums*, *Pentstemons*, *Wallflowers*, and *Sweet Williams*. In dry weather surface-stir the soil amongst herbaceous plants and shrubby borders, a process which has the three-fold advantage of destroying seedling weeds, aerating the soil, and ensuring neatness, without which no garden can be fully enjoyed. *Clematises*, *Wistarias*, and other climbing plants are now in rapid growth, and will require some little attention as to training, in order to prevent injury from high winds. One of the most telling and natural modes of training, if such it can be called, for *Clematises* is to let them ramble at will amongst a few Hazel branches in quiet and retired nooks in pleasure-grounds, associated with shrubs of any kind. This manner of growing them is most suitable. Roses, in spite of the cold, seem to be pushing very strongly, and, at present, are free from aphides and maggots; but doubtless both will shortly make their appearance, when summary measures for their expulsion should be taken by syringing with soapy water or Tobacco liquor for aphides, and hand picking for maggots—the only certain cure and, if taken in time, the quickest. —W. W.

Auriculas.—Those who are saving seeds of these will not be able to repeat the plants until July or August. We always put aside some plants from which to save seeds, which take nearly three months to ripen from the time of the setting of the blossoms. Some difference of opinion exists as to the best position of the plants when the seeds are ripening. Some fancy that they should be rather freely exposed to the sun; however, I prefer placing them behind a north wall, or in other positions where they have the sun for a few hours in the morning, and again in the afternoon when its rays are not so hot as at noon. I had a letter from one of the best growers in the north last week; he says, "Auriculas are looking well, and I intend to begin potting at once." He can only get at his plants at night, and it will take him just a month to finish potting. Saturday afternoon is a great boon to amateurs of this kind. Ordinary lovers of flowers have little idea of the shifts to which enthusiastic "specialists" are driven in order to effect their purpose. See that the loam used is not infested with wireworms; if it is, they must be carefully removed by hand-picking. Next to the quality of the loam, the drainage is most important. If a sort of delicate constitution be allowed to remain in a pot wherein the drainage has been choked by the compost working in amongst the potsherds, probably the plant will die, or, at least, become so debilitated that it will take years to recover.

Carnations and Picotees.—This week we have begun to place sticks to the stems of our plants. It is best to do this in an early stage of their development, otherwise they are apt to be broken over near the surface of the ground. If there be any green fly on the plants, remove it with a brush while the work is in progress, or it may be convenient to dust them with Tobacco-powder. If any scarce varieties be throwing out growths near the base of the stem, and that are too high up to be layered at the right season, they may now be slipped off and put into pots, placing the latter under a close hand-glass behind a north wall, where I allow them to remain for ten days or more, and then place the pots in a frame with a gentle bottom heat; treated in this way, most of them will form roots, and be stronger and better than those layered in the usual way. Seedlings will also require attention; if they are large enough to handle, let them be pricked out an inch or more apart in pans or boxes. Pay attention to watering the growing stock in pots; it has

not yet been necessary to do this in the case of those planted out in beds.

Hollyhocks.—The weather is now warmer, and plants put out early are making considerable growth; a single stem only should be allowed on each plant. Red spider does much injury to the Hollyhock in warm, dry weather; it is therefore well to see that the leaves are quite clean during their early stages of growth. Seeds sown in fine soil in the open ground would still grow strong enough to flower well next year, or the seeds would vegetate more readily if sown in pots or pans, which could be placed in a gentle hotbed.

Gladioli.—If seeds of these were sown as recommended on a hot-bed in April, the plants will now be strong, and in order to get good bulbs that will flower well next year, see that they do not suffer from want of water when in a growing state. I remove the glass lights from the frames in the daytime when the weather is fine, and replace them at night. In cold days the lights are merely tilted a little at the back; nor do I let them get rain, unless it be a warm gentle shower, which does good. A few bulbs may yet be planted for the latest bloom. Keep the hoe at work amongst those that have appeared above ground, and as soon as dry warm weather sets in give a good watering, and then mulch the surface of the beds with rotten manure.

Hardy Primulas.—I see that "A. D." comments on my notes on these last week. I never said the plants were not quite hardy; but I planted some out-of-doors ten years ago, and they gradually dwindled away. I had two or three dozens of them out-of-doors this year, and the leaves were quite disfigured by wind and rain. In a sheltered nook on the rock-work at Chiswick I saw a plant of *P. amena* looking remarkably well; but it was almost as snug as if it had been under glass. My plants are now in full beauty, and are well worthy of culture for greenhouse decoration; but out-of-doors they can only be planted in exceptional positions.

Tulips.—Beds of these are now becoming interesting even to the ordinary observer. In one bed a few hyblemen breeders are now in flower, and very beautiful they are; they contrast well with some flamed and feathered bizarres in juxtaposition to them. When one looks at the beautiful feathering on some *Tulips*, and the chaste beauty of the rose grounds, it does seem strange that they should have gone so entirely out of fashion. Their time will no doubt come round again; indeed, one grower in the north of England, failing to get a satisfactory bloom, owing to the late spring frosts, has built a glasshouse to cover his beds, and it is a treat to see the beautifully healthy glaucous foliage that has been produced under such favourable conditions. —J. DOUGLAS.

Greenhouse.

Camellias.—Where sufficient numbers of these plants exist, and are managed in a way to yield a long succession of flowers, those that were in bloom before the close of last year will by this time have made their growth, and will have formed flower-buds that will be visible, and where any of such require potting, I should recommend that operation to be carried out now, when, as I know from experience, it will interfere less with their ensuing flowering than if it were performed at any other time. If it be done in spring just as growth begins, an unavoidable injury occurs to the roots that at once seriously interferes with the tax put upon them to support, commencing shoot extension when root assistance is most required. That this damage to the roots cannot be avoided, even if there be no further interference with the ball than the removal of the crocks, will be evident, as anyone who has ever potted *Camellias* must have noticed the extremely fragile character of their feeding fibres, which, previous to top-growth beginning, are in the most active condition if the plants are in anything like a healthy state. If the potting, with its consequent disturbance of the roots, takes place now, just as the buds are formed, it has no effect in retarding the season's growth, and the buds are not sufficiently advanced to suffer through the effects of the shift, as they would be almost certain to do to the extent of falling off if the operation be deferred later, and there is yet plenty of time for the roots to recover the breakage to which they have been subjected, and to get fairly established in the new soil, and be in the most favourable condition for supporting the expanding bloom when the time for its opening has come. From these observations it will be seen that where *Camellias* are managed in a way to give a succession of flowers, the potting cannot be carried out at any particular season, but should be performed as the plants in succession approach the bud-setting stage, already indicated. At the same time it may be well, perhaps, to inform beginners that *Camellias* will thrive with considerably less root-room, in proportion to the size of the tops, than many other plants, and that too large pots or tubs, especially when the plants are not in a vigorous state, are the most likely means of bringing about an unhealthy condition. I have often seen *Camellias* pointed out when somewhat weakly as requiring more root space when the opposite course should have been pursued, and

when the best way of improving them would have been to have removed a portion of the soil, replacing it by fresh material, and putting them in smaller pots or tubs for a time. They never should be repotted oftener than can be avoided, as they may be kept in a healthy growing state by the use of manure water, provided this be given at the proper time to be effective, which is immediately before and whilst the shoot growth is going on. It is no uncommon occurrence to hear an opinion expressed that liquid manure is of no use to these plants, and, from what I have observed in the matter, I very much doubt if it is, unless applied at the time above mentioned. Even in the case of plants that are fairly strong, and with sufficient root-room, I have found that whilst growing there is nothing more beneficial than liberal applications of soot-water given in a clear state; it seems to agree with Camellias better than with most other plants; it strengthens the growth, gives a deep lustrous green to the foliage by which the appearance is much improved, and has a powerful influence in ridding the soil of worms. As to soil, some growers prefer loam, others peat. Where loam of good quality can be obtained, the plants will generally have more disposition to bloom in it than in peat; but in the latter the growth is freer, the foliage larger, and of a more pleasing colour. Whichever is used, the pots must always be well drained; sufficient sand must be added to the soil to insure porosity, not only at first, but afterwards, and in the potting the soil must be compressed, so as to make it thoroughly solid. The latest flowered plants will now be making their growth, which must be encouraged by a moist, comparatively close atmosphere, with more shade than is necessary for that portion of the stock that made their growth before the sun had so much power.

Azaleas.—As the latest flowered amongst these go out of bloom, all seed-pods should be immediately picked off and the plants placed in a house or pit, where a warm, genial, moist atmosphere can be kept up, giving air in the morning before the temperature has risen too high, and shutting it off early enough to enclose plenty of sun-heat. At the time of closing syringe thoroughly—not a mere sprinkling, but a good drenching—getting the water to the under surface of the leaves on all sides of the plants; by this alone can thrips and green fly be kept in check, and where these pests are found to exist, means should at once be taken to destroy them by dipping or syringing with Tobacco-water or fumigating. The latter is the quickest way, but I do not like resorting to it, as it often takes a stronger application of the smoke to kill the thrips than the leaves will bear. Any premature loss of foliage, either through this or injury sustained from the insects in question, is certain to show itself in the weakened condition of the plants, through which cause, more than all others, is directly attributable the unsatisfactory state in which Azaleas are often met. The earlier bloomed plants will now be in a condition to pot in the case of those that require it, but such as flowered later should be left undisturbed for three weeks or a month yet. Azaleas, like Camellias, are best without too much root-room for several reasons, one of which is, that if placed in large pots before they have attained a corresponding size, a time comes when the soil gets so permeated with roots as to necessitate still more room, which makes them inconvenient to move about and is not necessary, for by the use of concentrated stimulants, such as Standen's manure, which I have found far the best for Azaleas, using it from the time the plants were in small pots upwards, large specimens can be kept in a vigorous, free-growing, satisfactory flowering condition, with much less root-room than many subjects need. Keep the plants well up to the glass, and use no shading more than is necessary to prevent the leaves getting absolutely burnt; by being thus exposed to the sun, they will acquire a solidity and substance that will enable the plants to retain them in much larger quantities through the winter than when grown under the weakening influence of subdued light.

Coleus, Centaureas, Humea elegans, &c.—If a number of Coleus of the most effective varieties be grown in small or medium-sized pots from cuttings struck each spring one of the most serviceable purposes to which they can be put is for use in greenhouses and conservatories during the summer and autumn until the temperature becomes too low for them to preserve their character. If a sufficient quantity be put now in 7-in. pots in good ordinary soil, and grown on in a cool stove or intermediate temperature, kept well up to the light, and stopped so as to enable them to branch out without any attempt to induce the low, flat form which these plants are too often made to assume, from their naturally rapid growth, they will, by the middle of July, be large enough for decorative purposes such as those for which they are intended. There are numbers of plants generally used as bedding subjects that are very serviceable potted on in like manner, notably the white-leaved Centaureas, such as *C. argentea*, *ragusina*, and *gymnocarpa*. If a few of the stronger examples of these raised from seed or cuttings be placed in 6-in. or 7-in. pots, and grown on in a frame or pit until the middle of summer, they will be of great use for placing amongst flowering or higher-coloured-leaved plants in

greenhouses, halls, or conservatories. When well managed, few plants have a more elegant appearance than the old *Humea elegans*, especially in large conservatories, but to have it in good condition it must not be stinted for pot-room, never allowed to want for water, and the under surface of the leaves should, from time to time, be examined in order to see that they are not affected with green fly or red spider, to both of which they are very subject. The bedding *Chamaeopsis Cassabona* is likewise well adapted to be used in the same way; also the large *Echeveria metallica* and the variegated *Coprosma Baueriana*. The last is a plant of comparatively slow growth, and one which is well deserving of cultivation in pots for conservatory decoration; it will succeed in either peat or loam, but in peat the foliage generally has the cleanest and brightest appearance. For standing on shelves or in positions where there is not room for large pots, a few of the best flowering *Lobelias*, especially the lighter-coloured varieties that have a free habit of growth, will be found very useful during the autumn. It may be said that some of the plants just named are common, and that their legitimate position is in reality in the open ground, but they are so distinct and well adapted for use in the way here indicated, that they afford a pleasing variety when it is most needed in greenhouses and conservatories.

Veronics.—The late-flowering varieties of *Veronica*, of which *V. Andersoni* may be taken as an example, are indispensable for blooming through the last months of the year; they are so manageable that they will flower in either a small or large state, according to the size of the structure in which they are required, or the inclination of the cultivator; but the condition that they will be in at the time required depends upon how they are treated now. They may be either kept in pots plunged through the summer, or planted out in free open soil and then lifted in autumn. For such as are wanted in a large state, retention in pots will probably be the best way, provided they are regularly attended to with water, from a deficiency of which plants thus turned out often suffer. If that be likely to occur, it is better to have them planted out where the roots, to a certain extent, can make shift for themselves. In the case of plants struck in winter or during this spring, I should give a decided preference to planting them out, as they will probably attain double the size they are likely to reach in pots. A good open situation should be chosen for them, and all plants of a similar description, away from trees or other influences likely to draw them up weakly.

Tree Carnations.—These indispensable winter-flowering subjects, through the press of other matters during summer, do not always get the attention which they need. To get spring-struck stock up to a useful size before autumn, it must have timely moving into pots large enough to admit of its full development; at the same time it is not well to give it more root-room than is necessary. The principal thing to avoid is allowing the plants to remain in the little pots which they occupy too long, by which means the roots get into a stunted condition, and the best of the growing season is over before they attain any size. Plants that have bloomed and that were shaken out and repotted will require constant attention as regards water, as the pots get full of roots, and sufficient support by sticks and ties should be given to keep them from falling about in an untidy way. In doing this, however, avoid compressing them into that broom-like form to which they are sometimes subjected, and which has a direct tendency to aggravate the natural disposition which some of them have to spire up weakly. On the appearance of green fly, dip or fumigate; the former is frequently the most effectual, as on these plants aphides seem more tenacious of life than they do when fed on the juices of some others.—T. BAINE.

Hardy Fruit.

While the weather remains so uncertain one can only reiterate the necessity there still, unfortunately, is to guard wall fruits against cutting winds and frost. Notwithstanding the unfavourableness of the season, the fruit prospects here continue excellent; Apricots are good; Peaches are all that could be desired; Pears, Plums, and Cherries the same; small fruits heavy crops. Apple blossoms, though not yet open, were terribly injured by the frost on the morning of the 10th, when the thermometer fell to 24°. We may now reasonably hope that the end of the winter has been reached, but till there is a decided change let the breastwood on Pears, Plums, &c., remain intact, as this will give some little protection to the tender fruit, and its removal at this early stage of growth, though desirable, is not imperative. No quarter should be given to aphides, for if not attacked as soon as perceived, at this season they soon destroy the prospects of a crop of Peaches, Cherries, and Plums, all of which are peculiarly liable to be infested by them. The cheapest and most effectual remedy is soap-suds, applied either by means of the syringe or garden engine; since we have applied these, we have never remarked any evil consequences, such as are likely to follow the application of some at least of the many decoctions that are offered for

their destruction. Curled and blistered Peach leaves should be picked off, and if mildew appears dust the affected parts thickly with sulphur. The surplus fruit of Apricots should now be picked off; Peaches will also require the same attention, but at present these should be thinned but sparsely, and disbudding should now be completed. Any injury that Strawberries have sustained consequent on such a protracted winter is, after all, more apparent than real, as they are now throwing up their flower-stems as strongly as ever, and though the greater part of the old foliage has decayed, the growth of the young leaves seems to have been the more vigorous in consequence, and there is now promise of a good Strawberry season. Strong plants that have thrown up a number of flower-stems should have the weakest of them removed, more especially when fine dessert or exhibition fruit is desired. If not yet mulched, such an operation should no longer be delayed, as in the event of dry weather setting in it will prevent the necessity for watering, and in the meantime will nourish the plants. Plant out recently forced plants, and for the present, having a view to autumn fruiting, keep the flower-stems picked off. Thin out any unnecessary shoots or suckers of Raspberries, retaining about four of the strongest to each stool. Raspberries are free feeding and moisture-loving plants, and soon suffer from drought; therefore the ground about them should now be covered with good manure, which will serve both purposes, and repay the labour bestowed by producing finer fruit. Where grafting has been done persistently rub off all shoots that spring from the stock, and occasionally examine the grafts, making good any injury that has happened to the clay from frost or drought.—W. W.

THE FRUIT GARDEN.

VINE FAILURES.

THE irregularity with which "E. D. T.'s" Vines (p. 385) are breaking is, no doubt, owing, as he surmises, to the winter dressing the stems received, for if the solution applied were at all strong, it would be sure to destroy or injure the buds, and damage the bark as well. More harm is done to fruit trees by the use of insecticides when they are in a dormant condition than most people imagine, and the failure of crops arising through it is generally attributed to other causes instead of the right one. I have known instances of Peaches and Nectarines suffering so much from a strong winter dressing as to cause them to shed the whole of their buds, and so cripple their health that they were a long time before they recovered again. Vines will stand more, but the practice of annually barking and painting them over is a bad one, as it serves no useful purpose, and takes from the plant that which Nature intended as a protector to the inner rind, a part that should not be needlessly exposed, for if it is, the light and air acting on it causes contraction, which greatly impedes the flow of sap and the swelling and growth of the wood. I do not see how it is possible that Vines which have hitherto been in such a satisfactory state as those "E. D. T." is concerned about appear to have been can have failed all at once through anything having gone wrong at the roots, unless they are partly eaten by the larvae of any insect, such as those of the Otiorhynchus, figured in THE GARDEN a short time ago, and which are most destructive to Vines; so mischievous are they, that they eat long furrows in the main roots, and in places nearly divide them, thus cutting off the principal channels for the flow of the sap, and leaving their feeders beyond utterly useless. Some years ago I had a border sadly infested by these grubs, and before we could get rid of them they did a great deal of injury, and had it not been for renewing the soil, it is quite likely we should have been plagued with them yet.

Another likely cause to affect the Vines in question is that they may have fungus generated around their collar, a thing that frequently happens when they are planted inside and kept dry, as is generally the case if the stems are wholly under cover, as then the decomposing bark seldom gets wetted through, and is therefore just in the condition favourable for the spread of the mycelium that does so much harm to vegetable life. There is one thing about this, its presence may be easily detected by making an examination of the suspected part, and if the fungus is there it will be apparent by the whiteness of the inner portions of the bark, besides which it always gives off an offensive odour. Minute, and of little consequence as such a parasite may appear, it paralyses the whole action of plants, and not only quickly throws them out of health, but, after a time, destroys them altogether. Being out of sight, such an insidious enemy is seldom suspected or even thought of; but I am of opinion that more Vines and fruit trees suffer from it than from any other malady. Should those belonging to "E. D. T." turn out to be so affected, I would recommend the whole of the outer loose bark about the collars to be removed, and that part to be scrubbed with soap and water, and

afterwards coated with thick liquid lime and clay painted on by means of a brush. This dressing will destroy all the fungoid growth it comes in contact with, and will not in any way injuriously affect the Vines; but to keep them free from such a scourge in future, attention should be given to see that the border at the particular part where the Vines stand does not get into a too arid condition, or have any decomposing vegetable matter, such as leafy manure, lying long on its surface. If the roots of the Vines be healthy, and the injury results from the winter dressing, the best way will be to run up fresh young rods from near the bottom by making choice of the shoots most conveniently situated, as the chances are that the old ones will never break regularly again, owing to the spurs having perished. The house may then be refurnished and the Vines in profitable bearing again in less than half the time it would take if replanted; for, under the most favourable conditions of growth, young rods should not be allowed to carry a full crop under three years, or the strain will tell on them afterwards. The Vines being planted in the way "E. D. T." describes, that is, immediately in front of the arches and close to the wall, are in as favourable a position as it is possible for them to be, and they are sure to find their way out without any coaxing or disturbance; and, as the border appears to have been well prepared, the wisest course seems to be to let them alone.

Without an examination it is almost impossible to say what is the real cause of their having gone amiss; but these conjectures may help to elucidate the mystery and be of some assistance in getting them right again. As failures and the knowledge of what has led to them often do more to benefit others than recorded successes, perhaps "E. D. T." may be kind enough to inform us at some future time what discovery he has made with respect to his, and the means he took to remedy the same. S. D.

EXPOSING STRAWBERRIES TO THE SUN.

NOTHING tends so much to deteriorate the flavour of Strawberries after being gathered as to leave them exposed to the sun, the heat from which at once sets the juices contained in them in a state of fermentation, and converts the saccharine matter into something little better than vinegar. The same action takes place, though in a less degree, with such fruit as Peaches and Nectarines, and does not in any way improve any other fruit after being plucked from the plant, as even in the case of Apples and Pears the tendency it has is to cause them to shrivel instead of allowing them to ripen properly. The cooler and drier fruit can be kept when gathered till used the better, as that is the only way to preserve its true flavour, and another matter of great importance connected with it is to see that it is not bruised or damaged in the handling, either when picking or dishing it up. I have seen servants when engaged at this latter work take hold of Strawberries between the thumb and finger, and handle them with no more care or thought to all appearance than they would use in the case of an uncooked Potato, and the same with Grapes, which they rub all the bloom off; while as to Peaches and Nectarines, the bruising which they receive, unless eaten immediately, soon causes them to become decayed. This indifference on the part of those who have to dish fruit is no rare occurrence, as most gardeners can testify, but to know that it is so is very provoking, as the productions on which they pride themselves seldom get placed before their employers in the condition they ought, and the result is that they are often subjected to blame through the shortcomings of others. Not only are Strawberries injured by being exposed to the sun after being gathered, but the same thing happens to those in pots if subjected to the full solar rays after this season, the great heat being more than the fruit will bear, and so trying is it that I have often seen the seeds roasted, as it were, and the Strawberries containing them quite browned and completely dried up. This is sure to happen if the plants get the least dry and the fruit thereby checked in its swelling, but as a safeguard where late ones are grown it is always advisable to turn their backs to the south and let the fruit droop away from the sun, so that it may in a measure be screened by the foliage. It will be found, if this is done, that the fruit will not only swell faster and grow considerably larger, but that the quality will be altogether finer, although a certain amount of sun is necessary, but much at this time of year is a thing to be guarded against, as it is a frequent cause of rendering the late lots of these useful fruits inferior to those gathered early in the season. In picking Strawberries for use, they should always be got early in the morning, that is, before the sun shines on them, and before the plants receive any water, as this is quickly conveyed to the fruit, which it makes flat and insipid in flavour. S. D.

Pot Strawberries and Frost.—I have maintained in THE GARDEN and elsewhere at different times that pot Strawberries might be exposed to severe frost for a long period without suffering the

slightest injury or having their fruitfulness impaired when they came to be forced, an assertion which has been so emphatically contradicted by others. The examples of Strawberries furnished to THE GARDEN office this week by Mr. Muir should, however, set the question at rest, I think. These Strawberries (about a dozen large, richly-coloured fruit to a 3-in. pot), we are told, are from plants that have, during all the last severe winter, stood unprotected and "hard frozen."—J. S. W.

STRAWBERRIES FOR MARKET.

I AM quite willing to acknowledge that Mr. Cornhill (p. 402) knows more about market gardening than I do, nor do I doubt the ability and success of market gardeners generally in the culture of fruit. I believe that we private gardeners have learned much from them; but the question between him and me relates to his assertion that Vicomtesse Héricart de Thury was of "little use to market growers," who, he further adds, are "obliged to confine themselves to such varieties as are of delicate constitution" if they desire to get a good price for their fruit. This is a definite enough statement, and is what I undertook to controvert from the papers of "C. W. S.," whose impartial and disinterested statements on the subject, and the evidence of my own eyes, I choose to accept as being probably nearest the truth. In THE GARDEN of April 12 he mentions Sir Charles Napier and Vicomtesse Héricart de Thury only as the most popular for market purposes, and we have Mr. Cornhill's word for it that the latter is an inferior kind; and I shall be surprised if many gardeners who know much about Strawberries will coincide in describing "Sir Charles" as anything but a second or third rate kind of vigorous constitution. Allow me also to inform Mr. Cornhill that I do not confound forced with out-door fruit, which he admits is gathered as soon as it is coloured, and for the same reason, probably, that forced fruit sent to market is gathered in the same state. I spoke, however, of Strawberries in April, a season when out-door crops are not fit for market, I imagine, and those that I tasted were offered at 15s. or 20s. per lb. retail, if I remember rightly. As to the assertion that Sir Charles Napier can be grown so "as to be almost as rich and luscious as a British Queen" under glass, I can only say that I doubt the fact. I admit that Strawberries can be grown to as great perfection under glass, under favourable circumstances, as out-of-doors; but so that they can be improved to the extent of converting a Sir Charles Napier into a British Queen, is surely seeking to tax one's credulity too far. Sir Charles Napier is a favourite kind with market gardeners because it is a sure grower and bearer, and produces handsome, if not very good, fruit. As regards his asserting that Black Prince does not pay for the labour of watering it, I can state that two years ago, when we had a surplus of this kind, I sent a quantity of it to the Manchester market, and in competition with the London-grown fruit which is also sent there I received for the first lot 20s. per lb., for a similar quantity the week following, 15s. per lb.; and the next week, 10s. per lb. This was in April, when forced Strawberries were, comparatively speaking, plentiful. In the same town, and at the same time, a private buyer gave 25s. per lb. for the same kind. I can vouch for these facts if needful, and if such prices will not pay for watering, I would ask Mr. Cornhill what he considers a commonly remunerative price for the best he can produce at the same season? This year about the middle of April, Covent Garden prices were given at from 4s. to 10s. per lb. Within the present month of May I have seen Black Prince Strawberries from a private garden sold in Manchester for 6s. per lb. to a fruiterer who had his window full of London-grown Sir Charles Napier of fine appearance, but far behind the fine black gloss on berries of the "Prince" which were sent to the market just to fetch what they could, the market day being over, and the shops supplied.

J. S. W.

THINNING GRAPES.

No one can tell exactly what would be a reasonable crop for a Grape Vine to carry without knowing something of the age and strength of the Vine; a pound per footrun of rod may be a reasonable crop for a healthy Vine on the average to produce; and something may be done in feeding in critical times, such as the stoning period, to enable a plant to bring to perfection a heavy crop. But plants will not maintain their health long if overdone with stimulants, therefore the safest plan to pursue is to find out the limit of production, and not exceed it. If it be necessary to form a correct estimate of the bearing power of the Vine before deciding as to the number of bunches it shall be permitted to carry, it is still more so before thinning out the berries, as some Vines will produce berries half as large again as those of others, and that, too, independently of the skill brought to bear upon their cultivation. Take the case of the Black Hamburg—still the most useful and most popular variety

grown; there is considerable variation in the size of the berries, even when the Vines are receiving the same treatment, often, indeed, in the same house.

The sooner Grapes are thinned after it can be seen which berries are taking the lead the better, cutting out the small berries, as some of these may be imperfectly set. At any rate, those that take the lead generally keep it, and a sufficient number of such berries should be left to form compact handsome bunches. With some loose bunched kinds, such as the Barbarossa, it is a good plan to reduce the bunches a little, by cutting off their extremities. It is not easy to say how large a proportion of the berries should be cut out; in fact, without seeing the Vines it must be mere guess work, but at least two-thirds, and, in some instances, the large-berried kinds, as Buckland Sweetwater, Madresfield Court Muscat, &c., may be thinned more severely, but it is best to go over them a second time unless one is quite sure of the size which the berries will ultimately reach, as it is not pleasant to contemplate bunches lank and loose from too severe thinning. To thin Grapes well requires considerable judgment, as well as knowledge, of the strength and constitution of the Vines, and this can only be acquired by experience, accompanied by careful observation. The berries in thinning should not be touched with the hand. With a small smooth stick in one hand, and the scissors in the other, the bunch can be manipulated with ease without touching a berry. Grapes that are intended for late use should be thinned more than would be necessary if they were cut as soon as ripe; and large bunches should be well thinned out in the centre, or the moisture will lodge in the bunches and induce early decay.

E. HORDAY.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Grapes from Vines Struck from Eyes the Same Year.—May I trespass on your pages to say farther in reference to this subject that I sent Mr. Henderson, of Thoresby, the paragraphs from THE GARDEN by Mr. Groom and myself, in case Mr. Henderson might have overlooked the matter, and have received the following reply: "Of course Vines can be fruited the same year in which they are struck from eyes, and you can make any use of this letter you like. The plan succeeded with me. I adopted it when our houses were all new, as you will remember, and when our permanent Vines were only growing, and, under similar circumstances, I should resort to the same plan again, and get good average crops of Grapes from the Vines." From this it will be perceived that "the possibility of getting anything worth calling a crop," as Mr. Groom expresses it, is placed beyond a doubt, and that on some occasions the plan may be well worth adopting.—J. S. W.

New Plan of Filling a House with Vines.—Mr. Simpson (p. 324) may suppose that the practice which he describes of running a cane up the full length the first season and allowing it to remain in situ, but in this he is mistaken. I have tried the same plan more than once, and have much often seen others adopt it, but the result is the reverse of any gain, for there is always a disposition in the case of Vines so treated for several years to push an excess of vigour into the spurs towards the top, and to leave the lower ones proportionately weak, independent of the most careful management in getting them to break the first season. Mr. Simpson says the usual way is to cut the first season's growth down to the bottom wire at pruning time, and during the next few years to leave a few feet of wood every season until the Vine is furnished, a practice which takes from five to six years according to the size of the Vinery. This seems slow work, and if Mr. Simpson is satisfied with furnishing a house at this rate, no one else need complain, but it would be much too slow for most people. The practice which he imagines to be new, and that which he describes as the usual course followed, are two opposite extremes, midway between which most people, who have any claim to being successful Grape growers, would steer.—T. BAINES.

—Allow me to state that Mr. Simpson's plan of filling a house with Vines is not new. Several houses have been planted on the same plan about Bishop's Stortford, and with such good results, that more houses have been planted and filled and managed on the same plan. Amongst them I may name a span-roofed Muscat house about 100 ft. long.—W. T.

Rapid Pine Growing.—Permit me to ask "M." (p. 403) if he would kindly state whether the Pines which produced such rapid and excellent results were planted out in the pit or confined to pots, and what the variety was. In list 4 he states that from a pit planted with rootless suckers on February 7, 1878, fruit was cut in succession from July 6. This, according to the list, shows excellent results in the short space of five months; whereas, under the general mode of cultivation it takes about eighteen months. Is there any mistake in the statement, or is it a fact?—E. C. P.

ROSES.

ROSE BORDERS.

A Rose border, to be worthy of its name, should furnish Roses at least half the year through. To accomplish this, resort must be had to all classes, and the best result will be obtained by choosing the freest blooming varieties in each. Whether the plants should be standards or dwarfs seems almost immaterial, excepting as a matter of individual taste or surroundings. Dwarfs, especially those on their own roots, are generally considered more elegant and natural, and have further the advantage of producing their flowers in greater quantity, and in a manner that renders them more agreeably effective. Certain sorts, also, thrive well as dwarfs, but make very indifferent standard plants.

Some of the earliest Roses that grace an English summer are the Briers, the best of which are the Persian Yellow and Harrisoni, together with the unique Copper Austrian, which should be in every mixed Rose border. Following closely on these are the miniature Provence kinds, the best of which—De Meaux and Spong—being dwarf in growth as well as small in flower, are most suited for the front row or for edging. About the same time as these the various Moss and Provence Roses begin to open, and are speedily followed by such gorgeous summer bloomers as the Damask, Madame Hardy, Madame Soetmans, and Ville de Bruxelles; the alba—Félicité (Parmentier), Madame Audot, and Madame Legras; the French or Gallica—Blanchefleur, Cynthia, D'Aguesseau, Cillet Parfait, and Village Maid; and the summer

A Rose Border.

flowering Hybrids—Charles Lawson, fulgens, Madame Plantier, Chéné-dols, and Paul Ricaut. By the time these are on the wane we have the Hybrid Perpetuals in full beauty, and as they fade we may still cut Roses in profusion far into the autumn from such beautiful kinds as the Bourbons—Queen, Queen of Bedders, Souvenir de la Malmaison; the Noisette—Fellenberg, Coline Forester, Bouquet d'Or, Rêve d'Or, and Triomphe de Rennes; the China—Cramoisi Supérieure, Ducher, Fabvier, Mrs. Bosanquet, and the ever-blooming common pink monthly Rose; whilst such Tea-scented varieties as Safrano, Marie van Houtte, Sombreuil, Jean Ducher, Marie Guillot, are sufficiently hardy to withstand the cold of an ordinary English winter. Other Tea-scented Roses, such as Gloire de Dijon, Madame Berard, Madame Trife, Belle Lyonnaise, and probably the new Reine Marie Henriette will also give fine crops of autumnal blooms, but require training in a special manner. The main shoots should be but slightly shortened in pruning, and bent to the ground and there secured to pegs. The laterals should be spurred back in a similar manner to that in which Vines are treated, and will be found to produce a fine lot of flowers, many of them also making sufficient growth to be treated as main shoots the following year. Roses of this class should, however, be planted sparingly, unless space be of no consideration.

If the Rose border by chance be backed by a wall with a southern exposure, the season for Roses may be accelerated by almost a month, as certain of the Tea-scented and Hybrid Petepetal kinds will open their flowers in an ordinary season in such a situation in May, and such a wall would offer a fine opportunity for cultivating such distinct and beautiful varieties as the Banksian Roses, white and yellow,

the Macartney, single and double, Fortune's yellow, and the old Rosa sulphurea, sometimes called the Burghley Yellow.

The Rose border should be planted in the autumn, excepting the Tea-scented and China varieties, which are best left till spring. Pruning generally should be done in March, the tenderer kinds a month later. The plants should be mulched with short manure in autumn, which will help them to resist the winter's frost, and this will be dug in in the spring; a second mulching of long manure in summer, if the weather be dry and hot, will be beneficial. Many of the vigorous-growing Roses amongst the summer Roses—the Hybrid Perpetuals and Noisettes—may be pegged down to advantage, and be thus made to cover more ground and give a finer display of flowers.

Waltham Cross.

A. W. PAUL.

INSECTS HURTFUL OR USEFUL TO THE ROSE.

THE GARDEN ANT.—The garden ant, which belongs to the Order Hymenoptera, does great mischief to Rose trees either by forming ant-hills at the foot of the plant, or by constantly walking backwards and forwards on the branches and young shoots. Their presence is always a sure sign that aphides or kermes are not far off; by destroying these insects we put an end to the visits of the ants. We may, however, attack them in a more direct manner. If we place amongst the branches of the Rose tree several small vials half filled with water mixed with honey or sugar, the ants, being attracted by the mixture, will fall into the liquid and be drowned. To destroy an ant-hill at the foot of a Rose tree, we must turn up the soil and sprinkle it with flour of sulphur. If the ant-hill is at a distance from the Rose trees it must be laid bare, and a number of little conical packets of flour of sulphur placed in the middle and lighted. As soon as they have half burnt away the soil is returned to its place. The ants are destroyed by the sulphurous acid penetrating the soil, which also prevents any of those which are outside from returning to carry off the larvae. Ant-hills may also be destroyed by watering them with boiling water.

THE ROSE SAWFLY.—The Rose sawfly (Hylotoma Rose) is an insect which Rose-growers know only too well by the mischief they do to the young shoots. The characteristics of the Rose sawfly are a yellow head, in the form of an elongated square, bright whitish eyes, club-shaped antennae smooth and without joints, and four transparent wings with thick nerves. The two upper wings are placed close to the breast, the two under ones a little lower down. The six feet are marked with round black spots. The abdomen is of an orange-yellow, and is composed of nine rings. The lower extremity of the abdomen is split in the under portion, allowing the saw to be thrust in and out. This saw, which is formed of a horny substance, is flat, and measures 0.4th of an in. in length, by 0.16th of an in. in width. The Rose sawfly makes its appearance from the 15th of July to the end of August, at which period it lays its eggs. It has a heavy flight, and is easily caught, especially when it is at work on a young shoot. When about to lay its eggs it fixes itself against the rind of a young shoot, with its head downwards, and by means of its saw it cuts into the rind and deposits an egg. It then moves a little lower and begins again, raising between each egg a kind of partition made out of the fibres of the bark. It leaves in each shoot on an average about twenty eggs, although in some cases we have observed as many as fifty. These eggs are placed at a distance of 1.16th of an in. apart, and contain a young larva. At the end of about ten days the larva becomes visible under the shell, and may be readily distinguished by its black head and eyes, and its six little feet marked with black spots. When first laid these eggs are 0.04 of an in. in diameter, but at the twentieth day they will have increased to 0.06 of an in. They now become of a slightly dull yellowish colour and the young larva is hatched shortly after. Each of the flies lays a batch of eggs in two and sometimes in four of the young shoots before taking its departure. Like most other insects, its purpose in life having been accomplished, it dies almost immediately, its dead body being frequently found exactly under the spot where it had laid its last batch of eggs, as we have frequently observed for several years past. It is always on Rose trees in full bearing that this fly prefers to fix itself, and, by an admirable display of instinct, lays its eggs an inch or two from the top of the young shoots, so that its progeny may have soft and tender leaves to feed upon. In addition to this, we have noticed that the sawfly gives a transverse saw cut to the rind of the shoot, just below where its eggs are laid, so that they may not be covered over with the ascending sap. We may easily detect the presence of the Rose sawfly by noticing the curved form attained by the shoots in whose rind the eggs have been deposited, or after some five or six days, by the rind having turned black, without the growth of the shoot having been interfered with. The eggs are hatched about the twentieth or twenty-fifth day, and the young larvae continue to be produced for three days afterwards. At the time of hatching they measure 0.12 of an

inch long, and are of a dull white colour, especially on the body. The shell or cocoon of this egg remains in the incision of the rind. The young larvæ soon spread themselves over the young leaves of their native shoots, which they attack at the edges, leaving nothing behind but the veins. At the end of a few days, the different parts of the body begin to assume their natural colour, the head becomes black in company with the six feet, and the skin of the body is marked with small black spots. They increase in size at the rate of 0.2 of an inch in nine days. After the twentieth day the larvæ measure a little more than $\frac{1}{4}$ in. by 0.06 of an inch in diameter. The head becomes yellow with two black eyes. The mandibles turn brown, and the three pair of feet of a pinkish-white, as well as the false feet and the under side of the abdomen. The skin of the back, which is of a beautiful green colour, is marked longitudinally with yellow and black spots. The false feet are provided with a number of silky tufts. About this stage the larvæ remove to a lower portion, where they find more substantial food in the mature leaves of the Rose tree. As soon as the larvæ have reached two-thirds their natural size they cast their skins, and assume a much brighter colour. Taking advantage of the night dew, which soak through their skin and soften it, they begin to cast off their exuvia, beginning with the head, and by repeated wriggings and drawing themselves backwards and forwards, they gradually slide the old skin from ring to ring, finally casting it off when it reaches the extremity of the abdomen. At this period the larva appears of an even colour, that is to say, the different parts of the body appear to have left their proper colours in the skin which has been cast off by the insect, but in about a couple of hours the light acts on the skin in some peculiar way, and, as if by enchantment, the colours come out more brilliantly than ever. This change generally takes place at sunrise. At the end of about thirty days the larva reaches its full size, its length being nearly $\frac{1}{2}$ in., and its diameter a little more than 1-10th in. It now drops to the ground by a thread which it secretes itself, and penetrates the soil to the depth of from 1-3rd in. to $\frac{1}{2}$ in. It now spins a kind of cocoon with very close meshes, so as to protect the coming chrysalis from the damp. This cocoon, which is about $\frac{1}{2}$ in. long by $\frac{1}{4}$ in. thick, is of a yellowish-grey colour, with irregular, round meshes, and crossed by extremely fine fibres. If this first envelope is not sufficient, the larva constructs another with much finer threads outside the first one. We have torn asunder one of these cocoons, which are very strong in their texture, and we have found the larva inside curled round with its head and tail together. We have also noticed that one-third of the length of this cocoon is empty, so that there may be room for the chrysalis to change into the perfect insect, as well as for the larva to be able to move about while engaged upon its work. As soon as the Rose sawfly has finished its cocoon it is slowly transformed into a chrysalis, which, at the proper season, gives birth to the perfect fly, which appears in May or June, and gives rise to a new generation, as has already been described. These flies are very easily caught when they first appear, when large quantities of them may be destroyed. The most rational mode, however, of getting rid of them is to cut off the bush shoots upon which the eggs have been laid and burn them immediately.

THE COCKCHAFFER AND ITS GRUB (MELOLONTA VULGARIS—Fab.).—The perfect cockchafer is familiar to every one, but few know the extent of the ravages committed by the larvæ of this insect generally known as the white worm. It lives in the earth for three years, and during that time it is calculated that in France alone it destroys crops of various kinds of the value of £40,000,000 sterling. Other varieties of the common cockchafer, such as *Melolontha hippocastane*, *albida*, *equinoxialis*, *solsialis*, and *estiva*, are also very destructive in certain localities. At Ivy, near Paris, in 1864, the Grass plots and lawns of that locality were almost entirely destroyed by a white grub of a much smaller size than that of the common cockchafer; 150 of these grubs were gathered in a single square yard. Great attention ought, therefore, to be paid to lawns and Grass plots in the vicinity of Rose plantations, so as to keep them free from their destructive larvæ. They generally make their appearance towards flowering time, and never before the leaves have well advanced towards maturity. They do not appear all at once; the accidents of locality and temperature will advance or retard the transformation of the grub into the perfect insect, so that there may be an interval of as much as a month between the appearance of the first and last batch. If the weather turns cold after the first comers have made their appearance they will return to the galleries which they have dug for themselves, or else they will dig new ones if the old ones have become filled up. No sooner has the cockchafer unfolded its wings for the first time than it alights on the leaves of the trees upon which it feeds. At the dawn of day, and during the early part of the night, and often in the middle of the day, when the sky is overcast, this insect may be seen flying backwards, and forwards. Its flight is heavy,

irregular, and undecided, and it rushes blindly against any objects that may be in its way, falling heavily to the ground, from which it soon rises into the air once more and resumes its flight until it is again knocked down. It begins to breed at about the end of April or the beginning of May. The cockchafers which begin breeding so early are those which have lain dormant all the winter, owing to their having undergone a later transformation either from cold or some other retarding cause. We often see females of the former year flying about as late as the end of June. The male cockchafer, it may be mentioned, is a polygamist. The female when laying time approaches drops to the ground in the neighbourhood of some plants, the roots of which will furnish succulent food for the young larvæ. Once in the ground the female digs a hole, 3 in. to 6 in. deep, at the bottom of which she deposits some seven or eight eggs. During the day she leaves the hole in search of food, and lays a fresh batch of eggs in another hole a few days after the first, frequently on the top of her latest-laid eggs. On an average the female cockchafer lays from sixteen to twenty eggs, which are suspended in groups of seven or eight, which may be found during July at the foot of the Strawberry and other plants. The egg of the cockchafer is white, of a regular oval form, and is about 1-10th of an in. in length. The larvæ are hatched about fifty days after the eggs are laid, that is to say, about the beginning of July. When fresh from the egg the larva is about 0.2 of an in. long, and 0.04 of an in. in diameter. In colour it is of a dirty white, the head and feet being of a pale bright yellow. The mandibles, which even at this early stage are sufficiently formidable, are black. At the end of a fortnight it has grown to nearly twice the size, and the intestines filled with blackish matter become visible. When first hatched the larva feeds on the roots which are nearest to its birthplace. These larvæ live together in groups until the month of September, at which period they separate, except when congregated round several vigorous plants. In October and November, according as the weather is more or less cold, the grub of the cockchafer buries itself in a gallery, the depth of which varies from 1 ft. 6 in. to 3 ft., and establishes his winter quarters under the roots of the trees or plants which he intends to feed on during the cold weather. In the month of September we counted sixty cockchafer grubs in the hollow stem of a dead Cherry tree. When it returns to the earth for the winter it measures $\frac{1}{2}$ in. in length, and 2-10ths of an in. in diameter. Every winter the cockchafer grub casts its skin. When the spring arrives the grub, guided by the increased temperature, comes to the surface, and prepares for ravaging the plants in the neighbourhood on a large scale. During this stage of its existence its growth is very rapid. When eleven months old it is $\frac{1}{2}$ in. in length, and 1-5th of an inch in diameter; a month afterwards it has increased to $\frac{1}{2}$ in. long and $\frac{1}{4}$ in. in diameter. The maximum development is reached in eighteen months, when it measures 2 in. in length and $\frac{1}{2}$ in. in thickness, the body being now covered all over with short reddish-brown hairs. For three years it carries on its ravages, the winter's cold obliging it to bury itself in the earth until the time comes for it to be transformed into the perfect insect. The larva of the cockchafer, like those of other insects, possesses but few faculties, except that of devouring everything within its reach, and of being very tenacious of life. The cockchafer grub does not walk, in the true sense of the term; it advances like an earthworm, by the alternate expansion and contraction of the rings of its body. When it digs its gallery it doubles on itself, the hinder portion serving as a support, while the head is thrust forwards. The mandibles break up the earth and the feet push it on one side, the body revolving on its axis, so to speak, at the same time, pressing and smoothing the sides of the hole. A vigorous grub will in this way dig a hole $\frac{1}{2}$ ft. deep in about an hour. When the grub begins to look out for food, the galleries are either horizontal or only gently sloping, but when it buries itself in the earth in order to take up its winter quarters or to undergo the change from grub to beetle, it digs a well or gallery that is nearly vertical; sometimes, however, it is formed of several broken lines, at others in gentle curves. It is at the bottom of these vertical holes that the shells or capsules in which the metamorphosis takes place are found. This change takes place in the course of the winter, the larva changing into the perfect insect by casting off its outer skin, which it leaves behind it at the bottom of the capsule. We may at times meet with cockchafers under the soil in January and February in a very advanced stage of transformation. The cockchafer grub is not dainty in the choice of its food; it feeds on all kinds of food alike, although there are some which it prefers to others, such as those of the Strawberry plant and Rose tree, but they may be also met with amongst the roots of the Dandelion, Leek, Parsley, Sorrel, salads, Grass, Lucerne, and at the base of young Cedars. When these plants, therefore, are grown in the neighbourhood of Rose trees they should be frequently examined to see if they are infested with these pests. It is consequently, on account of its preference for certain plants, that Rose growers plant or sow Cos and other Lettuces in the neighbourhood of

their Rose trees, in order to attract the cockchafer grub to the surface of the soil. Its presence may easily be detected by the withered appearance of the Lettuces. As far as insect-destroying manures go, I have, after many experiments, extending over several years, become convinced of their inefficacy, or rather of their utter uselessness. The larva of the cockchafer is possessed of a remarkable amount of vitality. Immersed for a full fortnight in water, it still lives, and after having buried it in dry earth for a whole month, I have found it alive and well at the end of that time. I have even plunged it into a strong solution of sulphate of copper (blue copperas) without hurting it. It also resists the action of a solution of carbonate of soda, which is so destructive to other forms of animal life. Even with fish manure, mixed with carbonate of soda, it escaped all injury, after having been submitted to its action for more than a month. Nothing in the ordinary way, except excess of heat or cold, will destroy it. For instance, if the thermometer sinks to only a couple of degrees beyond the proper point, the animal dies just as it does if it is submitted to the action of sunlight for only a quarter of an hour. We must come back, therefore, to our first advice, which is to attack the larvæ during the first year while they are still young and gathered together in groups. The most certain way, however, of destroying them effectually is to pick them off the plants in the morning and the daytime when they are half asleep. They should be thrown into tubs of lime-water, either alone or mixed with one-tenth of common petroleum or paraffin oil. They soon become suffocated in this mixture, after which they are burnt or buried.

USEFUL INSECTS.—If certain insects are the decided enemies of the Rose grower, there are others which are his friends, and which should be cherished as such. Amongst these we may count the coccinellæ, or garden beetles, which are strongly carnivorous, the bronzeed Rose beetle, the large black carabus, which is a frequenter of Box borders and the bases of walls, the coccinella, or lady bird, the larvæ of which devour the Rose aphid at the rate of fifty per head every day; they are generally found on the leaves of the Lime tree; the ichneumon, which destroys the larvæ of the lepidoptera and the aphid, and lastly, the churchyard or burying beetle. A dead mole, which was thrown on the path of one of our Rose gardens, was attacked by a couple of these insects, and a reinforcement of three other burying beetles came to the assistance of their friends. The next day there was no longer any trace of the mole in the pathway, but, at 2 ft. from the spot where the body had lain, at the edge of a border, I noticed a small heap of earth; it was the mole. The burying beetles, finding the soil of the pathway rather too hard for their jaws, they had transported their prey to a softer locality, and had buried it there, and, after having stripped it of its skin, were making preparations for laying their eggs in the dead body, wherein would breed a progeny of young larvæ, with their natural food ready to hand. The ordinary frog and the hated toad are also among the Rose grower's most faithful allies, seeing that they make great havoc amongst worms and young slugs. Owls and bats, too, feed upon nocturnal insects, and the little birds, which make a garden pleasant with their sweet harmonies, pay for the slight amount of damage they do by doing their best to relieve us of all kinds of insects, whether useful or injurious.

THE SYRPHUS FLY.—The Syrphus Pinastri belongs to the Diptera, and deserves to be particularly mentioned amongst useful insects. Its larvæ feed upon the Rose aphid, and it is generally about the middle of April, as soon as the larvæ of the aphid first begin to make their appearance, that we may see this fly, which has some resemblance to a small gadfly, poisoning itself over the young twigs which are covered with aphides. The vibration of its wings is so excessively rapid, that the eye can scarcely perceive their motion; at other times it may be seen resting itself on a leaf, from which it disappears at the slightest sound. This fly measures 4-10ths of an inch in length and 2-10ths of an inch in diameter, and is provided with six feet, two of which are inserted in the neck and the remaining four in the base of the thorax; they are black at the upper part of the thighs, and yellow in the middle, each being composed of five joints. The head is very large, with a flat white space in the middle, upon which may be noticed two antennæ, in the form of clubs, of a brownish-black hue, with two little filaments attached. The thorax is black, as well as the back, which are marked with three white bands, which grow smaller as they extend towards the base of the abdomen. The belly is flat, and is marked with four white transverse bands and two longitudinal streaks placed on the sides. The wings are very transparent, and are of the same length as the body. The female, with instinctive foresight, lays her eggs on the Rose leaves which are most likely to afford a good crop of aphides. It lays about the beginning of April, and continues laying at intervals until the end of September. Each female lays from eighteen to twenty eggs in two or three days. The eggs are as white as snow, and are of an ovoid shape; they measure 1-25th of an inch in length, by 1-50th of an inch in diameter, and

are glued to the edge of the leaf by the female by means of a glutinous substance which exudes from her body. When the larvæ issues from the egg the skin is of a dead white marked with a number of brown striae at the lower part of the back. It is $\frac{1}{8}$ in length and 1-25th of an inch in diameter at its birth, and it is only as it grows older that the skin takes its proper colour. When the larvæ arrives at maturity it is of a bright green hue, a divisional line of yellow running along the middle of the back, which is marked with black dots on each side of the line. The head is elongated, in the form of a trumpet, allowing a kind of black dart to be seen under the transparent skin. This dart is divided in two and serves to dismember the larvæ of the aphid on which it feeds. Seven pairs of processes indicate where the feet ought to be. It moves about with great difficulty, fixing itself by its head, curving its body and dragging it held firm as before. The larvæ has also the power of standing up, so to speak, on its hinder part, stretching out its body in search of aphides, which it pierces with its dart, holding it up in the air, and, sucking the juices out of its body, it throws away the empty skin and moves off in search of other prey. Its gluttony is so great, that we have seen it suck the interior out of six aphides in less than seven minutes. A single aphid we have seen devoured in eighty seconds; and when once it is gorged it fixes itself on the edge of a leaf to digest its meal, the rest of the aphides actually crawling over its body without being in any way molested. From the time it is hatched to the time it assumes the form of a perfect fly is generally about thirty days. When fully grown it is 3-5ths in. in length and about 1-10th in. in diameter. Before transformation it fixes itself by the head to the edges of a leaf by a silken thread; the body becomes shorter, and grows rounder towards the base; the skin turns of a bronzy hue; and the yellow band which divided the body in two disappears. The seven pairs of false legs are surrounded by the skin of the body, the whole forming a little cocoon, rounded at the base, and slightly pointed towards the summit, measuring $\frac{3}{8}$ in. in length by 1-12th in. in diameter. This cocoon sometimes turns to a bronze colour as the time for the ultimate change approaches; others, on the contrary, are smaller and preserve a dead white hue. It is possible that these smaller ones produce male flies, as they are fewer in number than the smaller ones. After twenty-four or thirty days the insect breaks the envelope of the cocoon, and takes flight in search of its male or female mate. Thus the larvæ of the last crop of eggs gives birth to those flies which pass the winter in the midst of decayed leaves and other shelters, seeking their fortunes as soon as the temperature will allow them to fly about, which is generally about the end of March or beginning of April. J. LACHAUME.

ANSWERS TO CORRESPONDENTS.

Autumn-flowering Herbaceous Plants.—Would you kindly give me the names of say three dozen of the best hardy herbaceous plants that would bloom in July and August, plants such as Delphiniums, to have a few of the best varieties named?—A.

Alstroemeria aurantiaca	Geum coccineum fl.-pl.	Pentstemon Hartwegii
Asclepias tuberosa	Hemerocallis fulva	Pentstemon gentianoides
Acrostichum Napellus	Lobelia cardinalis	Pentstemon Jaffrayanus
Achillea Patmifolia fl.-pl.	Lobelia fulgens	Pentstemon azureus
Betonica grandiflora	Linaria dalmatica	Pentstemon heterophyllus
Coreopsis lanceolata	Lilium auratum	Platycodon grandiflorus
Cassipouia speciosa	Lilium speciosum	Rudbeckia speciosa
Chelone Lyoni	Monarda didyma	Spiraea palmata
Chelone obliqua	Monarda fistulosa	Spiraea venusta
Delphinium Keteleeri	var.	var. pinnatifida
Delphinium Belladonna	Nepeta macrantha	Tritomoe Uvaria
Eryngium amethystinum	Oenothera fruticosa	Veronica virginica
Gentiana asclepiadea	Oenothera riparia	Veronica longifolia
Gentiana asclepiadea alba	Phlox decussata in variety	Zauschneria californica

Vicomtesse Hericart de Thury Strawberry.—Not being sure as to having the true variety of this, and wishing much to get up a good stock of the right kind for forcing, I should be glad if some of your correspondents will kindly state what are its distinguishing features. Those I have retain the petals till the fruit is far advanced, and to one's thinking would turn out indifferent settlers, as the anthers appear bare and pollen and are not pushed out well over the fruit.—S. [If the variety which you have does not set most freely and bear enormously, you certainly are not in possession of the true sort, as these are its special characteristics. Under ordinary culture the berries are of medium size, of flatish, conical form, and deep red; the flesh being also deeply tinged with red, very solid, and of a rich, brisk flavour. The foliage, which is very glossy, is light green, and so hardy that the late severe winter has damaged it but little. It is synonymous with Garibaldi, a most excellent Strawberry for any purpose.—W. W.]

Cattleya Flowers without Sheaths.—Two of my young plants of Cattleya Luyana have produced flowers without sheaths, the bud springing direct from the top of the bulb. Is not this very unusual? and how can I prevent it for the future? The plants seem healthy, and have produced flowers with sheaths at the same time. Those without sheaths were large and well coloured, but flabby, and fell down the day after expanding.—A. THORNTON Chorley. [Without seeing the plants alluded to, or having any idea as to the temperature and mode of culture to which the plants have been subjected, it is next to impossible to say why your plants have produced flowers without the usual sheaths, and especially as they have all at the same time borne flowers with sheaths in the

natural way. Too high a temperature with dense shading, may possibly have been one of the causes. The flowers fading or drooping so soon is a sign of weakness, want of moisture at the root or in the atmosphere, or of fertilisation having been effected. General weakness, but from what specific cause we cannot say, would lead to both the results named. Flowers produced without sheaths are most generally seen on the weakly secondary growths, which it is difficult to prevent some species of *Cattleya* from making.—B.]

Names of Plants.—*Mrs. G. R.*—1, a variety of *Narcissus* *Tazetta*, of the *Soleil d'Or* type, as cultivated in gardens; 2, *N. floribundus* of Jour. et Fourreau, the mossy *Hermione* (*H. floribunda*), of Haworth; 3, *N. poeticus* var. *Maialis*, the May-flowering *Poet's Narcissus*, of Haworth; 4, *N. G.*—1, *Ranunculus* *hederaceus*; 2, *Ranunculus auricomis*; 3, *Luzula campestris*; 4, *Anthoxanthum odoratum*.

NOTES OF THE WEEK.

Asparagus Planting.—It may not be amiss to note that the season will permit of this being done to a later date than usual this year. There are great quantities of foreign *Asparagus* in our markets now, but it is frequently most disagreeable in taste from the length of time during which the samples are on the way; hence another reason, if another were required, for making the home culture of *Asparagus* equal in all respects to that of any other country. Prizes for the encouragement of *Asparagus* culture, announced in this journal last year, and which are to be given for seven successive years, will commence two years hence at the great show of the Bath and West of England Society.

Primula mollis.—This, though an old introduction, is now rare in collections, a singular fact, considering that it is such a pretty species. We found it the other day in full bloom in the Royal Botanic Gardens, Regent's Park. It is quite distinct from any other cultivated kind with which we are acquainted; it appears to be intermediate between *P. cortusoides* and *P. sinensis*, but distinct from both. It grows about 8 in. high, with leaves somewhat triangular in outline, and covered on both sides with short dense hairs. The blossoms are nearly 1 in. across, of a lively rose-coloured tint, similar to that of the new *P. rosea*, but with the centre of a deeper hue. The colour of the calyx is singular, being of a rich red-purple on the lower part, and the segments green. The blossoms, which are arranged in whorls on erect stalks, open in succession from the base upwards. It is a native of the hills of Bhotan, at high elevations, whence it was introduced to our gardens about a quarter of a century ago.

Herbaceous Calceolarias.—There is just now a very fine display of these in one of the houses in Messrs. Suttons' grounds at Reading, so fine, indeed, both as regards perfection of growth and profusion and strain of flowers, that I have felt it to be my duty to draw attention to them, in order that those interested in these good old-fashioned flowers, who happen to be in the neighbourhood, may call and see for themselves. The plants average about 18 in. in width, and are so dwarf, yet vigorous, that anyone might fancy they had never been subjected to the slightest warmth; the flower-stems are of uniform height, and sufficiently strong to do without supports, these being used only to keep the flower-stems equi-distant. There may be seen amongst them all hues of colour, from creamy white to deep vermillion, and yellow flowers are the exception. This last is certainly a step in the right direction, as yellow flowers have long held the predominance.—W. W.

A New Pontederia.—A very beautiful and distinct species of *Pontederia*, at present unnamed, evidently new to cultivation, is now finely in flower in the Royal Botanic Gardens, Regent's Park. Its affinity is with the well-known *P. crassipes*, from which it differs in having long rhizomes, from which the leaves spring at regular intervals; also in having its leaf-stalks not swollen but of an uniform size throughout, and in having the leaf-blade wedge-shaped instead of heart-shaped. The blossoms are borne in much the same racemose manner as those of *P. crassipes*, and they are of the same mauve tint deepening towards the centre; they, however, differ from those of *P. crassipes* in having the yellow blotch on the upper petal much more distinctly defined, and most of all in having the margins of the petals beautifully fringed, which heightens their beauty considerably. It is a native of Brazil, whence it was brought and presented to the Royal Botanic Society in March last.—W. G.

Shrubs in Flower in Battersea Park.—Many beautiful shrubs now adorn the shrubberies and lawns in this park. *Berberis stenophylla* is in many spots a mass of golden blossoms, more particularly a fine specimen between the Antennaria-covered mounds, generally termed the "snowy mounds." It cannot be too highly commended for general planting, as it is much harder than *B. Darwini*, not being in the least affected by the past winter. It is a hybrid between *B. Darwini* and *B. empetrifolia*. *Ribes aureum* is another fine old shrub, the pendulous racemes of golden blossoms of which contrast finely with the pleasing green tint of the young foliage. It

makes a capital plant for associating with its better-known neighbour, *R. sanguineum*. The double crimson-flowering Peach (*Amygdalis persica* fl.-pl.) is one of the most brilliant objects we know of, especially when placed, as it is here, so as to have a good background of evergreen foliage. The double-flowering Cherry (*Cerasus vulgaris* fl.-pl.) is equally desirable, the pure white, rosette-like blossoms, which are borne in profusion, being extremely attractive. Another pretty shrub is the variegated-leaved *Kerria japonica*, which has apparently withstood the severity of the past winter unscathed. Its rich orange blossoms, mixed with the elegant white and green foliage, render it a very effective plant. The double-flowered *Spiraea* (*S. prunifolia* fl.-pl.) is a neat and pretty shrub; its small, white, button-like blossoms are produced so plentifully that the plants look like masses of snow. The handsome *Forsythias* (*F. suspensa* and *F. viridissima*) are now past their best, but only to be succeeded by a host of other fine shrubs equal to them in interest and beauty.—W. G.

The Lily of The Valley which Messrs. Hawkins & Bennett grow at Twickenham is now the admiration of Covent Garden. It is grown in the open ground, and brought into flower earlier by placing frames over it, instead of the usual way of raising the plants.

Dracænas at Anerley.—The fine collection of *Dracænas* in Mr. Wills' nursery is now well worth seeing. Here may be found superb specimens of the choicest hybrid varieties, comprising along with those that are now generally well known other beautiful kinds that have not yet been distributed. The different varieties are too numerous to individualise, but amongst those which most attracted attention were well-grown and highly-coloured specimens of *magestica*, *igneæ*, *Frederici*, *Gladstonei*, with flesh or magenta-tinted markings; the best of those with green and white variegation being *terminalis alba*, *Mrs. Wills, Regina*, all examples of high-class cultivation.

Hardy Flowers from Colchester.—We have received from the New Plant and Bulb Company, Colchester, cut flowers of a handsome *Muscari*, named *paradoxum*, but not that of *Baker*; *Iris iberica* (true), and a beautiful large-flowered variety of it, said to be very dwarf in habit; *Uvularia grandiflora*, a handsome North American *Lilium* plant; *Fritillaria recurva*, a pretty orange-blossomed species; *Trillium grandiflorum*; *Dodecatheon elegans*, a finely coloured American *Cowslip*; and the following *Orchids*, viz. *Cypripedium pubescens*, *Gymnadenia albidula*, and *Ophrys fusca*. The *Iris iberica* and its varieties grow, it is stated, unusually well about Colchester, and bloom most abundantly.

Hedysarum humile.—This is one of the most brilliant little gems on the newly-constructed rockery at Kew. It is a compact-growing perennial, not more than 3 in. high, having pinnate leaves with from seven to nine pairs of leaflets. The flowers, which are borne on short stalks, are arranged in dense clusters, and are of an intensely deep magenta hue, and therefore very showy. It should find a place on every rockery. It is apparently rare in English gardens, but the *Kew* plants being of Continental origin, it will doubtless soon become better known.

Posoqueria longiflora.—This very handsome, stove plant is now very attractive at Kew. It is an erect growing shrub with large leathery leaves of noble aspect. The blossoms are borne in large terminal clusters, and are nearly 6 in. long, with a greenish narrow tube; the petals, which are pure wax white, are arranged in a star-shaped manner, and exhale an agreeable aromatic perfume. It is a member of the *Cinchona* family, to which so much attention has recently been directed, and a native of Guiana.

Pelargonium Society.—It being desirable that all the novelties exhibited for the Society's Certificate of Merit should be presented in the best condition for adjudication, we understand that arrangements will be made so that the censors and executive committee will meet for that purpose on June 24, as well as on July 8, the latter day having been adopted for the Society's show instead of the former, in consequence of the lateness of the season. In submitting the new varieties for adjudication, Rule 7 must be strictly observed. On June 24 any plants that may be staged will be placed in the conservatory. As the Royal Horticultural Society has fixed July 9 for its evening *fête*, the leaving of the exhibits over the night of the 8th must be entirely at the option of the exhibitors.

Alteration of Date of Rose Show.—Putting back the date of the National Rose Show I regard as a wise step, as the queen of flowers, like everything else, is quite a fortnight later this season than usual. Some excellent vegetable prizes are offered at this show by Messrs. Carter and others, and it is to be hoped the awarding of them may also be put off until the 8th of July; as I fear few Peas, Potatoes, Cauliflowers, &c., will be in show condition by June 24 this year.—CAMERIAN.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

MAY 21.

The first summer exhibition of this society was held last Wednesday, and, notwithstanding that some of the classes were but scantily represented, the tent was well filled. The absence of Pelargoniums and pot Roses, except in one class, was conspicuous, as on previous occasions they formed such an attractive feature. The Roses from the Waltham Cross and Cheshunt Nurseries (not shown for competition) were, however, particularly noteworthy, and added greatly to the attractiveness of the exhibition. Messrs. E. G. Henderson and Sons, St. John's Wood, exhibited a very effective bank of well arranged plants, consisting of Palms, Orchids, Ferns, &c. Besides the novelties certificated were noticeable *Coburgia luteo-viridis*, the beautiful *Bertolonia Mirande*, *Amaryllis Harleyana*, and many others; also a fine batch of *Naectochili* in good condition. Messrs. Veitch and Sons furnished a small, but excellent group of new and rare plants, many of which obtained certificates. *Ranunculus Lyalli* was again shown in flower, but not so fine as hitherto. Some flowering specimens of the new hybrid *Cypripediums* were shown, viz., *C. calanthum*, and *C. superciliale*, both distinct kinds. From Mr. Bull came a numerous collection of new and rare plants, several of which were certificated; also a tastefully arranged group of Orchids, Ferns, Palms, and other plants. Mr. B. S. Williams sent a large and rich collection, containing many plants of interest, which were much admired, and several of the new kinds received certificates of merit. From Messrs. John Laing & Co., Forest Hill, came a small but tastefully-arranged group of fine-foliaged plants intermixed with *Azaleas*, *Gloxinias*, and *Begonias*, of which some were certificated. Similar groups also came from Messrs. Hooper & Co., Messrs. Osborn & Son, and Mr. G. Wheeler. Mr. H. Boller, Kensal New Town, exhibited a small collection of Cacti, including large specimens and many in miniature pots. A magnificent display of *Clematis* came from Messrs. Jackman & Son, Woking Nursery. These were shown in pots gracefully trained on balloon-shaped trellises, and were splendid examples of high-class culture, all being very finely bloomed. Those with the light-coloured flowers were *Fair Rosamond*, Mrs. S. C. Baker, Maiden's Bush, Miss Bateman, and Vesta. The best of the dark purple kinds in various shades were *Sir Garnet Wolseley*, *Lord Lonsborough*, *Lord Mayo*, *Albert Victor*, *Lord Derby*, *Aureliana*; all the above being varieties of sterling merit and highly desirable. An effective group of Pelargoniums, intermixed with the fine new *Victoria Lily* of the Valley, was sent by Messrs. Hawkins and Bennett, Twickenham, and were much admired. Mr. George, Putney Heath, exhibited cut blooms of new varieties of *Abutilons*, which were very fine. From Messrs. E. G. Henderson & Sons came cut blooms of a very fine strain of *Mimulus* in excellent condition.

Botanical Certificates were awarded to—

Cypripedium, species from Java (Veitch).—A very distinct novelty, with flowers as large as those of *C. villosum*, the upper sepal being green with creamy-white margins, the lateral sepals being rich brown and spotted at the edges, and the lip of a paler hue, the whole flower having a very glossy appearance.

Cypripedium Boxalli (Bull).—A species in the way of *C. villosum*, but very distinct.

Sarracenia atro-sanguinea (Bull).—A handsome new variety, similar to *S. rubra* in habit and form of pitchers, but, in addition to the red network of veins, with the upper half of the lid of the pitcher of a deep blood-red colour.

Tillandsia zebrina major (Veitch).—A variety with an unusually large spike of scarlet bracts and yellow blossoms.

Phædranassa chloracea vera (Henderson).—A beautiful bulbous plant, with long, tubular flowers of a deep flesh colour, tipped with dark green, the blossoms hanging gracefully in umbels from stout, glaucous stems about 2 ft. high.

Tulipa stellata (Bull).—A beautiful early-flowering Himalaya Tulip, allied to the old *T. Clusiana*, but with the blossoms whiter.

Spiræa nivosa (Bull).—A very pretty and graceful novelty, similar in appearance to *Astilbe japonica*, but with broader foliage, denser flower-heads of snowy whiteness.

Nephrolepis pluma (Veitch).—An elegant kind with long pinnae and gracefully arching fronds.

Asplenium horridum (Williams).—A distinct Fern with broad fronds, the stripes of which are covered with a fulvous, downy substance.

Polypodium Kremeri (Veitch).—A very elegant novelty, of dwarf growth, reminding one of *P. Dryopteris*.

Todea plumosa (Veitch).—A charming new Filmy Fern in the way of *T. superba*, but more transparent, of a pale green.

Pteris cretica hybrida gigantea (Henderson).—A very robust and highly ornamental variety of this favourite Fern, growing over 3 ft. high.

Doodia aspera var. *multifida* (Veitch).—A pretty variety, with the tips of the fronds divided into numerous segments.

Cupania elegantissima (Williams).—A decorative plant of graceful habit, with pinnate leaves resembling some of the Cycads.

Croton Burtoni (Williams).—An elegant variety, with long drooping leaves, having undulated margins, and prettily mottled with yellow and green.

Croton Evansianum (Bull).—A variety with an erect habit, the leaves of which have a tendency to be trilobed, and all of them are more or less richly coloured.

Croton Dormanianum (Bull).—A distinct form with ovate leaves, also finely variegated.

Asparagus gracillimus (Bull).—A graceful climber, with slender stems, and small rich green foliage.

Zamia obliqua (Bull).—A handsome Cycad, with bold leaves and broad glossy oblique leaflets.

Cypophentia macrocarpa (Bull).—A noble-looking Palm, with bold pinnate leaves, which, when young, assume a rich purplish-red tint.

Cycas siamensis (Bull).—A novelty in the way of *C. circinalis*.

Cycas pluma (Bull).—Also an elegant plant, with arching foliage.

Catekidozamia Miqueliana (Bull).—A species of graceful, yet bold habit.

Dracæna Laingi (Veitch).—A very ornamental and distinct variety, with prettily variegated foliage, which droops gracefully.

Erythrina marmorata (Veitch).—A very desirable novelty, having its leaves beautifully mottled with various shades of green and white.

Cattleya Skinneri alba (Bull).—A charming white-flowered variety of this fine Orchid.

Ranunculus Lyalli (Veitch).—A handsome New Zealand plant, described and figured in our columns last week.

Oncidium tetracopis (Bull).—A handsome novelty in the way of *O. crispum*.

Encephalartos Hildebrandi (Bull).—A decorative Cycad, of graceful habit.

Floricultural Certificates were awarded to—

Rhododendron Duchess of Teck (Veitch).—A beautiful variety of the tubular-flowered greenhouse section, bearing large clusters of blossom, of a delicate orange tint, suffused with pink.

Begonia Comtesse H. de Choiseul (Laing).—A desirable novelty, with perfectly double flowers of good form, and of a delicate bluish tint.

Begonia Marie Bouchet (Laing).—Another double-flowered variety, with beautiful rosette-like blossoms, of a rich crimson colour.

Begonia J. H. Laing (Laing).—A brilliant scarlet-coloured variety, with single flowers, of a large and very fine form.

Begonia Jaubrey Clark (Laing).—Also a desirable acquisition, with bright scarlet blossoms and handsome foliage.

Begonia Zulu (Hooper).—A beautiful variety, of robust habit, having elegant foliage and brilliant scarlet flowers.

Caladium L'Albane (Osborn).—A novelty with very beautiful foliage, the ground colour being transparent white suffused with pink, and distinctly veined with green.

Azalea mollis Comte de Gomer (Veitch).—A beautiful variety, with large, deep, rose-pink blossoms.

A. mollis Baron Constant Rebecque (Veitch).—Similar to the foregoing, but with flowers of a rich yellow colour.

A. pontica Graf Von Moran (Veitch).—A very pretty and free-flowering variety, much resembling the singular form *A. narcissiflora*, but with the flowers of a deep bluish tint.

Gloxinia Duke of Connaught (Veitch).—A beautiful variety of the erect flowered type, with large white-edged blossoms of a rich purplish-crimson colour.

“Coleus Empress of Germany” (Bull).—A superb variety, with the leaves of a bright reddish tint, having a slight edging of gold.

Coleus Starlight (Bull).—Another very beautiful form, having wavy-edged leaves of a deep rosy hue, margined in yellow.

Coleus Harlequin (Bull).—A handsome variety, with the foliage very gorgeously marked with various tints, quite distinct from any which we have seen.

Coleus Butterfly (Bull).—Also a very desirable kind, having leaves deeply toothed, of a violet-rose tint, edged with pale yellow.

Pansy Champion (Hooper).—A pretty variety, of good form.

Mr. Boller, of Kensal Town, received certificates for *Mammillaria filifera*, *M. formosa*, and *Echinocactus myriostigma*, all interesting Cactaceous plants.

Miscellaneous Plants.—The class for twelve stove and greenhouse plants (nurserymen) was but poorly represented, there being but one entry, and that from Messrs. Jackson & Son, Kingston, who showed a good collection, the best plants in which were *Imanophyllum minimum*, with over a dozen large heads of flowers; *Hedera tulipifera*, *Rhododendron Countess* of Haddington, large and finely flowered; *Erica depressa*, *Boronia pinnata*, *Aphelexis macrantha rosea*, and others, all fine examples. In groups of ten plants (amateurs), Mr. Chapman, gardener to F. Spode, Esq., Rugely, was first. He had *Erica Cavendishi* 4 ft. through and well flowered; *Dracophyllum gracile*, a superb example, as was also *Statice profusa*. *Ixora coccinea* was staged in splendid condition; also *I. Prince of Orange*. *Azalea Mars*, *Chorozema Chandleri*, *Hedera tulipifera*, and the sweet-scented *Erica odora rosea* were all fine examples of high-class culture. The second prize went to Mr. G. Wheeler, gardener to Lady Louisa Goldsmid, Regent's Park, whose specimens, though somewhat small, comprised some well-bloomed examples, the best being a large plant of *Erica affinis* and a fair-sized specimen of the pretty *Aotus gracillima*. The class for six stove and greenhouse plants brought out three entries, the first prize being awarded to Mr. Chapman, who had a remarkably even group containing splendid examples of *Erica depressa*, *Tremandra ericifolia*, *Dracophyllum gracile*, *Acrophyllum venosum*, *Ixora Prince of Orange*, and *Anthurium Scherzerianum*. The second prize went to Mr. J. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, whose best plants were *Azalea Iveryana*, *Aphelexis macrantha purpurea*, *Hedera tulipifera*, and *Erica depressa*. Mr. G. Wheeler was awarded the third prize for a small but well-flowered group. In the nurserymen's class for six, Messrs. Jackson & Son were the only exhibitors, with finely-grown plants of *Hedera fuchsoides*, *Boronia serrulata*, *Aphelexis macrantha purpurea*, and others.

Orchids.—These formed a prominent and very beautiful feature, and though the entries were not numerous, some capital groups were shown. In the amateurs' class for twelve plants, Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, staged a splendid lot for the first prize, the most noticeable being a grand plant of *Dendrobium nobile*, over 3 ft. high and as much through; *Cattleya Warneri*, a magnificent variety; *Cypripedium villosum*, with two dozen flowers; *Masdevallia Harryana*, a deep-coloured variety with eighteen blossoms; *Odontoglossum Roezeli* and variety *albidum*, *O. vexillarium*, and *O. Phalaenopsis*, all superb plants. An admirable collection was also shown by Mr. Heims, gardener to F. Philbrick, Esq., Avenue Road, Regent's Park. The best of these were a grand plant of *Cattleya Skinneri*, very rich-coloured form, *Lelia purpurata*, *Cattleya Mendelli*, *Dendrobium thrysiflorum*, *Maxillaria Turneri*, and others, all in fine condition. In the nurserymen's class for twelve Orchids Mr. B. S. Williams was awarded the first prize for a group consisting of the lovely *Dendrobium Parishii*, a fine plant; *Vanda swartzii*, with four large racemes; *Lelia purpurata*; the gorgeous *Cattleya Mendelli*; *Masdevallia ignea*, a pale-flowered form, but finely bloomed; the novel *Cypripedium Swianium*; *Masdevallia Lindeni*, with over two dozen highly-coloured blossoms, and others. Mr. Henry James, Castle Nursery, Lower Norwood, also competed, and was deservedly awarded the second prize, his plants showing superior cultivation and rich variety. The most noteworthy were *Dendrobium Wardianum*, a fine example of this lovely Orchid; *D. nobile*, a grand plant; *Oncidium oncolor*, *O. crispum grandiflorum*, *O. Marshallianum*, and *O. sarcodes* were also well flowered; also *Dendrobium thrysiflorum* and *Cattleya Mendelli*. Messrs. Jackson & Son were awarded third prize in the same class.

Roses.—The classes for Roses in pots were but scantily filled, a fact doubtless owing to the backwardness of the seasons, though the Messrs. Turner, of Slough, made a very effective display in the class for twenty plants in 8-in. pots. Amongst these the best flowered were—*Perfection de Montplaisir*, a Tea-scented variety, of a fine canary-yellow; *Duchesse de Valombrosa*, flesh colour, shaded with

rose; *Souvenir d'un Ami*, Jean Liabaud, *Mademoiselle Thérèse Levet*, *Captain Christy*, *Royal Standard*, *Princess Beatrix*; all also very fine. The Cheshunt and Waltham Cross Nurseries contributed superb collections of cut blooms, not for competition. These were deservedly much admired, as they included some exquisite examples. Amongst those from Messrs. Paul & Son were splendid trays of Tea-scented varieties, such as *Maréchal Niel*, *Céline Forestier*, the lovely Cheshunt Hybrid, *Belle Lyonaise*, and others. From the Waltham Cross Nurseries came a very fine group, including the finest of the Hybrid Perpetuals, Tea-scented, and other kinds in capital condition; also a well-filled tray of a Banksian Rose, named *Rosa Banksia odoratissima*, a very sweet-scented variety, with pale sulphur-yellow double small blossoms in large clusters.

Azaleas.—These, as is usual in May, formed a very prominent feature of the show, and the classes into which they were divided were numerous and well filled. For six for competition amongst amateurs the first prize came from Mr. A. Ratty, gardener to R. Thornton, Esq., The Hoe, Sydenham, who staged a first-rate group; indeed, as fine as we have yet seen. It comprised *Georgiana*, a gigantic pyramid of blossoms of a deep orange-scarlet; *Criterion*, *Exquisite*, *Distinction*, in various shades of pink; *Model* and *Eulalie Van Geert*, all admirably grown and effectively staged. Mr. G. Wheeler exhibited a collection of smaller-sized plants for the second prize, several of which were remarkably well bloomed, and judiciously selected as regards variety. An extra prize was awarded to Mr. J. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, for six plants of small size. In the nurserymen's class for six, Mr. Turner and Mr. Williams competed, and took first and second prizes respectively. The former group consisted of fair-sized and well-bloomed plants, some with very large flowers, such as *Duc de Nassau*, *Duchesse de Nassau*, and *Reine des Fleurs*. For twelve plants in 12-in. pots, Mr. Ratty was again first with capital examples, his best being *Stella*, *Juliana*, and *Model*; the other competitor was Mr. Turner, who had a very even group. In the class for six in 12-in. pots for amateurs, Messrs. Ratty, Child, and Wheeler were the competitors.

Heaths were but second-rate, and the entries few. Messrs. Jackson secured the first prize for twelve in the nurserymen's class; the second prize went to Messrs. Peed & Son, Norbury Vineyard Nurseries, Lower Streatham. The class for six only brought out one exhibitor, Mr. G. Wheeler, to whom the second prize was awarded for a somewhat uneven collection.

Ferns.—In the amateurs' class for six exotic ferns, Mr. Douglas took the first prize with a good group, the most noticeable plants in which were *Adiantum concinnum latum*, *Gleichenia Splenacea*, and *Davallia polyantha*. Mr. Wheeler took the second with an evenly-grown group, comprising *Adiantum tenerum* and *Alsophila excelsa*. The nurserymen's class was represented by only one collection, which came from Mr. Williams, and consisted of a grand mass of *Adiantum Farleyense*, *Davallia Mooreana*, *Gleichenia Splenacea*, and *G. rupestris*.

Fine-foliaged Plants.—These were shown in splendid condition. Amongst the amateurs, Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Sussex, staged a grand collection for the first prize, consisting of superb examples of *Croton interruptum*, *C. variegatum*, *Zamia Lehmanni*, *Cycas revoluta*, *Areca sapida*, and *Latania borbonica*. The second prize went to Mr. Ford, gardener to J. G. Meegan, Esq., Windermere House, Norwood, whose plants included some magnificent specimens, especially a gigantic *Diefenbachia picta* of a size rarely seen; also *Alocasia metallica* in first-rate condition. For the third prize Mr. Douglas staged an evenly-matched half-dozen, including *Cocos Weddelliana*, *Croton Wismannii*, *C. undulatum*, in good plants. An extra prize was also awarded to Mr. R. Butler, gardener to H. Gibbs, Esq., Regent's Park, for a small but effective group. In the nurserymen's class Mr. Williams secured the first prize with a fine group, amongst which *Dasylirion acrostichum*; *Pandanus Veitchii*, *Phormium tenax variegatum*, were noteworthy. The second prize came from Messrs. Hooper & Co., who showed fair-sized specimens in choice variety.

Hardy Flowers.—The class for Alpines in pots was badly represented, the only exhibitor being Mr. Parker, Tooting Nurseries. Amongst these were *Saxifraga muscoides purpurea*, a little gem but 1 in. or so high; *S. Mawana* was also shown in fine flowering condition. Some well-filled baskets of the brilliant *Gentiana acaulis* formed a very beautiful feature in Messrs. Osborn & Son's collection, as was also the beautiful little *G. verna* in that of Messrs. Henderson & Son. Cut blooms of the curious yet handsome *Iris iberica* were very noticeable in Messrs. Veitch & Son's group, and were much admired. A numerous and choice collection of cut blooms of *Pansies* was exhibited by Mr. H. Hooper, of Bath, the newer varieties amongst which were very beautiful. A flowering branch of *Pyrus (Malus) floribunda* (figured in THE GARDEN, Vol. X., p. 384) was sent by Mr. A. Waterer, Knap Hill.

A list of awards will be found in our advertising columns.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

ALPINE FLOWERS AT YORK.

In speaking of the Alpines now in flower on the rockwork in Messrs. Backhouse's nursery at York, I will mention them just as they occur to me. The rock garden is approached from the north by means of a zig-zag path sunk towards the lower end considerably below the ordinary ground level until the banks become so steeply that rocks are required to hold them up. Here the rockwork proper commences. The first plants which attract attention are huge masses of *Primula Auricula marginata*, bearing large trusses of yellow fragrant blossoms, and associated with these may be seen two fine specimens of a rare Saxifrage (*S. Tombeana*), a species which produces white flowers early in the spring. Here, on looking round, one sees every ledge and fissure occupied by Alpine plants, amongst which some of the finest are *Myosotis rupicola*, *Erysimum pumilum*, *Saxifraga lantescens*, *Anemone fulgens*, *Phlox subulata*, *Sedum asiaticum*, *Aubrieta græca superba*, *Alyssum saxatile compactum* and *A. montanum*. This last is a very useful plant for a hot, dry position, where it flowers most profusely. It is a very dwarf kind, and bears large heads of showy yellow flowers, though the whole plant is not more than from 3 in. to 4 in. high. A few paces further on and a narrow neck of water is reached, a sort of connecting link between two pieces of water. To the right are examples of the mountain Pine (*Pinus montana*) with crooked and weather-beaten stems, which, overhanging the track, give the whole place an air of Alpine rusticity. A little further on still is a shelving bank of stony earth interspersed with Alpine plants, and a bank of Grass in a sort of semi-wild condition. To the left, that is, on the opposite side of the water, in the distance are large Pines, Spruces, Larches, &c., while in close proximity, and shelving down to the water's edge, may be seen a combination of *Polystichum*, *Lastreas*, *Polypodium*, *Cystopteris*, *Adiantum pedatum*, *Struthiopteris*, *Orchides*, *Globe-flowers*, *Lily of the Valley*, and wild *Primroses*, all struggling for existence amongst the Grass. Advancing a few strides and pushing past another veteran bush of the Mountain Pine, a pond of water is reached, and looking across to an island just opposite may be seen large tufts of the English Lady's Slipper (*Cypripedium Calceolus*), and very fine indeed they must be when in flower. I also noticed two fine patches of the new rose-coloured *Primrose* (*P. rosea*) in a remarkably thriving condition planted near the water line. The same remark also applies to *Saxifraga pedemontana*, a kind, I believe, seldom seen in gardens. It is a distinct plant, having large, thick, deep green leaves, and bearing panicles of large, showy, white flowers. A lovely display of *Myosotis dissitiflora* and *Narcissus juncifolius* intermixed next presented itself on a steep bank faced with stone, the earth sloping down to the walk, and the yellow flowers of the Daffodil mingling interestingly with the blue blossoms of the Forget-me-not. Hanging from the rocks is *Cytisus Arduini*, a fine dwarf Alpine shrub, bearing arching racemes of golden-yellow blossoms; and at the foot of the rocks in a damp and shady nook, *Andromeda fastigiata* forms quite an attractive feature. It is by no means a common plant; in fact, it is rarely seen in such good condition as it is here, where it forms a tuft 18 in. across, loaded with *Lily of the Valley*-like flowers of exquisite loveliness; associated with it is another pretty dwarf evergreen shrub, viz., *Menziesia empetriformis*. On the ledges up among the rocks grows the white *Fritillaria*, a desirable plant anywhere, but, situated where its pure white bell-shaped flowers can be seen from below, its beauty is greatly enhanced. Pushing forth from the base of a huge rock is *Meconopsis aculeata*, a plant which grows from 2 ft. to 3 ft. high, and bears nearly throughout its entire length a profusion of large saucer-shaped, nodding, purplish-blue flowers. Unlike *Meconopsis nepalensis*, this plant is a true perennial, and is on that account of much more value than that kind. Now we have reached the south and main portion of the rockwork on which flowers are very numerous and beautiful. One of the most prominent features here is a large conical summit clothed with *Gentiana acaulis*, completely smothered with flowers, and a solitary tuft of the white *Fritillaria* and a mass of *Arabis albidia* greatly enhance the beauty of the blue flowers of the *Gentian*. A more beautiful sight than this it would, I think, be difficult to find. Near this spot are two fine kinds of dwarf *Iris*; one, *I. obliensis*, from 2 in. to 4 in. high, and bearing large, deep blue flowers; the other, *I. Cengialis*, a little taller, and with even larger and deeper and more intense blue blossoms. To the Alpine Poppy, with its yellow, white, and scarlet flowers, belongs quite a charm of its own;

and *Lithospermum tinctorium*, a new species, is a real gem; it has large, very dark, brilliant, blue flowers, which continue in perfection for many weeks, and it is a plant by no means difficult to grow. The Arctic Bramble (*Rubus arcticus*) is a desirable plant; it has rose-coloured flowers, borne on slender stems from 2 in. to 4 in. high. Associated with this was a beautiful Violet with pure white, wax-like flowers—a white variety of *V. pedata*. *Delphinium tricolor*, a dwarf Alpine Larkspur, is another valuable acquisition. Its flowers, which are purplish-blue, possess an indescribable lustre, and are borne in a compact spike from 4 in. to 6 in. long, the whole stem being from 6 in. to 12 in. high. *Veronica stauræifolia*, a prostrate kind with pale blue flowers; *Ranunculus Bertolonii* and other rare *Crowfoots*; *Silene acaulis*, *grandiflora*, and *alba*; *Erysimum rheticum*, &c., may all be seen here to advantage.

Near the base of the rock the ground has been formed into irregular mounds, and into the lower parts have been introduced vast quantities of bog-earth in which the following plants seem to be in a thriving condition, and some of them are in flower, viz., *Trillium grandiflorum* and the dark-flowered *T. erectum*, *Erythronium giganteum*, *Primula cortusoides amena*, a tuft fully 1 yard in diameter, full of flower; *Iris cristata*, a little beauty in boggy places; *Mertensia paniculata*, a charming kind; various kinds of *Globe-flowers*; and different species of *Pyrola*. Here, too, on raised portions of the ground I noticed *Polygala Chamebuxus purpurea*, which is, without doubt, the most beautiful Alpine that has been introduced for a long time. It is very dwarf and neat in habit, evergreen, and produces its flowers, which are deep purple or magenta with an orange centre, in great profusion. I must not omit to mention the *Lady's-slippers*, which, though not in flower, bid fair to be very gay. *Cypripedium spectabile* and *C. pubescens* are unusually vigorous.

Leaving the rock garden and passing through an opening in the trees, we find ourselves amongst Alpine plants cultivated in pots, plunged in 4-ft. beds, and in one of these beds there is just now such a display of the Vernal *Gentian* as I never remember witnessing before, at least in cultivation. There must be some hundreds of flowers, the whole forming a compact mass of the most dazzling blue.

P.

RAISING ANTIRRHINUMS FROM SEED.

THE homely Snappedragon, with its old-fashioned associations and its bright, cheerful, delicate, and pleasing colours, is one of the most attractive of our hardy biennials, and is perhaps as prodigal of bloom as any other plant that can be named. But such a severe winter as that which we have just passed through, following upon a wet autumn, has sorely tried the plants, and whole plantations of them growing in retentive ground have been killed outright. Where plants have occupied lighter ground, or a drier position, many of the Snappedragons have escaped; but many more in less favoured spots are utterly lost. It has been an exceptional winter, and many years may elapse before another happens so trying in its effects on vegetation generally.

It is usually recommended that the seed of *Antirrhinum* be sown in July to have plants to winter for the following summer. A better plan than this can be adopted, carrying with it greater advantages, namely, to sow seeds in January or February in a gentle bottom heat, and by pricking off the young plants into pans and boxes, get them on into size as speedily as possible. If these be planted out in a prepared bed at the end of May or early in June (taking advantage of showery weather to do so), they make good bushy plants by August, and all bloom at the end of that month and through September. The advantage of this plan is that the cultivator sees the quality of his flowers the same season as they are raised from seed; he can reject inferior ones, and utilise the best varieties for planting in prominent positions in autumn and spring. If the winter cuts his plants off, he will have seen something of their value; and any thing particularly good can be lifted and put into a cold frame, or some other place of protection to keep them from the possibility of harm.

Exhibitors of *Antirrhinums* at exhibitions held in July and early in August will find the foregoing method a good one for obtaining some good spikes of bloom for show purposes at the end of June and early in July, if they be required so early in the summer. Cut blooms of *Antirrhinums*, shown in bunches of three, four, or six spikes, find a place in many schedules of prizes, and when cut from good varieties and well arranged in a cut flower stand they are very attractive. The plants that flowered the previous September, if they survive the winter, which they do in nine cases out of ten, grow into good size by July, and furnish very fine spikes of bloom.

In proportion as the *Antirrhinum* receives generous treatment, so will it produce fine blossoms. What might be termed a holding loam, well manured, and deeply dug before planting, makes an excellent bed; and in order that the plants may display themselves to the

best advantage they should be planted at least 18 in. to 2 ft. apart each way; this gives them ample space in which to develop. The seedling plants might be planted out nearer together in May and June, and the very best sorts replanted in another bed in October, lifting the plants with good balls, and treading the soil firmly about them. If a severe winter follows, these transplanted plants are likely to suffer more severely than those not disturbed.

During the past ten or twelve years the habit of growth of the Antirrhinum has become much dwarfer than it used to be. I can remember thirty years ago when Mr. J. Riley, at that time of Huddersfield, used to get Antirrhinums to great dimensions, and it is on record that one of his plants, flowered in 1848 with others produced from cuttings of the best seedlings raised in 1847, measured 7 ft. high and 4 ft. 2 in. in diameter; and this specimen, though the largest, was not very much above the average of the plants obtained, be it remembered, from cuttings taken the previous autumn. In the case of small gardens, plants of that size would be very embarrassing, but from such plants it was not unusual to cut spikes 24 in. in length.

A good type of Antirrhinum is one that is of dwarf, compact, and yet free branching growth, and from 2½ ft. to 3½ ft. high when in full bloom. The Tom Thumb varieties are much dwarfer; the Continental types are often of inferior quality, but some of them are very pretty. They are being improved upon, especially in the way of obtaining very handsome striped flowers.

The Snapdragon deserves a hearty welcome to every garden. Those who have not sown seeds of it should do so at once, in order to secure good plants for flowering early next summer. R. D.

HARDENING OFF SUMMER BEDDING PLANTS.

THOSE who have much bedding out, as it is called, to do know full well that the plants which they employ should be, when placed in the open air, both healthy and vigorous. Our summers are subject to considerable fluctuations of temperature, and the season throughout is often so unfavourable that weakly or unhealthy plants have but little chance of succeeding. Anything, therefore, which tends to check them when turned out of their winter or spring quarters should be carefully avoided. And yet one often sees the ordinary run of bedding plants subjected to treatment that cannot but prove inimical to their future welfare. A common practice is that of placing them, when removed from glass structures, under wide-spreading trees. It is true that they are there protected from frost, but in other respects such positions, unless exceptionally well-sheltered, are unsuitable. The chilly wintry air which too often prevails in May blows through them, and so cripples them, that they need half the summer to regain their normal vigour. Where there are plenty of cold frames hardening off is an easy and satisfactory process, as on cold nights and windy, chilly days the sashes may be left on, merely allowing free ventilation. Hardening off may then be so gradually conducted, that the plants will retain all their freshness and vigour, and will go into their summer quarters with an unimpaired constitution. Plants thus treated will be certain to outstrip those which may have become crippled from hasty exposure. These remarks apply even to such comparatively hardy subjects as zonal Pelargoniums, Lobelias, &c., but they are still more applicable to such tender plants as Coleus, Cannas, &c., which are at all times impatient of cold draughts and sudden chills. Spring-struck Verbenas, Alternantheras, &c., often show the effects of reckless exposure the whole summer through, and many of the failures in Verbena culture might be traced to this cause alone.

The process of hardening and solidifying the tissues of young plants must be a very gradual one. In this matter the grower will have to be guided by the nature of the plant, and the way in which it has been treated during the winter and spring. Autumn-struck Verbenas and Calceolarias, for instance, may be hardened off and rendered capable of bearing full exposure, except on frosty nights, by the beginning of April; whereas many of the more tender kinds of bedding plants, and most of the so-called sub-tropical plants, can scarcely be fully exposed until the beginning and sometimes the middle of June. Tricolor Pelargoniums, for instance, in three seasons out of four, succeed best if kept in sheltered quarters until the second week in June.

Those with whom frame room is scarce during April and May should endeavour to provide some kind of efficient protection for their plants when turned out of the glass structures. A span-roofed framework constructed of stout 9-in. boards for the sides and ends, with a light, strong, ridge board and some bearers nailed thereto to support the mats, will be found capable of affording ample shelter, and if about 8 ft. in width, every plant therein will be well under the eye, and may be easily watered. These protectors should be erected in the warmest, sunniest corners in the garden, where, if possible,

the east winds which are apt to prevail in the spring do not touch them. Therein all may be covered up secure and warm on frosty nights and cold days.

A more simple, but equally efficacious, contrivance may be made with Hazel rods, bending one from each side, and tying them in the middle. In fact, spring protections are so easily and inexpensively constructed, that the wonder is that they are not more extensively used for all kinds of purposes. Not only do they afford the shelter which in cold seasons is so much needed, but they enable us to enjoy both fruit and vegetables at an earlier period than we can obtain them when they are fully exposed. Whether the garden be large or small, some system of protection should, therefore, be organised. One season's trial will convince the most sceptical that time and care bestowed on hardening off bedding and sub-tropical plants are not mispent, and that, even in the case of the commonest and hardest kinds, the treatment just indicated is better than merely placing them under the shelter of trees or walls. J. CORNHILL.

Byfleet.

AURICULAS—WHITE MOULD AND POTTING.

I AM not sure that botanists have determined this to be a Fungus, but I term it so for the sake of giving it a definite designation. It is sometimes called the white mould, and it fastens itself on the roots of the plants that wind themselves about the insides of the pots, and if the soil about the roots becomes dry, and the plants kept in a warm place, it appears to spread with remarkable rapidity until the whole of the roots exterior to the ball of soil are affected by it. The presence of the mould soon shows itself in the plants, the leaves turn sickly, and the plants get into a very poor state of health, and sometimes die. Years ago, it was known to the old growers of Auriculas as the "white froth," and they used to find it in the heart of the plants where it can be too often met with in these days, and they have left on record their experience, that if it is allowed to remain it will be pretty certain to induce canker.

How it originates, or what causes predispose it to appear on the roots have not been made clear to growers. But it exists, and it is a very troublesome pest. It showed itself on a very few of my plants, and the leaves soon told the tale. As soon as there were signs of the presence of the mould, the soil was shaken from the roots and burned; the roots were carefully washed in soft water, and well rinsed after, and the plants put into small pots to induce renewed root-action as soon as possible. Every grower who has the mould in his collection, will do well to utterly destroy all traces of it by burning the soil, and so stamping out any remains of it.

As a precautionary measure, I think growers will do well to be very careful as to the character of the leaf-mould they use for their Auriculas. I am under the impression that the "white froth" is a Fungus generated by vegetable matter in a certain stage of decomposition, and I have been led to take up this supposition from the fact that I used a certain lot of leaf-mould in potting a few of my plants, and these very plants included the worst affected. The leaf-mould should be so decomposed as to be literally mould and with no trace of any leaf in it. This should be turned over, sweetened, and well exposed before being used. Auricula compost should be as well sweetened and seasoned as it is possible for mould to be.

When conversing with Mr. John T. D. Llewellyn, of Ynisgerwn, Neath, some time ago on this very matter, he said that he had been troubled with the white mould in a few of his plants, and, on discovering it, had shaken all the soil from the roots and washed them in a very weak mixture of paraffin and water, and then repotted them; and he had found them do well afterwards. To the best of my recollection, he said he had mixed about half a tea-cupful of paraffin with four or five gallons of water, and he had found a little of this mixture given to some plants, the soil of which was so affected, had helped to kill it. Mr. Llewellyn had wisely confined his experiments to some common sorts, but he had been led to think it might be safely applied to choicer varieties. Mr. Llewellyn's experience had induced him to think that the white mould spreads more rapidly on the roots of plants allowed to become somewhat dry, and I am disposed to favour this theory, for two or three of my plants most affected with the mould had become very dry indeed, and the mould had spread with great rapidity.

Now that Auriculas are being repotted, the cultivator should take every precaution he can to prevent the growth of mould in any way. The month of May is undoubtedly the best time to repot, at the same time separating any plants that require it. A soft yellow loam with a kind of silken texture to the touch, as full of fibre as it is possible to be; some of the leaf-mould I have already described; some decayed stable manure, reduced by age to a black powder; and some silver sand, or finely-broken charcoal make up the compost I am this season using. The loam is not sifted; it is simply crumbled to pieces—being in the form of lumps of fibry turf—and none of the

fibre is taken out. Young offsets potted at the end of April are growing freely in this compost, root and leaf alike flourishing. At the time of potting I shake out the whole of the soil from the roots, shortening back the tap-root, or "carrot," as may be required, and then repot in thoroughly clean or new pots, giving them plenty of drainage. Generally I am putting the plants into smaller pots than last year, putting the strongest growers into the largest size. If by the end of August the more robust growers in the smaller pots need a shift, it is easy to give them one. There is much less danger from under-potting than from over-potting. Some of the plants Mr. Turner, of Slough, exhibited at the Southern Auricula Show in the Horticultural Society's Gardens in April last were in quite small pots, but they carried beautiful heads of bloom.

I am potting harder than last year; that is, the soil is pressed more firmly down about the roots. That they will find their way about among it, I have no fear. This is a great advantage in the case of young stock, as the soil does not dry so readily in drying weather as when it is lighter and more open. I think it is well not to use too light a soil in the case of Auriculas; I am this season using more yellow loam and less leaf mould, making the compost more adhesive. It is most important that there be sufficient drainage; a water-logged soil is certain to be injurious to Auriculas, and especially to the more tender varieties; i.e., varieties with a less robust constitution.

R. D.

THE SNOWDROP ANEMONE.

(A. SYLVESTRIS.)

Most of the Windflowers are beautiful, but this is one of the best, as it is comparatively dwarf, and very free as regards flowering, its

The Snowdrop Anemone.

pure white blossoms being as large as a crown piece when fully blown, and drooping gracefully when in bud. The foliage is elegantly cut into narrow segments, and is hairy underneath. This Windflower is a capital plant for the ordinary flower border, the lower parts of the rockery, or the margins of shrubberies, by the sides of woodland walks, in the wild garden, in all situations being quite indifferent as to the nature of the soil, provided it be not too dry. It comes from the groves and from hedgerows in many parts of South and Central Europe, where it presents a showy appearance during early summer.

W. G.

Drooping Star of Bethlehem in the Wild Garden.—This pretty species (*Ornithogalum nutans*) is one of the best for planting in the wild garden and similar places, as it is rapid and vigorous in growth, and scatters its seeds far and near, which grow freely, so that it soon makes effective masses. In the American Garden at the Fulham Nurseries it is now beautifully in flower, and the tall stems of drooping blossoms are very effective when in large masses, as seen here.—W. G.

YUCCA GLORIOSA IN TEXAS.

I WISH I could show you here a full-grown specimen of the *Yucca gloriosa*. It is quite common in this region, and is one of the first objects in the Texas vegetable world that attracts the attention of the new-comer from the more Northern States. The two very striking peculiarities of this *Yucca* are the leaves and its enormous bloom. So formidable are these leaves that the tree bearing them has received here the common name of Dagger Tree. As the tree increases in height the undermost leaves drop, exposing the smooth bark below them. It attains a height of from 12 ft. to 15 ft. So now you can imagine the appearance of this *Yucca*, as its head of great green swords, supported by the clean naked trunk, constitutes the entire tree. Sometimes the trunk branches out and supports several such heads as we have described, often so closely pressed together as to appear to constitute one gigantic crown of monstrous thorns. About the 1st of March a spike shoots upward from the centre, and here grow the flowers, an enormous plume sometimes 3 ft. long and 18 in. in diameter, and so compactly placed as to seem a solid mass. The ruling colour is a rich shining creamy white, which is varied by a light tinge according to the sub-variety. The tree itself is beautiful, and when it is surmounted by its glittering plume in such a gay contrast with its long bright green leaves, the *Yucca gloriosa* is certainly a prince in the floral kingdom. I have seen this flower at a full distance of two miles when circumstances were all favourable to a distant view.—"Gardeners' Monthly."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Potting Auriculas.—According to Mr. Douglas, *Auricula* potting for the forthcoming season should have been commenced a fortnight ago, but I think he is wrong in recommending this, because early potting is apt to produce autumn blooming, and any plant which blooms thus is weakened for the spring flowering. Old *Auricula* growers say it is better to let the plants grow on in shade for two or three weeks yet, during which time all shoots are to be taken from them and potted off; by this plan the plant acquires strength after its flowering, and is not likely to put forth blooms in the autumn. Perhaps Mr. Horner or some other northern authority would give his opinion on this point.—BROCKHURST.

Orbus vernus on Rockwork.—This old-fashioned early spring-flowering plant makes a charming subject for the rock garden, as in such situations it becomes dwarfed and more floriferous, and its many-coloured Pea flowers are seen to better advantage than on the ground; on rockwork, too, it blooms very much earlier. This plant might have been appropriately named *mutabilis*, taking into consideration the varied tints which the blossoms assume between opening and decay.—THOS. WILLIAMS, Ormskirk.

Effects of the Frost.—It may, I think, be roundly stated that almost all herbaceous plants which die completely down have passed through the winter unharmed. Of sixteen varieties of *Aquilegia*, including *cerulea* and *chrysantha*, I have not lost one. The same may be said of *Saxifraga*, but *Sedums* have suffered greatly, many sorts being entirely cut off. Mr. Williams, of Ormskirk, recommended *Mesembryanthemums* for rockwork, and I got *M. edule* and *Taylori* accordingly, but they are both dead; so are *Yuccas*, and, in short, all the succulent plants have suffered greatly. All the Gorse, Broom, and Heath tribes have been cut down, but many are sprouting again. Some large *Arbutus* shrubs which fruited here last autumn are quite dead. Of *Roses* I think only two are lost out of about 130 sorts grown here.—BROCKHURST, Didsbury.

Dates of Rose Shows.—I must differ entirely from "Cambrian" in his remarks on this subject. He has, by-the-by, made a great mistake in imagining that the date of the National Rose Society's Exhibition has been altered. The date of the Pelargonium Society's Show (to which the Royal Horticultural Society add a Rose show, a very different thing from the National) has been altered, and I think very unwisely. I have never known postponements to answer, whether in picnics, flower shows, or any other kind of arrangement. Plans have been made, persons arrange for them, and are consequently put about when the date is changed. In a flower show there is another objection; it may be done with the very best intentions, but there are always sure to be some people who imagine it to have been done to suit somebody. In the present case the inconvenience is already felt, witness the notice just above "Cambrian's" note; there must be a double examination of plants sent in for certificate of merit; and as to the postponement of a Pelargonium show five weeks before the date on the plea of weather, it would seem to me that the resources and skill of English gardeners must

be at a low ebb if they could not manage to overcome that little difficulty; and even as to Roses, I think it is all wrong. People are judging about the future condition of Roses from their experiences of the past few years. They were much more forward, but then came that cold wave about the 20th, with its frosts, which most materially checked their progress. This year we have had a long and dreary winter and cold spring. Roses were on the 13th, when the Royal Horticultural Society altered the date of their show, no doubt very backward, but since then a great change has occurred; the cold northerly winds seem to have left us, and the effect of genial rains and sunshine has been marvellous. We have had no such check about the 20th as we have generally had, and Roses, amongst other plants, have completely altered. I am astonished now (the 24th) to see the progress mine have made; not only can the buds be felt but seen protruding from the foliage; shoots have grown 7 in. or 8 in., and if this sort of weather continues, or indeed if we have no very decided check, as I think is not improbable, I am quite prepared to find that on this day five weeks Rosarians will say the National Society's day is not a bit too soon. *Nous verrons.*—DELTA.

New Zealand Flax.—I am glad to find from Mr. Baines' statement that the variegated variety of this Flax is likely to be even more hardy than the normal form, for if so it will be one of the most strikingly ornamental plants for outdoor decorative purposes in cultivation. Except in very favoured parts of England, I am afraid, however, from my experience of both forms, that neither will stand our climate without protection, but, fortunately, owing to their growth and general habit, this is an easy matter, as a few leaves or Bracken heaped around their collars are sufficient to shield the vital part, for if the crowns and hearts of the plants do not get injured they start away freely again in the spring. It is singular that the striped variety should be an exception to all other variegated plants as regards hardiness, that is, so far as our present knowledge of variegated plants goes, for, as a rule, they are tenderer than green forms, the leaves always suffering first and most in parts where there is the greatest absence of chlorophyll. This is very striking in cases in which the variegation occurs at the extreme margin of the leaves, the edges of which soon become affected by damp or cold, and frequently die off altogether. It may be that the *Phormium tenax* having bands of green running up the entire length of the leaves between the creamy-white gets better fed in that part, and, being less sappy through a more restricted growth, the severity of the weather has not so much effect upon it. Although the *Arundo Donax* proves quite hardy with us without any protection, the variegated kind gets killed, and will not succeed with all the coaxing we can give it, and I suppose it is equally unmanageable elsewhere, as I do not remember to have seen it, except under glass. It would appear, therefore, that the variegation has much affected its constitution, and not only is it so with that particular plant, but with all others with which I am acquainted.—S. D.

Haberlea rhodopensis.—The accompanying illustration of this plant is taken from a drawing of it which was sent to us by Herr Max Leichtlin, of Baden-Baden. We lately had occasion to refer to it on its flowering in Mr. Joad's garden at Wimbledon for the first time in this country. Apart from its beauty, it is highly interesting, as being one of the few hardy members of the family to which it belongs. This little gem comes to us from the Balkan Mountains, where it is found growing amongst Moss, &c., on damp, shady, steep declivities at considerable elevations; hence we may reasonably presume that it is perfectly hardy, though on account of its rarity it has hitherto been grown under glass in this country. It apparently thrives under similar treatment to that afforded to its congeners the Pyrenean *Ranunculus* (*R. pyrenaicus*), which in habit and general aspect it somewhat resembles. It has, we learn, been successfully imported in quantity to this country, and may be found in several of the London Nurseries.—W. G.

Lilium Batemannianum.—In the "Botanical Register" for the year 1839, Pl. 35, we have, I believe, the true *Lilium Thunbergianum*, flowered by Messrs. Rollisson the previous year. I doubt whether that was increased, or even saved; at any rate we have had for years past, under the name of *Thunbergianum*, many varieties of a Lily, all of them entirely dissimilar to the original both in flower and foliage. No one can doubt the characteristic accuracy of Miss Drake's drawing in "The Register," neither can we question the present figure with Dr. Wallace's description, but are not the two identical? and is not the recent introduction rather *Thunberg's Lily* recovered than a new discovery?—T. H. A. H., *South Devon*.

Primula cortusoides amona alba and **P. cortusoides**.—Of these I grow quantities; I have them both potted and massed in the border. In both cases they are mixed, and beautiful they look; a double row in pots in a small late Peach house is superb. Of those outside it may be said the blooms are not so clear, but they

possess a stoutness which makes amends for that deficiency. Several *Androsace*s have borne seed, and the same may be said of *Saxifraga Burseriana*. *Tritoma glaucescens* and *Uvaria* have surprised me. I thought they were killed, but they are coming up stoutly. *Roses* are badly infested with grubs.—J. Wood, *Kirkcaldy*.

Sparrows and Primrose Blooms.—If Mr. Groom (p. 392) has actually caught sparrows in the act with which he charges them, they must answer for their sins; for my own part, after much watching, I have never once detected a sparrow, but I have found the green linnet (*Loxia chloris*) to be the delinquent, destructive alike of Primrose and Polyanthus. My remedy (and a successful one) is string, with pieces of paper suspended immediately above the plants.—T. H. A. H., *South Devon*.

Narcissus pumilus.—This, I believe, is known and sold in some places as *N. minor*. However, from the description which I gave of the plant (p. 388), whatever may be its true name, it cannot be mistaken.—THOS. WILLIAMS, *Ormskirk*.

TREES, SHRUBS, AND WOODLANDS.

NEW SWEET-SCENTED RHODODENDRONS.

A VERY fine group of early flowering sweet-scented *Rhododendrons* has been raised by Mr. Isaacs Davies, of Brook Lane Nursery, Ormskirk, and they formed a remarkable feature in a large and interesting group of spring flowering plants, exhibited by Mr. Samuel Barlow, J.P., Stake Hill House, Slattocks, near Manchester, at the meeting of the Manchester Botanical and Horticultural Society on April 29.

Attention should be called to these sweet-scented *Rhododendrons*, for their excellent qualities are obvious. They are remarkable for a bushy habit of growth and marvellously free blooming character; the flowers are very large and of handsome shape, generally white, and here and there tinted with faint lines and streaks of bluish lilac; in addition they are richly fragrant, and remain for a considerable time in flower. Their being almost or quite hardy, except in times of unusual severity, they are easily cultivated, and invaluable for greenhouse decoration. One great recommendation is they are early bloomers, and come on early in cold houses without the assistance of artificial heat.

The plants shown by Mr. Barlow were in excellent condition, the most striking being one of the newest, namely, *Countess of Derby*. The flowers are of the purest white, bell-shaped, handsome in form, and deliciously fragrant; and so free of bloom is this variety, that quite small plants of it in 3-in. pots appeared as if they would break down under the load of flowers they bore. Next in point of merit comes *Lady Skelmersdale*, also bearing white flowers of large size, but of such a symmetrical appearance as never to be ungainly in aspect; quite a small plant of this shown singly in Mr. Barlow's collection had eleven trusses of bloom, and these contained on the aggregate between sixty and seventy flowers. *Countess of Sefton* has a bushy compact habit of growth, the flowers large, fragrant, cup-shaped, white, with a band of rosy-purple on each side of the corolla, which is handsomely fringed, imparting to the flowers a peculiarly attractive appearance. Mrs. James Shave, Duchess of Sutherland, and Miss Davies are all white-flowered varieties, the second of these three, like *Countess of Sefton*, having the flowers finely fringed; they are all distinct enough to form a collection, and are of great value as decorative plants.

These *Rhododendrons* are managed by Mr. Barlow in a very simple and efficient manner. He has a long span-roofed house, sunk below the ground level, in which he at certain times of the year cultivates *Auriculas*, *Polyanthuses*, *Lilies*, and many other interesting hardy plants; and here the *Rhododendrons* are kept during the summer after being potted when they have done blooming. They are potted in a compost made up of peat, sand, fibrous loam, and a little Cocoa-nut fibre, well mixed together. After being potted they make a free growth, which should be encouraged, as it conduces to the formation of good specimens. These *Rhododendrons* are not quite hardy, and should be protected from frost and wintry weather to ensure their being kept from harm. When the buds begin to swell, the plants can be removed to a comfortable greenhouse or conservatory to get them into flower early.

The freedom with which these sweet-scented *Rhododendrons* flower has a kind of chastening influence on the plants, correcting anything like a tendency to rampant growth. All the training they require is just sufficient to keep them to something like a handsome appearance, avoiding that tendency to tie in a rigid shape which is so common among some plant cultivators. R. D.

WATERSIDE PLANTING.

NOTHING adds so much to the charms of a landscape as the presence of a lake or a river, more especially if their margins be planted with trees and shrubs. Sombre masses of Conifers, the feathery forms of Birches and Willows, and the fiery autumn-coloured masses of American Oaks and Maples all contribute their share of beauty to such situations. It may be said that dark impenetrable trees or groups should find no place on south sides, because of the gloomy shadows imparted to the water when so situated. One of the items not to be overlooked in such planting is the hue which the trees assume in autumn, a point next to form. Amongst the many American Oaks which become beautiful in autumn may be named *Quercus rubra*, *Q. Catesbei*, *Q. ambigua*, *Q. palustris*, *Q. coccinea*, and *Q. tinctoria*. These flourish magnificently in moist ground, and, whether associated in groups or placed as solitary trees, yield charming effects, especially when hanging partly over the water. *Platanus occidentalis* succeeds well in such places. *Quercus pedunculata fastigiata* is effective either in the form of a group or singly; so also is *Celtis australis* by itself or associated with varie-

ties of *Alnus*. The *Celtis* is a good tree to plant where a rocky margin exists. *Catalpa syringefolia* succeeds excellently with its roots partly immersed in water, and when mixed with such subjects as *Thuja occidentalis*, or *Juniperus virginiana*, or some dark green *Pinus* as a background to set off its masses of white blooms, the effect is all that could be desired. In good soil it will reach a height of from 50 ft. to 60 ft. Of Poplars, such kinds as *Populus alba*, *P. alba nivea*, the different varieties of *P. balsamifera* (especially *macrophylla* and *grandidentata*) and *P. græca* are indispensable. *P. pendula* should be used with caution, as, if planted in quantity, it seems to impart a sense of sadness to the landscape. The Poplars look best planted in groups with rapid-growing Conifers. The

Tulip Tree succeeds admirably in moist situations, and its autumn tint is peculiarly pleasing. With American Oaks it makes a happy combination. There is a pyramidal variety which is useful for lightening up round-headed groups. *Juglans regia laciniata* is likewise a low-growing pretty tree, as are also the American Ashes, such as *Fraxinus juglandifolia*, *F. acutefolia*, and *F. longifolia*, the latter having foliage of a violet colour; *F. sambucifolia* is a tree with a most distinct character; also *F. lentiscifolia*. The pendulous kinds of Ash make good waterside trees, and the nearer they are planted to the water the better they look.

The Birches, such as *Betula alba*, *B. dahurica* vera, *B. grandis*, *B. lenta*, and *B. costata* make admirable small-sized groups or single specimens. Their only drawback is their inability to live long in such situations. Birches are perhaps most effective in groups planted thickly. *Acer dasycarpum*, with its reddish flowers and lacinated foliage, silvery beneath, should be found in every collection, as should also *Acer marginatum*, with its brilliant red autumn tint, *A. dissectum* syn. *palmatum* and *pseudo-platanus*, *A. tricolor*, and *A. Worleyi*, all of which are effective, and delight in moist ground.

Amongst trees of lower stature may be mentioned *Sorbus aucuparia*, the berries of which are pretty; also its variety *pendula*.

S. hybrida and *S. lanuginosa* are both fine-foliaged trees, the latter having a pyramidal habit and greyish colour. *Pyrus spectabilis* and its varieties make excellent single specimens, being beautiful both when in flower and fruit. *Hippophae rhamnoides* is a pretty low-growing tree, as are also *Eleagnus sativa* and *E. argentea*, both of which have neat grey foliage and bear small yellow flowers; they should not be planted in great numbers, at least, not in the vicinity of walks, their scent to many being unpleasant. The trees just named are certain to do well near water, provided the soil be not too unfertile; but the list of such subjects is by no means exhausted, and but few evergreens belonging to temperate climes have been included.

Moravia.

SYLVESTRIS.

CAMELLIAS AS HARDY SHRUBS.

MR. BAINES is usually apt to assume that he knew of the existence of any fact recorded in your columns forty years or so before any one who writes of it. His great experience, however, as regards Cam-

ellias is thrown in the wrong scale, and it is clear to me that he has not seen the shrub under the best conditions in the open air. Many know, as he does, that the Camellia is hardy even in northern gardens, but that it is not worth planting for its flowers in such places. But it is not known to many (and among them Mr. Baines) that over a large district in the south of England the Camellia is not only hardy, but that it flowers better than it ever does in pots, and that even this severe season has not in the least dimmed its beauty in the Isle of Wight and a large area of the adjacent coast region. In many a garden in this region the Camellia would prove the handsomest of all hardy flowering shrubs. To see these shrubs in flower, standing on lawns without a shred of protection,

and with even after severe storms many flowers in good condition, would do Mr. Baines' heart good, and be even more agreeable than calling up his long experiences.

S. W.

TREE PLANTING IN CANADA.

GREAT encouragement is now being given by the Canadian Government to emigrants in the North West to plant forest trees upon their farms, for though at the present time the long, rich Grass upon the prairies helps to retain the moisture, it is often found that sufficient rainfall for the successful cultivation of the land is not assured in districts denuded of trees by forest fires and other causes. The Dominion Parliament, therefore, is giving liberal grants of land to settlers, who secure an additional quarter section at a mere nominal price of about 10 dollars on the condition that they plant up the 32 acres by annual instalments. As an incentive to planting the example of an extensive Minnesota farmer has been quoted, who, two years ago, covered 72 acres with cuttings of Cotton wood, Poplar, and White Willows. These are now from 10 ft. to 14 ft. high, and in the most flourishing condition. The same planter put in several bushels of seed of Oak, Elder, Elm, Maples of various kinds, and Bass wood,

Haberlea rhodopensis (Frivaldsky). Balkan Mountains. A new Alpine plant; natural size; colour, delicate mauve-orange; throat with purple spots.

all of which have thrown up stems from 3 ft. to 5 ft. high. Belts of Oak, Ash, Whitewood, Tamarac, and Spruce skirt the banks of the rivers and streams. There are also considerable groves of Poplar upon the prairies, and this wood after being peeled is extensively used for fencing purposes. This and the soft Maple are very rapid in their growth, and the latter is considered one of the most valuable trees for shade.

The soil appears to be eminently fitted for the operations of the planter, as it consists of a black alluvial argillaceous mould, rich in organic matter, from 13 in. to 4 ft. in depth, and resting upon a strong clay. Its materials are, for the most part, finely pulverised, light and mellow. On the Red River twenty crops of Wheat have been grown in succession, without either fallow or manure, averaging 40 bushels per acre in good seasons. When land is selected for planting it is separated or enclosed by cuttings of the common woods of the district, which are inserted by the aid of a line to within two buds of their tops, and at an angle of from 30° to 45°. With clean cultivation during the first two years these cuttings soon form a barrier impenetrable to horses and cattle, and a valuable shelter to the after plantations. It is found that 10 acres planted in this way at 8-ft. distances will, at the end of five years, furnish all the fuel and fencing required for a large farm, and also realise a handsome sum from the proceeds of the sale of spare fence poles, which are sure of a market. The cuttings are planted as soon as the frost is out of the ground, and the operation is generally finished by the 1st of June.

To secure the planting of the land certain restrictions are placed upon the grant, of which the following are the heads:—

- 1.—The applicant (male or female) must be over eighteen years of age.
- 2.—That not more than 160 acres can be held by any one person for the purposes of forest tree planting.
- 3.—The land shall be open prairie and without timber.
- 4.—The applicant shall pay an office fee of 10 dollars at the time of application.

5.—At the expiration of six years from the date of entry the occupant is entitled to a patent for the land on proving to the local agent—

- (1).—That 8 acres of land entered had been broken and prepared for tree planting within one year after entry, an equal quantity during the second year, and sixteen additional acres during the third.
- (2).—That 8 acres of land had been planted with forest trees during the second year, an equal quantity during the third, and 16 more acres within the fourth year, the distance being 12 ft.
- (3).—That one-fifth of the land has, for the last two years of the term, been planted with timber and well regularly cultivated and protected from the time of planting.

By the offer of such liberal terms on the part of the Government it is believed that these vast prairie lands will soon be clothed with timber, which the care and foresight of the intelligent settlers will, in most cases, isolate from the destructive effects of fires.

WOODLAND WORK FOR JUNE.

THERE will in many districts still remain considerable quantities of bark to deliver, and even some trees to fall and strip. On the whole, the season has been one of the most unfavourable for such work which we have experienced for many years; the continuance of cold weather and frosty nights have so completely checked the flow of the sap, that but few trees have run well. No time or opportunity should now be lost in finishing the bark harvest and carting away the timber, faggots, &c., from the falls, after which a general clearance from the stools should be made and temporary roads cleared and stopped up for the summer. Bark in this district has realised from £4 5s. to £4 10s. per ton in the woods; but the falls of timber have on the whole been less than an average, and consequently the bark must be a short supply. In the case of recent falls it will now be necessary to look over the tillers and lighten the heads of such as are bent down by the weight of their foliage. These are sometimes numerous in fast-growing coppices, but timely attention will often completely restore them to an erect position. All injured branches of the store timber should also be removed by a clean cut close to the bole; and wherever damage has been done to the stools by wheels and the removal of timber, such should be at once trimmed off evenly.

As soon as time will permit, enclosing, draining, trenching, sub-soiling, digging, and pitting for autumn plantations may be taken in hand. Materials for fencing and road-making may also be carted where required, and composts formed in situations convenient for future use. A well-made compost is one of the most valuable auxiliaries of the planter, and no opportunity of collecting materials for such should be lost. Lime not only purifies and stimulates, but it also in the course of time enriches such admixtures of raw

materials. It formed one of the principal ingredients in the composts so largely used by Sir Henry Stewart, whose transplanting operations carried out early in the present century are among the most successful on record. Upon land infested with insects, and upon mossy lands and peat bogs after drainage, a heavy dressing of lime will render it unnecessary to pare and burn the surface.

Dig, hoe, or otherwise clean hedges, and trim such as are intended to receive another switching in the autumn. Also prune hedges of Furze or Gorse, Privet, and Elder, and look well after the boundary fences of woods and plantations, so as to keep out live stock of all kinds. Wire fences may now require tightening, and either painting or tarring. Where tar is used, select a hot dry day for its application, and let it be well rubbed into the wooden standards.

Large trees intended for removal in the course of a year or two may now be cleared, and opened out, and have trenches dug round them at distances proportioned to their spread of branches, so as to cut away their straggling roots. The trenches thus formed should afterwards be filled up with the best soil obtainable, and the spaces between the trenches and boles well mulched and lightly forked over. These operations will all conduce to the formation of abundant fibrous roots.

In the nursery great activity will be required to keep down weeds, to crop the spaces cleared of seedlings, and to dig and hoe in the lines. In dull weather seedling Evergreens may still be pricked out, but they may afterwards require watering and shading. Beds of Exotics should be protected until all danger of frosts is past. The bandages of forward grafts may be loosened, though the clay upon late made ones will still require attention, and perhaps renewal. Variegated Hollies may be budded and their stems cleared of superfluous branches.

The seeds of the Elm generally ripen towards the end of June. In gathering such select tall, well-grown trees, and be particular in the handling and storing of the seed, as it is very delicate and heats quickly. On this account it should be well spread out if not sown the same day on which it is gathered. When intended to remain in the beds for two-year seedlings, it should not be sown too thickly, as the plants are apt to become drawn up and weakly. A covering of $\frac{1}{2}$ in. of soil is sufficient, and this should be both rich and mellow. The seeds kept over for sowing in the following spring should be well and gradually dried before being stored away. An airy loft is the best place for storing them. The quality of Elm seeds may be ascertained by the firmness of the capsule.

THE BARK AND TIMBER TRADE.

OAK bark stripping in this locality is now well nigh over for the season, and in the southern counties generally it will be brought to a close at the end of this week. This year's strip of bark will be considerably below the average quantity, on account of the very low price which Oak bark is realising; it is, on an average, about £1 per ton less than last year. This I gather from returns received of recent sales throughout the country. The Government sale of Oak bark in the New Forest averaged £4 5s. 10d. per ton, this being £1 3s. less than last year, or £2 0s. 6d. lower than in 1877. At Stamford, on the 16th ult., Messrs. Richardson offered 245 tons of new Oak bark for sale by auction; but it appears there is little demand for bark in that neighbourhood, for out of eleven lots only four were sold, representing 60 tons, at the low average price of £2 12s. 6d. per ton of 20 cwt. in the wood; the other seven lots, representing 185 tons, were bought in at the reserve price of £3. On the Woburn Estate, Beds, this year's bark was sold for £4 per (21 cwt.) ton delivered at the railway station. In Sussex and other southern counties the price has been, on the average, about £4 per ton of 21 cwt. tied up into bundles and weighed in the wood. At Newport, and other parts of Shropshire, the price ranged from £4 to £4 5s. per ton of 22 cwt., delivered at the railway station or tan yard. The bark in this neighbourhood (Longleat, Wilts) has been sold for £3 10s. per ton of 21 cwt., put on waggon in the wood and weighed at the nearest weigh bridge, or £4 per ton delivered at the tan yard; these prices being £1 less than last year, and £2 10s. lower than in 1877. I do not think I ever experienced so great a depression in the bark and timber trade; the latter is equally dull, and prices of all descriptions of timber are down, with perhaps one exception, and that is for well-grown copse Ash, there being still a demand for clean butts at a good price. The fall of timber throughout the country is sure to be less than in former years. I have no doubt that the timber trade will improve in another season or two, and in the meantime landowners would be wise to only cut such timber as is a necessity until the demand is greater than at present. On this estate we intend to make the cut short until timber, bark, Underwood, and faggots yield better return.

GEORGE BERRY.

Longleat.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Remarkable Rhododendrons.—Among the Rhododendrons now in flower at Glenville are two plants of the *R. altacense* remarkable for their size and the profusion of their bloom. One, the largest of the two, stands close upon 20 ft. high, and is 80 ft. in circumference at the base, where the branches rest on the Grass; higher up it is of greater circumference. It is a mass of flower from bottom to top and on all sides, as the plant stands free of other trees. It would be next to impossible to count the trusses of bloom. The other is about 17 ft. high and 40 ft. in circumference. There is not one shoot on this plant that does not carry its truss of flowers, and at a short distance off it appears an unbroken sheet of crimson. As in the other case, the trusses could not be counted, and there cannot be less than 1000 on it. This, though an old variety, is a most desirable one to grow, as it is of free growth and a constant bloomer. Amongst the rarest Himalayan varieties in flower are Aucklandi, with eighteen trusses of beautiful rose-shaded white flowers; *R. cinnabarinum*, with over eighty rich crimson blooms; *Windori*, a rich scarlet, flowering for first time at Glenville, though the plant is a large and vigorous one. All who grow Rhododendrons should certainly grow Aucklandi, for beyond doubt it is the most beautiful of the tribe, and has a highly agreeable perfume. It is perfectly hardy, too, as its natural habitat is over 7000 ft. elevation.—“*Irish Gardeners' Record*.”

Bird Cherry (*Prunus Padus*).—There are many huge spreading bushes, or rather trees (for some of them are upwards of 40 ft. high, and as much or even more through), of this beautiful free-flowering and sweet-scented Cherry growing in different parts of the woods at Longleat, and just now their masses of blossom are everywhere conspicuous. This being one of the freest flowering, hardiest, and most easily cultivated of trees, the wonder is, that it is not more plentiful everywhere than it is. Numbers of it grow hereabouts in the hedges, scenting the air at a time when there is hardly another hedge shoot in bloom. Lilacs, too, are becoming plentiful in the hedges, and their blooming period quickly succeeds that of the wild Cherry. Laburnums, Hawthorns, and Lilacs bloom about the same time, except perhaps the Scotch Laburnum, which is about a fortnight later than the common variety. Liberal quantities of all these have been distributed about the hedges, so as to secure a succession of blooming plants until well into summer. Nor must I forget the sweet Briar, with which many gaps in the hedges have been filled up.—G. B.

Camellias in the Open Air.—I am at a loss to understand why the blooms of the Camellia should be regarded as more tender and more liable to damage from wind and rain in the open air than those of the Rhododendron, Azalea, and other hardy early-blooming shrubs. Are there not times when storms damage these? But will anyone assert that because of that misfortune neither Rhododendrons nor Azaleas should be grown out-of-doors? Those who have had experience of the Camellia in the open air know that for one bloom that may be damaged by the weather twenty or more are produced clean and beautiful. The growth of the Camellia is stiff, and its foliage hard and leathery; therefore the wind exercises less effect upon it than upon many other flowering shrubs. A daily paper announces that a Continental nurseryman is going to plant on one of the railway banks at Kilburn 100 Camellias, to be in flower next July during the Agricultural Society's exhibition. This will be a novelty, indeed, and might help to stimulate the cultivation of the Camellia as a hardy shrub.—A. D.

Spiræa Thunbergiana.—This is just now in full bloom. Several plants of it which I put out in the woods are now from 4 ft. to 5 ft. high, and form effective bushes. It is altogether a superior deciduous shrub, but not the dwarf plant “*W. G.*” seemed to infer it is when he said that it grows about 2 ft. high. I have several plants of it in the nursery as well as those planted out in the woods, and I believe that in a few years they will be from 6 ft. to 10 ft. high, and as broad as high if allowed their full development. It is a very distinct and pretty Spiræa, one of the earliest to bloom, and not easily mistaken for any other variety; its small lanceolate leaves, and slender twigs clothed with white Hawthorn-like flowers, at once distinguish it.—G. B.

Buerger's Evergreen Oak (*Quercus Buergeri*).—The list of cultivated kinds of Evergreen Oaks is not large, and this handsome species is such a desirable addition that it well merits a passing note. It forms a tree or large shrub of noble, spreading habit and free growth. The leaves are as large as those of the common Laurel, but of a deeper green, and far more effective. In form they are ovate and pointed, and leathery in texture. It is perfectly hardy, having withstood the past winter with impunity, and now forms a fine feature amongst other shrubs in Messrs. Veitch & Son's Nursery at Coombe Wood.—W. G.

VEGETABLE CULTURE FOR MARKET.

FRENCH BEANS.—When Peas and Broad Beans begin to get comparatively scarce these are always welcomed. They always command a sale, provided they are good and fresh, and overstocking the market with them is almost a thing unknown; but when large quantities of them are introduced prices are of course affected. Under any conditions, however, and all through the summer, a good crop of Beans is a profitable one, and where soil and situation are at all suitable, market growers cultivate French Beans in large quantities. The principal kinds grown are the Newington Wonder and Long-podded Negro, which, although old varieties, are reckoned to be the two best. Their productive qualities are great, for when well attended to as regards timely picking of the pods, they continue fresh, vigorous, and fruitful for a long time, and their pods, as a rule, are less apt to turn tough and unusable with age than is the case with some varieties. The Black Belgian has also found its way into the market gardens; it is a good, dwarf, early sort, much like the Negro, of which it is considered to be a variety. It is very useful for late sowings and for early framework. Some growers prefer the Newington Wonder to all other sorts; it is a very prolific, dwarf-growing kind. Other growers prefer the Negro, which they grow in frames, for their earliest, main, and latest crops; but most of them also grow the Newington Wonder. The Canadian Wonder or Red Flageolet is a comparatively new kind, and one which will doubtless be grown largely for market. It is a robust grower, a good cropper, and its pods are as large as those of a Scarlet Runner and of good quality. Early crops of French Beans are grown in frames, such as have been cleared of Cauliflower and Lettuce plants; the mould in the frames is pointed over with a spade, and the Beans are sown in four rows under each light, and about 3 in. or 4 in. from seed to seed in the row when the soil is dry. The middle of March is the common time for sowing in frames, and then the sashes are kept close till the seeds have germinated, when they are tilted up a little at the back in favourable weather, but care is always taken to keep them close in the case of cold winds, and to cover them over with mats or litter in the event of frost. As the plants advance they are treated more hardily, but judiciously, judging according to the weather. After the middle of May, when all fear of frost has passed, the sashes are entirely drawn off throughout the day, if fine, and replaced at night. Whilst growing plenty of water is given them at the roots, and picking commences about the second or third week in June, or about three weeks sooner than the earliest border crops come into use. A few frames, too, are also frequently occupied by French Beans sown thickly, for the purpose of transplanting thence to the open ground, and to fill any blanks that may exist in the frames in which the sowings for fruiting therein have been made.

The first outdoor crop is usually transplanted from such frames, and the warmest possible position is selected for this purpose; the time for so doing entirely depends on the state of the weather and nature of the ground. If the weather be fine, the soil moderately dry and light, and the position warm and sheltered, the plants are commonly transplanted during the first fortnight of April, but if otherwise, they are delayed a little later. They are then lifted with as much earth adhering to their roots as possible, and are planted in little patches under hand-lights. The usual way is to draw lines 3 ft. apart across the border, others 2½ ft. asunder lengthways, and upon the middle of every little square thus marked place an ordinary hand-light, under which plant six or eight plants. If there be not sufficient hand-lights for the whole space to be planted, half-bushel vegetable baskets are

inverted over the plants ; and, as they are so open to the wind, they are sometimes covered for a time with mats. As soon as the Beans have got a good hold of the soil and begun to grow, their protection is removed. Great care must be exercised with hand-light Beans, otherwise they are a deceptive crop, and sometimes die off altogether, especially when nursed too tenderly and changed too suddenly, if the ground be cold and wet, and their top covering insufficient. Those grown in frames, and which come into bearing early in June, last in good picking condition for six weeks ; and those in warm borders begin to fruit in the last week of June or first week in July, and continue to yield a fair crop for nearly two months in a moderately moist season, if kept closely picked. The first main crop immediately follows the border ones, and, as a rule, lasts the longest. Drought makes them short-lived sometimes, but in rich soils, and warm, moist seasons, the yield is so heavy that it is scarcely possible to pick them as quickly as they grow. Drought, too, induces red spider, with which large fields are sometimes completely overrun ; and although this pest is very prejudicial to the health and longevity of the crop, there is no remedy for it.

The valley of the Thames is unequalled as regards the growth of French Beans ; the soil is not liable to excessive drought, and it is made light and rich by much working and heavy manurings. French Beans are gross feeders ; they require manurial substances of such a character as can be speedily turned to account ; therefore, land that was richly manured for the previous crop—such as for Celery—and which has afterwards again been liberally dressed with short manure, such as that from Mushroom beds or old Cucumber pits, suits them perfectly. The crop to succeed such as are grown under handlights is planted on a south border, in front of a wall or thick hedge if possible, which is dug over and lined off in cross-rows at 18 in. apart, drawing the lines in the form of seed-furrows with a hoe. Herein are planted Beans 5 in. asunder in the row ; they are earthed up in due time, and, if the weather be favourable, come into bearing three weeks after those grown in frames. Some growers erect barricades of mats in an upright position to stakes driven in the earth, and placed to the windward side of the borders ; and they also surround frames containing them, but not covered with sashes, with the same protection to ward off cold and frosty winds. Sowing begins out-of-doors during the first fortnight in April, just as the state of the weather and soil permits, and the warmest available position is selected for the purpose. If the ground be free from all other crops at the time of sowing, there is more need for a sheltered place than if it were cropped. In sowing, the lines are drawn at 2 ft., 2½ ft., and sometimes at 3 ft. apart, and the seeds planted about 4 in. or 5 in. asunder. The earliest crop is often sown in drills drawn between lines of Cauliflowers, Cabbages, or Lettuces. These crops, instead of being injurious to the French Beans when they appear aboveground, are simply beneficial to them, inasmuch as they protect them from cold winds until they have gained some strength and the weather becomes mild and warm, by which time the bulk of the Cauliflowers will have been removed for market. Even then, however, the Beans do not get all the space to themselves, for no sooner is the earth cleared of the other crop, than it is loosened a little between every alternate line, and those spaces replanted with Lettuces or similar crops. Thus one space contains another catch crop while the other is empty ; and by means of having this empty space to walk in, the women can pick two lines of Beans, one on either side of the empty alley, and never disturb the other crops in the alternate alleys. Should the French Beans have come up well, and be nearly ready for picking before the first occupants of the soil are entirely removed, the alleys are

not cropped again until they become exhausted. The drills for sowing are drawn in the morning of a fine day and left until the afternoon, when seeds are sown and some earth drawn over them. The first main sowing is made on the open field about the second or third week in April, under the same circumstances as that already mentioned, or the field may have been previously planted out with Cos Lettuces in lines 12 in., 15 in., or 18 in. apart ; between every two lines of these would be sown one of Beans. Along both sides of Asparagus ridges Beans also often find a place.

Some growers sow late crops in rows 4 ft. apart, and plant two rows of Coleworts in every intervening alley. Before the seeds appear the soil immediately over the seeds is gone over and slightly loosened with an iron-toothed rake so as to permit of an easy egress of the seedlings. When sown in bare fields, even though Lettuces be planted amongst them, a little ridge of soil is frequently drawn to the north or windward side of them as an additional protection from cold winds. Whilst the plants are growing they are rigidly attended to as regards keeping them clean and hoeing the soil, and when they reach 4 in. in height they are earthed up a little. The catch crops, too, are, cleared away as soon as they are ready, in order to give the French Beans every opportunity of a healthy development. Successful sowings are made every fortnight or three weeks, until the end of June, by some growers, but most of the large growers sow their French Beans about the 8th and 20th of April, the first and last week in May, and the first week in July. The last sowing consists of the Negro, and just yields a good crop of young and fine pods' before being destroyed by frost ; whereas, were they sown a fortnight later, they would be apt to be nipped when coming into bloom. Gathering is well attended to, for if full-grown pods be allowed to remain too long on the plants the latter soon cease to bear. The Beans are gathered by women into baskets, which, when full, they carry on their heads to the ends of the rows, there to leave them to be carted home, where they are washed to remove the grit. They are then packed into round half-bushel vegetable baskets, which are covered with Rhubarb leaves fastened down with withies, and piled one above another on the waggon that convey them to market three times a week. Most market gardeners save their own seeds, and a piece of the main sowing is generally selected for this purpose. The plants in the rows to be saved for seeds are first subjected to two or three pickings for market ; then they are left untouched until the Beans are fully ripe, when the plants are pulled up by the roots, tied into little bundles, and slung in pairs across a fence or rail to dry. Sometimes, too, the haulm is spread over sashes to dry, and, in the event of wet weather, is strewn under some spare sashes, where it gets well dried without receiving any of the rain ; it is sometimes spread out over a series of sashes resting on frames, and other sashes laid over it again, and tilted up at back and front, so as to permit of a free current of air, where the seeds dry readily. They are then housed, and during wintry weather are thrashed, cleaned, and stored in rough brown paper or canvas bags, or placed in drawers, or the corner of a loft, until sowing time arrives.

SCARLET RUNNERS.—These, on account of their taking up more room, are not so largely grown near London as the dwarf French Beans. Their yield is not so great in proportion to the ground occupied, and they are also, unless supported by stakes, more difficult to gather. Round Wandsworth, and in some parts of Kent, within 20 miles of London, however, large fields are devoted to their culture. In some places stakes are used, but, as a rule, the points of the shoots are kept stopped, and the haulm is allowed to rest on the

ground. In some respects this latter practice is best, for the rows can be placed close together, and, moreover, the haulm shades the ground and keeps the soil moist, a condition essential to the growth of Scarlet Runners. A rich, light soil and an open situation is that usually chosen for them. Some plant a few rows in warm, sheltered places for early use, the seeds of which are sown in a temporary frame in April, and are transplanted from thence to the open ground as soon as the weather is warm enough to admit of it, but, as a rule, the seed is sown in drills in an open field about the first week in May. Ground previously occupied by Celery suits these Beans perfectly, the soil being deep, well worked, and rich. The seeds are sown in broad drills from 4 ft. to 8 ft. apart, according to whether the plants are to be staked or not. Two rows occupy each drill, and the plants when up are left from 4 in. to 6 in. apart each way, the thinnings being used to fill up gaps, should such occur. When the plants are fairly up a ridge of earth is drawn to each side of them to protect them in some measure from cutting winds and late frosts. When in full flower the points of the shoots are pinched off, an operation which causes the stem to branch out and grow dwarf. In gathering, the Beans are first put into sieves, which are carried to the end of the rows to be packed in bushel baskets; the latter are removed to the packing shed, where a little long Grass is placed over their tops, and kept in its place by means of Hazel rods; they are then placed in waggons and sent to market. Early in July Scarlet Runners appear in Covent Garden, and when that happens French Beans are not in so much demand as hitherto, the majority of vegetable consumers preferring Runners to French Beans. Some market gardeners sow successional crops for autumn use, but the bulk of the produce is brought to market in the end of July and throughout August. Their general culture is the same as that followed in the case of French Beans.

THE CABBAGE.—This is one of the most important of green vegetables, and although not considered by many so profitable as some others on account of its gross feeding character, it comes into use when there is little else to send to market, and often realises high prices. In the spring of the year many acres of Cabbages may be seen about Wandsworth, Fulham, Gunnersbury, and, in fact, all round the suburbs of London. The Cabbages sent to market in April, May, and June are the produce of seed sown early in August, and the plants are put out in September or early in October. Succession crops are sown in spring as soon as the weather is favourable. If sown too soon, as is sometimes done, the young leaves get injured by frosts, especially if these occur immediately after a period of mild weather.

The Enfield Market Cabbage is that which is principally used in the market gardens about London. It is one of the oldest in cultivation, and one of the best, and for this reason the growers generally save their own seed, and take great care that their plants of it are not crossed with other sorts. The sowing for the principal crop of this Cabbage is generally made between the end of July and the middle of August, on poor ground if possible, as in that case the plants come up stocky and hardy, and stand the winter well; whereas, if made on rich ground, a soft rank growth is produced, which is much more easily injured. This sowing is, as a rule, made in 4-ft.-wide beds—a width found to be convenient for weeding and hoeing amongst the plants. When sufficiently strong to be transplanted, they are planted on ground cleared of Onions or Potatoes, and a second batch is planted on land cleared of Celery, French Beans, or Vegetable Marrows. Every empty space, under fruit trees or elsewhere, is also planted with Cabbages. In planting, the ground is lined off into rows 30 in. apart, and in these the plants are put in 15 in.

asunder. Between every two rows first planted another is now put in with less care, thus making the plants stand 15 in. apart each way. Early in spring every alternate line of plants, and also every other plant in the lines or rows left, are lifted and sold as Coleworts. This allows the permanent crop plenty of room to come to maturity. With a view to subsequent plantations, which are made all through the winter wherever ground is vacant, the young plants in seed-beds are removed and pricked out into others a little further apart, in order to keep them in good condition for planting out as long as possible. In this way, indeed, many of the plants are kept till spring, when they are transplanted to succeed those planted out in autumn, and to come in before the produce of the spring sowings, made late in February or early in March, to furnish Cabbages from June to August. The plants from this sowing are put out in rows 2 ft. or 2½ ft. apart, and in the intervening spaces are put lines of Lettuces, a plant of which is also set between every Cabbage in the row. In May may be often noticed men busily engaged in tying up early Cabbages in the market gardens at Fulham and elsewhere. The operation is simple, just, in fact, that adopted in the case of Cos Lettuces. The succulent outer leaves are folded carefully around the heart or centre of the plant, and the whole is bound firmly with a withe or piece of bast. There are several good reasons for this practice. The centre being protected from the weather, the Cabbages heart sooner than they otherwise would do, and they are more easily handled in gathering and packing for market. Early Cabbages, the leaves of which are so brittle, would lose half their value if some precaution of this kind were not taken to keep them from being broken by loading and unloading them. Red Cabbages are sown in March, and the plants are put out in rows from 3½ ft. to 4 ft. apart, and the plants stand about 3 ft. asunder in the rows. As this crop stands until the heads are large and solid, a piece of rich land is devoted to it, and intercropped with Potatoes, ordinary Cabbages, Lettuces, French Beans, or other vegetables of that kind. The produce of the July sowing is generally considered better than that of spring.

COLEWORTS.—These are Cabbages pulled for market when about half grown, and for supplying such, every spare corner in market gardens is planted. As soon as fruit bushes have been cleared of their crops rows of Coleworts are planted between them; they are also planted under fruit trees, no matter how large the trees may be, and also between rows of Moss Roses. The space between Celery ridges is likewise generally planted with Coleworts, as is also that between Asparagus ridges, the edges of which, too, are often cropped with Coleworts. Between the rows of French and Runner Beans and late Savoy, the Colewort is also planted, and, in fact, like Lettuces, it is planted in every empty space where there is a probability of its growing. Whole fields, too, are sometimes cropped with it, and are cleared in good time for winter Radishes. Cock's Hardy Green Colewort more resembles an ordinary Cabbage than the Rosette, which is grown largely for market, and, being hardier, is sown a month or six weeks later, so as to form a succession to that sort. A sowing of the Rosette is usually made in May in beds in an open piece of ground; and, when up, the young plants are thinned with small hoes. The strongest plants are first selected for transplanting, and are put in chiefly as catch crops between other vegetables. For spring Coleworts, only the thinnings of the Fulham Cabbage are used. The Rosette is, perhaps, the greatest favourite in the market, its beautiful white heads, when bunched, having an attractive appearance; but, as regards quality, nobody would eat the Rosette who could get Cock's Hardy Green—i.e., if they were acquainted with the respective flavours of the two varieties. A kind

called Blue Colewort is largely grown for a November crop, as earlier in the year it is apt to "bolt." Coleworts are tied in bunches, packed in waggons, and sold in this way in market.

SAVOYS.—These are not so much esteemed as Cabbages, but they are largely cultivated by some growers. The seed is sown in March, and the plants are put out under trees or in similar positions in the same way as Cabbages. The varieties grown are the Dwarf Green Curled, Early Ulm, and Drumhead. Sometimes they are used as Coleworts when half grown, in which case they are planted thickly among other crops in any vacant places in the same way as Cabbage Coleworts. During winter when greens are scarce Savoys are most in demand. They are very hardy, and are all the better for being subjected to frost, and for this reason they are a good winter crop. The refuse of the seed beds are sometimes planted out in August to supply Coleworts in winter and spring.

BRUSSELS SPROUTS.—These are chiefly grown in market gardens as catch crops, under orchard trees, or between other vegetables. The seed is sown in April, and the plants, when large enough, are put out wherever a vacant piece of ground occurs. Market gardeners prefer Brussels Sprouts with medium-sized stems to those of rank growth, as from these they get harder and better Sprouts, which realise the most money in the market. In gathering Sprouts most market gardeners pull up the plants and cart them to the packing shed, where women divest the stalks of the Sprouts and pack them in $\frac{1}{2}$ bushel or bushel baskets, the largest and plumpest being always put on the top. The Cabbage-like tops are packed separately in large baskets. Some growers, however, pick the Sprouts from the plants as they grow and leave them to supply another crop. Brussel Sprouts when in the seed bed are often attacked by small white-winged flies, which congregate on the underside of the leaves and greatly injure the plants. In order to get rid of these, an old sack is nailed to two poles, about 6 in. being allowed to hang over one of the poles to act as a flapper. The sack, but not the flapper, is then tarred all over, and two men, one each side the seed bed, walk quickly along with the sack directly over the plants. The flapper drags over the plants and disturbs the flies, which fly upwards and get stuck to the tar. This operation several times repeated gets rid of the majority of the insects. C. W. S.

Early Mint.—On warm sunny beds in the shelter of a north hedge some of the market gardeners are gathering fine shoots of Mint for sauce and other culinary purposes. Such a position, both warm and still, in so far as it is unvisited by rude northerly and easterly winds, is as good as a cold frame. The beds are made light in the character of the soil, and above the ground level in September, after it has been deeply dug and well manured, and very early in the spring, the Mint peeps through the surface, and according to the weather so is the growth made. It is remarkable what a growth has been made despite the cold weather. Many put their Mint away in the coldest and shadiest parts of the garden, where it is certain to be late, and the few remarks made under the above heading show how this practice can be improved upon. A well-managed market garden supplies many valuable cultural hints.—R. D.

The Water-cress (*Nasturtium officinale*).—This is one of the most wholesome of our wild plants. It is useful in salads, as a relish at breakfast, tea, or supper; and as an esculent with salmon nothing surpasses it eaten with a little vinegar; but how completely is its cultivation neglected in this country, whilst tons of it are sent into Paris in the course of twelve months! But what one most regrets is the recklessness in operation amongst people—men, women, and children—who go to the clear purling brooks in the country to gather this Cress; their usual habit is to rake out the fine, long, and strong stems, with their rootlets, &c., and leave them on the banks to wither and die, after having pinched off the young shoots. The stems should always be thrown back into the stream to reproduce

young shoots. I have known some, yet many, localities where this useful esculent used to grow in abundance, but whence it has been entirely destroyed by this carelessness. In pinching off the young shoots, two or three of the leaves nearest the stem should be left, because from the axils of these leaves the young shoots are produced. In gardens through which a clear stream meanders Water-cresses should be established, as they would become profitable to the possessor and a boon to the neighbourhood.—W. B. C.

PLATE CLXXXII.

BROWNEA MACROPHYLLA.

Drawn by MISS TRAVERS.

The genus *Brownea* consists of small evergreen trees belonging to the Leguminosae, and to that section having regular corollas. The species are peculiar to Venezuela, New Granada, and some portions of Central America, one of them being also found in Trinidad. The leaves are alternate, equally pinnate, and from 1 ft. to 1½ ft. long, with from four to twelve pairs of entire leaflets. The flowers are flame-coloured or crimson, and disposed in dense, sessile heads. It would be difficult to point out a more beautiful genus than this, and in few places are *Brownias* grown in such perfection as at Lakelands, the residence of Mr. W. H. Crawford. Here *B. macrophylla* bloomed for the first time in the United Kingdom, and only at two other places has it flowered in Europe. This is the third year in which it has produced its beautiful blossoms in succession at Lakelands, and this year its blooms, though retarded in their development, possibly by the severity of the winter, were produced when they did begin to expand in greater profusion than ever before, and were scattered all over the tree from within 1 in. of the ground to the extreme points of the young growth of last year, as many as eighteen of these gorgeous heads being in full beauty on one and the same day in April. Each blossom-head only lasts in beauty for a couple of days, the petals falling on the evening of the second day after expansion. Another variety named *B. latifolia*, nearly as handsome as the variety figured, but much sayer to bloom, also flowers occasionally at Lakelands, as well as *B. grandiceps*, *B. ariza*, and *B. coccinea*, the latter comparatively small and insignificant in size though brilliant in colour, and of a deeper shade of scarlet. Mr. Crawford hoped to have bloomed a plant sent to him as *Brownea erecta* last summer, for the flowering of which he had been waiting patiently for many years, but when the tree bloomed it turned out not to be a *Brownea* at all, but *Talisia megaphylla*, a plant which bears myriads of small, fluffy white flowers on a candelabrum-like scape. W. E. G.

Camellias in Boxes.—"Cambrian" states (p. 414) that Camellias in boxes need little attention for many years, but I think they may be benefited by a root examination and fresh soil every third year. With this object in view my Camellia boxes are made so as to let down the sides, in order that fresh soil can be added, and the roots pruned at pleasure. A skilful carpenter will easily plan this when making the boxes.—BROCKHURST.

Anemone fulgens and its Varieties.—Messrs. Barr & Sugden have sent us flowers of a large variety of *Anemone fulgens*, ranging in shade from brilliant scarlet to a luminous crimson, and with the usual conspicuous black tuft in the centre, the flowers ranging in size from 4 in. to 5 in. in diameter. *Anemone fulgens* and its varieties will doubtless occupy a conspicuous place in our gardens now that they have become more plentiful and comparatively cheap. This plant appears to afford considerable variety, and from seed it is probable that ere long we may have a section in which are some good representatives. The kind here alluded to is *A. fulgens grandiflora*. Then there is the typical *fulgens*, of uniform scarlet with black centre; then *fulgens annulata* and *fulgens oculata*. The form *multipeta*, with from twenty to thirty petals in number, is also a very desirable kind. *A. f. annulata* and *A. f. oculata* are no doubt the single forms of the double Peacock *Anemone* so abundant at Cannes and elsewhere; at least, they are found flowering amongst the double ones, and if the petals of the double variety be carefully examined, the yellowish-white ring and eye can be distinguished. The inference may, therefore, fairly be drawn, that the double Peacock *Anemone* is a form of *A. fulgens*. In addition to *Anemone fulgens*, we understand there is a rose-coloured variety.

Dendrobium Dalhousianum.—We noticed a fine specimen of this beautiful but shy-flowering Orchid a few days since in the collection of Mr. A. C. Stearn, Radnor House, Twickenham, bearing a dozen spikes and over fifty flowers of large size and very distinct as regards colouring.—W. G.

GARDENING FOR THE WEEK.

Ferns.

Elegant as most Ferns are, still there are some that are very much more so than others. Of late years the fashion has usually been to give preference to the larger-growing species to the exclusion of many of the smaller kinds; but that is a mistake, inasmuch as where there is a preponderance of the strong-growing species, they occupy a good deal of room, proportionately reducing the accommodation available for a greater number of varieties to which more interest will be attached. So many charming and distinct kinds grown some years ago are now so seldom met with, that a short list may not be out of place. Amongst *Adiantums* the old *A. cuneatum* is such an established favourite, that it generally finds a place; indeed, there is scarcely an indifferent species in the whole family, but the following are particularly deserving of culture, viz., *A. caudatum*, *A. cultratum*, *A. eximium multifidum*, *A. pentadactylon*, *A. scabrum*, *A. tenerum*, *A. Veitchi*, *A. reniforme*, *A. scutum*, *A. Farleyense*, and *A. gracillimum*; the last two, especially *A. Farleyense*, do a great deal better grown much cooler than they usually are. *Aspleniums* of medium growth may consist of *A. Belangeri*, *A. bulbiferum*, *A. Hemionitis*, and *A. lucidum*, all of which are distinct and handsome. Most of the *Cheilanthes* are extremely elegant, especially *C. tenuifolia*, *C. lendigera*, *C. frigida*, *C. fragrans*, and *C. dealbata*. *Davallia Nova-Zelandica*, *D. immersa*, *D. bullata*, *D. dissecta*, and *D. canariense* are good; and of *Gymnogrammas*, select *G. tomentosa*, *G. lanata*, *G. rufa*, *G. tartarea*, *G. Mertensii*, *G. peruviana argyrophylla*, and *G. chrysophylla*. The elegant climbing *Lygodiums* are always desirable; amongst them *L. palmata*, *L. scandens*, *L. circinatum*, and *L. flexuosum* are all handsome. Amongst *Notholaenas*, which are nearly allied to *Cheilanthes*, may be named *N. Eckloniana*, *N. trichomanoides*, *N. vestita*, *N. sulphurea*, and *N. nivea*. Of *Polypodiums* I would recommend *P. appendiculatum*, *P. lingua*, *P. musefolium*, *P. plumosum*, and *P. subauriculatum*. Amongst *Pterises* the well-known *P. cretica* is one of the best greenhouse Ferns in existence, and all but hardy, and the same may be said of its variegated form *P. albo-lineata*; the old *P. serrulata* is a most useful kind for cutting, and amongst its many of the crested forms *P. serrulata* *Levyi*, *P. s. Dixoni*, and *P. s. corymbifera* are well worth growing; also *P. scaberula*, *Leucostegia immersa*, and *L. charophylla*. Many consider *Todeas* difficult to cultivate; but they are not so if kept sufficiently shaded and moist at the root in a moderately close, moist atmosphere and always cool; greenhouse temperature is quite sufficient for them. The best amongst them are *T. superba*, *T. intermedia*, *T. Wilkesiana*, and *T. Fraseri*. These are only some of the many comparatively small Ferns that are deserving of cultivation. I have not attempted to divide the greenhouse from the stove species, as, excepting the *Gymnogrammas*, all may with advantage be grown with less heat than that to which Ferns are often subjected.

Gleichenias.—These are of larger but not coarse growth, and even in the most select collections a few of the best *Gleichenias* should be grown; the more beautiful and distinct are *G. rupestris*, *G. Spelunca*, and *G. flabellata*.

Platyceriums.—*P. grande* is the finest of all; it requires a little more warmth and a closer atmosphere than the others. *P. Stemmaria* is also a handsome and interesting plant, although its shields are not of the evergreen character of those of *P. grande*. Grown as they often are on blocks of wood, with comparatively little matter for their roots to run in, *Platyceriums* require more atmospheric moisture, as well as more attention, in regard to watering than when in pots; but when cultivating them in pots I have found it best to invert the pot, securing it on to a stout piece of wood, acting as a plinth; I then knock the bottom (now uppermost) out, and while in this position fill the pot one-fourth full of drainage, the remainder being peat corks and a little sand, such as would suit the generality of Orchids. I set the plant on the top with its roots inside, and secure it with a couple of sticks inserted within the pot; the pot being upside down is more favourable to the development of the shields than if it were in its usual position. These *Platyceriums* must never be exposed to much sunshine, and on no account must they be allowed to get dry, and they must be kept scrupulously clear from thrips, which are very partial to them, and which must be destroyed by moderate fumigation, as when the growing fronds are affected with these insects they will not bear touching with the sponge, in fact so delicate are they when in a tender, growing state, that even a slight accidental rub with the hand will stop them from fully developing.

Orchids.

Treatment when in Flower.—Independently of the large general collections of Orchids that now exist in so many places, there

are large numbers who cultivate only a limited quantity of these plants, and in such establishments it frequently happens that the plants when in flower are set for a time in conservatories, halls, and other places, which, in addition to interfering materially with the season's growth, are calculated to do permanent injury to them. This especially happens in the case of the thick-rooted true air plants, a large portion of the active roots of which are above the soil and fully exposed to the air, and consequently independent of the more heat which they at all times require. They receive a check very much greater than species such as *Cattleyas*, *Oncidiums*, *Epidendrums*, and *Odontoglossums*, which possess an ability to stand a lower temperature with a drier atmosphere. I am led to make these remarks through frequently seeing *Acerides*, *Vandas*, and even *Phalenopsis* and *Saccolabiums*, placed when in flower in conservatories under such conditions. They may not sustain much harm in summer, but too much air and too dry an atmosphere not only completely stop active root development, but has a most injurious effect upon the older leaves, which soon begin to shrink, and, though the mischief may not be at once perceptible, generally ends in some turning yellow and prematurely falling off when the plants are returned to their growing quarters. Valuable Orchids should never be so employed, however desirable it may be to place them where they may be most conveniently seen. I have more than once met with a way of obviating this difficulty. It was having in a conservatory attached to a drawing-room, immediately opposite the glass doors of the latter, a movable structure in the form of a Fern case. It was 6 ft. in height, some 8 ft. or 9 ft. in length, and proportionally less in width. It was fitted up with dwarf Ferns and Lycopods in the bottom, and a few hanging baskets of Orchids suspended from the top; to this only just enough air was given to keep the flowers from spotting, and as much moisture was present as kept the plants from suffering through the atmosphere being too dry, and, except during the coldest time of the year, Orchids when in flower could thus arranged be seen with comfort, and that without any material check to the plants. *Cattleyas*, *Lælias*, *Dendrobies*, and many others requiring a moderate temperature could through the spring and summer months be allowed to stand there for the full length of time during which their flowers lasted without sustaining the slightest harm.

General Treatment.—In the different houses devoted to plants requiring different temperatures the growth of many should now be in full progress. Some species, especially *Phalenopsis*, when strong and vigorous, are so disposed to keep on blooming, that those who have newly commenced their cultivation frequently feel disinclined to curtail their flowering, and the result is that injury is often done to the plants through not giving them sufficient time wherein to make new growth, or, through the period when such growth is made being deferred till late in the season, when there is insufficient daylight to solidify the growth. For this purpose I should recommend flower-stems not being allowed to remain on the plants too long during the summer months, but to cut them away, which will have the effect of inducing the plants to make growth. This, as a matter of course, does not apply to the species *P. Luddemanniana*, which regularly produces young plants from the joints of the flower-spikes, neither does it refer to strong examples of other kinds where there may be a disposition to get them to form young plants from the lower joints towards the base of the bloom-stem, which they some times do when the leading portion is cut away. These, as well as *Vandas*, *Saccolabiums*, *Acerides*, and other heat-requiring species that have done flowering, should now be afforded a brisk temperature with no stint of air during the middle of the day, to dry and sweeten the atmosphere, charging it well with moisture for a time when the house is closed, avoiding too much heat in the night, keeping the plants well up to the glass, using no thicker blinds than are absolutely necessary to preserve the plants from injury, and making a point never to have them down unless there is sufficient sun to make it necessary.

Intermediate Heat-requiring Plants, or such as are often described as Mexican house subjects (a very bad term, considering that the temperature which plants from that country need has a wide range), should also be encouraged to make stout, well matured, but not hurried growth. The majority of *Cattleyas* and *Lælias* are much more impatient of water at the roots than the generality of other Orchids; they are unable to preserve their roots in a healthy condition if the material in which they are placed be kept nearly so wet as many other species from both the Eastern and Western Hemispheres absolutely require. Through an impression often prevailing amongst the inexperienced, that Orchids collectively when growing need to be kept wet, we frequently see *Cattleyas* and *Lælias* completely ruined through their roots rotting in quantity, and leaving the plants, so that they could hardly stand in the pots without being supported. I am now alluding to plants that are grown in pots in the usual material, and not to a few individual species that succeed best on blocks, or such as have not been very

long imported, and are being kept for a year or two until they get established on blocks suspended, with little moisture-holding matter about them; in the case of such as these it will be obvious that water must be given much oftener than when the roots are enveloped in a considerable body of moisture-holding material. Neither do the plants in this department require so much atmospheric moisture as the East Indian kinds; collectively, they will bear more air, and most of them will do with less shading.

Cool Orchids.—For the next two months or so the advantages of having a house less fully exposed to the direct action of the sun than when facing the south, or a span-roofed erection standing in the usual position, will be apparent, as most of the plants thrive better with less heat than is all but unavoidably present in houses thus under the influence of the sun, on which latter it will frequently be requisite to use blinds somewhat thicker than would be otherwise advisable, but where this becomes a necessity they must never be drawn down when they can be dispensed with. Such species as *Masdevallias* will now require a maximum of water, whilst *Odontoglossums* and allied species will need the material in which their roots are placed kept fairly moist, yet it should not be in that saturated state in which it is sometimes met. I have seen these plants, although making very large pseudo-bulbs and correspondingly ample foliage, with the latter so affected with spot from the over-moist condition of the roots, and stagnant atmosphere through insufficient air being given, that they became badly diseased. The plants here will be better for air, more or less, being admitted to the house night and day.—T. BAINES.

Flower Garden.

Auriculas.—Reference was made a fortnight ago to the length of time during which Auriculas had continued in flower this season; we are now in the last days of May, and still handfuls of Alpines may be gathered out-of-doors; and, unless the weather be very hot, we may do so up till midsummer. In all my experience I have never seen them so long in bloom. I receive letters from many quarters asking for information as to the treatment which the various sections require. Every week something has been written about them, and by referring to back numbers of THE GARDEN, the necessary information for each week will be found. There are numbers of seedling raisers who are also in want of information as to the best varieties from which to save seed. It is now too late to save seeds, but those who have any should sow it at once, and thus a season may be gained. Sow it in pots or pans, and in either case drain well, placing some Moss or fibre over the drainage, to prevent the compost from mixing with it. This is quite necessary, as the seeds will not all vegetate for a whole year. The soil should consist of sandy loam and leaf-mould, with sand added if necessary. Rake the compost quite level on the surface, and sow thinly, just covering the seeds with fine soil. The pots should be plunged in a very gentle bottom-heat and be covered with a Cucumber frame or hand-lift. With the warmer weather which we are now experiencing, considerable attention must be paid to watering and keeping green fly in check, for if it increases it will seriously cripple the plants.

Carnations and Picotees.—Plants of these in pots are now all out in the open air, and, for the present, they require no more attention than seeing that they are freely supplied with water at the roots, that is, those plants that show by strong growth that there is also a corresponding root-action. A few varieties make but little growth, and, unless water be very judiciously supplied to them, they will speedily cease to exist. If the weather be very hot, let the plants be syringed freely at 5 p.m. Out-of-doors but little growth has been made so far, even in the most favoured districts as far south as London. From Bradford, and even in the south of Yorkshire, I hear that Carnations and Picotees have made no signs of "spindling," that is, throwing up their flower-stems. The surface of the beds should now be stirred, and a little fresh dressing applied; equal parts of loam and rotten manure answer well for this purpose.

Dahlias.—We shall not plant these out this year until the middle of June; the weather is fine at present, but it is impossible to say how long it may last. It is better to shift the plants into larger pots than to risk their being injured by cold winds, which check their growth and very materially retard the blooming, even if the flowers are not much injured thereby. When it is necessary to keep such plants for a long time in pots, they require all the more care as regards watering and seeing that they are freely exposed to air and light, and that there is sufficient space between the plants.

Pansies.—Those in beds are now flowering freely, and, as we expected, are making good growth. They are also strong and healthy. Last year we had a bed about 60 ft. long planted with seedlings of a good strain. That bed was a mass of bloom from May until the end of autumn, and was admired by all who saw it, some

going so far as to say that it was the best feature in the garden. The named varieties are cheap enough, and they grow as freely as seedlings. Plants in pots are more beautiful still, as regards the individual flowers, inasmuch as they can be protected from dashing rains; they require a good supply of water when the pots are full of roots.

Phloxes.—Amongst all tall growing hardy herbaceous plants, none are so effective as decorative objects in pots as these. They now require a good deal of attention. See that the stems are secured to sticks, and if the pots are well filled with roots, some rich dressing must be placed on the surface of the soil. Give plenty of water, never allowing the pots to become quite dry. I like to fully expose the plants to the sun, and if the pots are plunged in Cocoa-nut fibre refuse, or some similar material, less water will be required.

Pentstemons, Pyrethrums, Aquilegias, and several other hardy herbaceous plants do remarkably well in pots, and are all useful when in flower as decorative plants for the greenhouse. The treatment which they require is much the same as that described above for Phloxes.

Polyanthuses.—Those who have their plants still in pots would do well to place them out of doors in the open border. Turn them carefully out of their pots, and plant them without breaking the ball of earth. Ours are already well established, and are making an excellent growth, showing that they have laid hold of the rich new loam provided for them. Examine the leaves, and if they are infested with red spider, this pest must be destroyed, or else it will ruin the plants. I wash the leaves with soapy water. Green fly is also fond of the Polyanthus, and must be removed in the same way.—J. DOUGLAS.

Indoor Fruit Department.

Strawberries.—The last batches of these are now opening their blossoms, and as there is now no danger of their not setting, the weakest flowers may be picked off at once, leaving from eight to twelve of the best on each plant according to its strength. As soon as set they may at this season be given manure water daily, and on no account should they ever be allowed to get dry; such a check would render them an easy prey to red spider. Instead of saucers or turves on the shelves for the plants to root into, we have this year adopted the system long practised by some of using a second pot half filled with loam and droppings, and have reason to be more than satisfied with the result, never having had so good a supply of fruit before, not to mention the lessened labour as regards watering, and the convenience which the system affords for moving the plants from one house to another, as such has often to be done where there are not proper pits or houses for the purpose of Strawberry forcing. If the earliest forced plants have been carefully inured in cold pits to bear exposure, they may now be planted out for the purpose of producing early runners for next season's forcing.

Figs.—Established trees of these that are swelling off fruit require to be freely supplied with manure water, which may be continued till the first symptoms of ripening are observed, as also may syringing overhead and abundant air moisture. The border should be dressed 3 in. or 4 in. in thickness with half-rotted manure, which will not only benefit the roots, but will supply a valuable and necessary element to the air of the house. Let all fruit be exposed to light as much as possible, or both colour and flavour will be deficient. The tips of the shoots must be persistently pressed or pinched out, and leading shoots should be tied in, care being taken not to overcrowd. Any surplus second crop fruit may be rubbed off at once. Trees in pots from which the fruit has been gathered, after having been re-surfaced with rich compost, should be plunged in leaves to economise watering, and should be well washed with the syringe or garden engine night and morning. A night temperature of about 65° and 70° by day, with an increase by means of sun-heat, will soon tend to the production of a good second crop.

Peaches and Nectarines.—Without abundant sunshine fruit of these will neither colour well nor be very palatable, and therefore the change to brighter weather has been in every way most beneficial, more especially to fruit ripening, as that in all first early houses will now be doing. Although it is said that a Peach is not ripe till it falls from the tree, it is not wise to allow any to do so; on the contrary, examine them daily, gathering only those that part from the stalk with the slightest pull; they will then pack and travel safely, or keep in the fruit-room longer than they otherwise would do, and the flavour will be brisker than if the fruits were allowed to hang till they were over-ripe. As soon as the fruit is gathered, well wash the trees, thin out all new growths that are not required for next year's fruiting and tie in the others at such distances apart as will allow light and air to have full play on them. The borders should be well supplied with water and the trees be as regularly syringed as during the earlier stages of growth, in order to preserve the foliage good to the last, and then a good crop of fruit for another

year will be ensured. Succession-houses, in which heavy crops of fruit are swelling, should be afforded liberal supplies of tepid manure-water, and every leaf or shoot that overlaps the fruit should either be tied aside or taken off, and all lateral and sub-lateral growths should now be stopped by pinching out their points. In late houses tie down the shoots, remove surplus fruit before stoning, and syringe the trees twice daily.

Vines.—The improved state of the weather has already had a marvellous effect on Vines, more growth having been made during the last six days than in the previous eighteen, a circumstance which renders it difficult to keep pace with their requirements, as to thinning, stopping, and tying; such work, however, should never be delayed. The thinning of late Grapes should not be deferred a moment after they are ready, as growth goes on so rapidly that they soon get too large to admit of expeditious or neat thinning. The lateral growths on Lady Downes are now produced so rapidly, that unless repressed by stopping once a week they become a complete thicket, and when cut off a check to the Vines must necessarily be the result, and as a matter of course the crop is more or less injured. Houses in which the Grapes are commencing their second swelling should be shut up very early with an atmosphere well charged with moisture, and if the borders are inside well soak them with manure-water, and as this should be the last application of manure, it may be applied rather stronger than heretofore. Houses containing ripe fruit should be kept as cool as possible compatible with the preservation and health of the foliage. All lateral growth should be persistently stopped, but the leading shoot on each Vine should be allowed to ramble at will.—W. W.

Kitchen Garden.

Now that warmer weather has set in, vegetation is advancing rapidly, and the most persistent energy will now have to be exercised, in order to keep ahead of the work requiring to be done. Sowing seeds too thickly is one of the commonest errors in gardening, and if the result was only the waste of seed, that would not be of much importance; but when seedlings are neglected to be thinned till they have injuriously affected each other, and when the removal of the surplus plants destroys half the roots of the others, it will be seen how necessary it is to keep in advance of all such work. Parsnips, Early Carrots, Turnips, Leeks, and Onions are some of the seedlings that now need thinning, after which, deeply stir the soil between the rows, to induce a quicker and more vigorous growth. Peas suffer from over-seeding as much as anything with which I am acquainted. When the haulms are 2 in. or 3 in. apart they bear pods to the very bottom, which obviously would not be the case were they clustered together. Earth up and stake such as need support, and sow for succession such kinds as British Queen, Veitch's Perfection, and Champion of England. If sown in shallow trenches waterings and mulchings (both requisite in warm dry weather) will be the more effectual. The principal crop of Runner Beans should now be sown; 6 in. apart in the row will be quite near enough for these, and if the points be pinched out when 2 ft. high, that will ensure the production of pods from the very bottom of the haulm. Earth up Potatoes. If high culture be aimed at, strew between the rows guano or soot; stir deeply with a fork, and, after a good rain, earth up. The haulm should be thinned out to single or, at most, double shoots, and then, though the tubers may not be quite so numerous, they will be finer and of a more equable size. Top Broad Beans, in order to induce earlier formation of pods and to prevent an attack of black aphs, which invariably take possession of the tops of these whenever the season is favourable to their development. Unless Broad Beans be in special request, no more should be sown, as at the time when they would be ready there will be abundance of better vegetables. As ground becomes vacant, prepare and recrop it with Coleworts, Cauliflowers, Early Broccoli, Brussels Sprouts, and Savoys; the two latter will stand the severest winter, and should therefore be planted in quantity. Early Broccoli and Cauliflowers continue in use a limited time only, so these should be planted successionaly, and only in such numbers as will meet the demand. Globe Artichokes that have been raised from seed and grown on in frames may now be planted out in deeply enriched ground, and if the season be favourable, and they are not allowed to suffer from want of water, some few heads may be had in the autumn. Established plantations of Horse-radish, Seakale, and Rhubarb that are throwing up flower-stems should have them cut off and the ground receive its summer mulching of manure. Weeds may be kept down on Asparagus plots, and at the same time the roots benefited by an occasional light sprinkling of salt. Sow Lettuce where it is to stand, and thin out the plants to 9 in. apart. Tomatoes, ridge Cucumbers, and plants of similar hardiness may now be planted. During favourable weather keep the hoes going, in order to keep down weeds, which, now that rain has come, will grow apace.—W. W.

AMERICAN NOTES.

The Dewberry.—General Noble, of Bridgeport, asks, in the "Gardeners' Monthly," why so little attention is paid to the Dewberry. He speaks of the delicious Dewberries, or trailing Blackberries of Virginia, some of which he says are 1½ in. long.

Wistaria japonica.—Besides the purplish-blue variety, spoken of in Parson's Catalogue, we notice pink and white now growing in California. The racemes did not attain a length of much more than 1 ft., but they had not had time to fully recover from their journey from Japan. The fragrance is delicious, and attracts insects to an annoying extent.

Blue Gums in St. Joaquin County.—The Eucalyptus is beginning to be largely planted in this county along roadsides and in the form of groves. In gardens and city lots it is not here, any more than elsewhere, a satisfactory tree. We have also noticed that the trees were greatly affected by the frosts of last winter, in some cases hardly recovering.

Drying Raspberries.—A correspondent of the "New York Tribune" says there is no kind of dried fruit in such brisk demand in the market as Raspberries, and that it is quite as profitable to dry them as to sell them fresh. 100 quarts will make 30 lb., which, at 30 cents per lb., gives 9 cents per quart for the fresh fruit, less half a cent, the cost of drying. The Black Cap is here alluded to, which he states is the most hardy, reliable, and easily-grown of small fruits.

A Dwarf Cypress.—We lately observed, at the nurseries of Mr. West, Stockton, the most unique little tree imaginable. It is an accidental seedling from Cupressus macrocarpa, and a more compact, globular, neat-leaved dwarf Conifer we never saw. We have forgotten exactly the number of years which have passed over its head, and we fail to remember the exact number of inches it was in height—little enough certainly—but we are quite sure that it is worth propagating, and sending out as a good dwarf of California parentage.

Rose Hedges.—In the grounds of the State Insane Asylum in Stockton we saw some fine effects produced by various hedge plants. One of those hedges was formed of perpetual Roses trimmed close to a height of 2 ft., and, being full of leaves, buds, and blossoms in a perfect mass, is an entire success as a hedge. We should suggest that the alternating of red, white, and yellow, or the planting of opposite sides of a walk with different colours, would give a pleasing variety.

The Stockton Insecticide.—Mr. Milco, of Stockton, has, for some years past, been investigating the properties of Pyrethrum carneum, a plant largely used in Dalmatia for the manufacture of various insect preparations. Believing that there was room for the business, he introduced the plant some years ago, and, after many trials, and not a few tribulations, has, beyond a doubt, put his article on a sound financial basis. The preparation, which is made from the flowers, is called by a Dalmatian name, "Buhach" (pronounced Boohatch), and this title has been patented by Mr. Milco as a trade mark. The quality of this insecticide, made from fresh flowers, appears to be superior to that of any now in the market from foreign sources. Professor Hilgard has brought various comparative tests to bear upon it, and gives it his endorsement.

In the "Rural New Yorker" we find a plate and description of a New Quince, The Champion. This variety originated on the grounds of Mr. George Perry, Fairfield, Conn. It is of large size, and resembles in shape a Duchesse Pear. Its chief merit seems to be that it comes into bearing very early, and is very prolific.—California Horticulturist.

Early versus Late-flowering Magnolias.—Most people will acknowledge, if they will be frank in the matter, that they object to Chinese Magnolias, so-called on account of their peculiarity of blooming before the development of the leaves. We miss the foliage which attains such beauty later, and while we would not sacrifice the wonderful beauty of the flowers in early spring, we cannot help wishing that fine foliage might accompany such fine flowers. It is probably for this reason that the late-flowering Magnolias are so popular, notwithstanding the comparative inferiority of their bloom. That of *M. cordata* is yellow, of medium size, attractive, but not extraordinary in any way. The same may be said of *M. glauca*, except, perhaps, that it is sweet-scented, while the flower of *M. macrophylla* is noteworthy only for its large size. What we want is an attractive, sweet-scented, good-sized Magnolia flower that develops at the same time as the leaves. *M. hypoleuca* is such a species, as well as one other variety not yet named. Yet so few of even the first of these Magnolias have been offered to the trade that it is not strange that they are overlooked.

Abutilon insigne.—This is a fine variety of the *Abutilon* family, which, though old, is still quite rare, and deserves to be more generally grown. In a November number of *THE GARDEN* it is figured under the name of *Abutilon igneum*, but later on in December it is spoken of, in the same paper, under its proper name of *A. insigne*. As long ago as 1860 we had fine, large plants of this variety, which we had grown purposely for winter blooming, producing, as it does, large, pendulous clusters of velvety, crimson flowers, veined with dark maroon, in great profusion all winter long. Unlike any other variety, this throws its flowers well out from the foliage, each terminal shoot being literally loaded with perfect bells. The leaves are of a rich dark green, of thick texture, and prominently net-veined on the under side. This variety is quite distinct in leaf and flower from any other, and deserves to be in every good collection.—C. H. HOVEY.

The Best Time to Transplant Magnolias.—There exists a common impression even amongst experts that *Magnolias* should be transplanted as early as possible in the spring; experience, however, teaches just the contrary. In fact, a *Magnolia* should not be transplanted until the leaves begin to show signs of pushing, which, in the case of Chinese *Magnolias*, is while the flower is in full bloom. There is a sluggishness in the spongy texture of the *Magnolia* roots which, like that of the roots of evergreens, needs warning up before transplanting can be attempted with the greatest certainty of success.

MR. THOMAS HOGG in the "Gardeners' Monthly" explains to Professor Sargent the difference between "introduced" and "first introduced," and calls attention to the fact that *Cercidiphyllum* is spelt *Cercidiphylum* in Miguel's *Flora Japonica*.—"Moore's Rural."

Trees and Shrubs for Lawns.—In selecting these the tendency to follow mere fancies, or to use only particular and favourite plants, must be kept in strict abeyance. Many and various plants should be employed intelligently. Hardy deciduous trees, shrubs, evergreens, herbaceous and bedding plants, in short, everything that conduces to the beauty of the lawn, must be united into one harmonious whole. Doubtless there are occasions when a mass of colour, obtained by using many plants of one kind, is desirable, but generally a variety of plants and methods of combination is more desirable. The eye thus never becomes satiated, and is ever renewing its pleasure. But what is the actual condition of lawn-planting as practised to-day in the case of myriads of small places throughout the country—places, moreover, that belong to intelligent people? The entire collection consists frequently of a few fruit trees in the background, an Elm, a Norway Spruce, an Arbor-vitæ hedge, with a bed of the glowing *Coleus*. All these plants, be it noticed, are of the most pronounced and coarsest type. They may be and are valuable in suitable positions or in other combinations, but are decidedly ill-fitted for the interior of a small place, both from the character of their beauty and their habit of excessive growth. We intend no disrespect for either of these varieties, many of their qualities being, in their own way, most admirable; but we do say that if other and good selections were made after studying parks or nurseries, fewer poor lawns would exist. Landscape gardening, or lawn-planting, seems very difficult to some, and is practically considered a myth by others. To one class we can only say, practise it yourself and difficulties will soon disappear; it has no arcana into which you cannot pierce. To the other we answer, lawn-planting exists, and has its æsthetic laws, just as taste in general has definite laws.—S. PARSONS, in "Scribner."

Effects of the Frost in Devon.—Plants that have stood out-of-doors for years here, such as *Veronicas*, *Euonymuses*, large *Fuchsias*, &c., in good situations, have this winter been killed to the ground. *Laurostinus* are also much injured; young stock of them in the nursery have not had a green leaf left on them. Myrtles on the house walls too are quite bare, but are now breaking freely. *Rhododendron Dalhousianum* is much injured, and looks very badly while *R. cinnabarinum*, a coloured plate of which appeared in *THE GARDEN* a few months ago, is quite uninjured, and is again in full bloom; *R. Thomsoni* and *R. campylocarpum* are also unharmed. Our large plants of *Dracena australis*, from 14 ft. to 15 ft. high, with clean stems from 9 ft. to 10 ft. in height, are not even browned; on the contrary, they are growing vigorously, and in the case of one of them several growths are bursting from the main stem; these unprotected were killed to the ground in 1866, and my neighbours have had theirs killed this year. I saved mine by well protecting their stems with straw bands, tightly and neatly bound round from the ground upwards as far as possible, and then I thatched with straight Wheat straw, in order to keep them quite dry, leaving all the dead under leaves on to protect the top of the straw. I treated two plants of *Dicksonia antarctica* in the same

way; their leaves were quite killed, but the larger of the two is unfolding healthy fronds, but the other, a much smaller plant, I fear will not start. They were planted within a few feet of each other. Both the *Ferns* and *Dracena* will repay the little trouble which it takes to protect them, as these and *Palms* give a place quite a tropical character. I protected *Chamaropsis Fortunei* in the same way, but probably it would have stood uninjured without that attention. One of the most beautiful shrubs now in flower here is *Pyrus* (*Malus*) *floribunda*, every plant of which in all sorts of places is loaded with blossom, which in the bud state is most beautiful. This *Pyrus* grows freely, and should be freely planted along with the best *Thorns* for ornamental effect. No Hawthorn here is yet in flower, a circumstance which shows the lateness of the season, as Hawthorns are generally in full bloom here the second week in May.—JOHN GARLAND, Killerton, Exeter.

THE FRUIT GARDEN.

GRAPES FROM EYES RAISED THE SAME YEAR.

THAT Vines can be induced to fruit the same year in which they are raised from eyes has often been proved, and the fact that they will do so is instructive, inasmuch as it shows the wonderful inclination which the Vine has to produce fruit, and its disposition to conform to varied treatment. But beyond this, as far as either my own experience goes and that of others who have tried the plan, it has nothing to recommend it, for the weight of fruit obtainable is too small compared with the length of time during which the Vines require room and attention. Take, for instance, a case where new houses have been erected, with no old home-grown Vines at hand to fill them. If the grower were to raise his own from eyes and have many more than he required, and if he were to fruit a portion in the way described, he would require a separate house or pit for the work, as it scarcely need be pointed out that the permanent Vines would want to have their growth matured and their leaves off by the time those in fruit had ripened their crop. If, instead of this, he were to buy fruiting Vines, so as to have double the number required for permanently occupying the space and fruit the super-numeraries, the extra weight of fruit obtainable in this way over fruiting from the current year's raised Vines would more than compensate for the cost. "J. S. W." is wrong in instancing what Mr. Hardie did, as regards ripening a crop before the close of the year in which the houses were completed and the Vines planted in April, because the Vines, instead of being raised that year from eyes, were, I believe, very strong ones of the previous year's growth. I have before me the account given at the time, which says the Vines (*Muscats*) were furnished by Messrs. James Dickson & Sons, Chester; they were cut down to within 3 ft. of the ground, and planted in April; they quickly reached the top of the house strong and healthy, some of them nearly 1 in. in diameter; the tops were then cut off, and all the laterals taken out; they then started again, and were allowed to carry an average of nine bunches each. This was thought at the time to be a great feat, but, without the slightest disposition to disparage, I fancy most Grape growers failed to see it, or to approve of young permanent Vines being so treated. Premature cropping is always condemned, but here it was carried out in a most exhausting form. Most likely this was one of the numerous instances that occur in which present exigencies demanded more consideration than the future; nevertheless, an equal result might have been obtained by other means. So far, however, as growing Grapes from Vines of the current year's raising is concerned, I cannot look upon it as anything more than a cultural curiosity, for the simple reason that a better return may be obtained in other ways.

T. BAINES.

—I remember well the circumstance referred to by "J. S. W." (p. 403) and also the interest created by Dr. Lindley's congratulatory remarks upon the subject. I also recollect a visit which I paid, in company with others, to the gardens in question, situated at Wells, in Norfolk, for the purpose of seeing these Vines in the following spring. Mr. Hardie had then left the place, and was, I believe, on his way to Egypt. That was, I think, about eighteen or nineteen years ago. The Vines were planted along the front of the house—a lean-to— and trained up the rafters in the way usually followed in the case of permanent Vines, and the canes were of about average size and strength. The object had been to break the upper half of the rods, fruit them, and then prune the fruiting ends away, and break the lower portion for the following year. But the Vines had evidently not taken kindly to the treatment; for, although the first part of the system was carried out, the second part, at the time of our visit, looked very much like a failure. The truth is, we cannot eat our cake and keep it too. The conclusion to which we came, after comparing notes, was that it was not a system likely to become general,

and, in fact, there was nothing heard of the Vines at Wells afterwards; but if I understand "J. S. W.'s" previous communications, his remarks have applied more to pot culture than to permanent Vines, and it is obvious that the two are not on the same level. With high culture, it may be applied to the former with a fair amount of success, but high pressure work of this kind applied to Vines must destroy their permanent character.

E. HOBDAY.

PINCHING ORCHARD HOUSE TREES.

SOME of your readers who are amateur cultivators of orchard house trees may not be quite certain as to the proper lengths to which the shoots should be pinched. The accompanying illustration represents a sketch of a shoot from one of my forced trees—a Nectarine. The first pruning, I find from experience, should be at the fifth leaf, as a general rule; the sketch will, I think, sufficiently explain my meaning; it is intended as a guide for the practice of pot culture. My forcing house of trees in pots is now full of fruit well advanced. The weather which we have experienced during the past winter and spring, will, I hope, have convinced the most incredulous that, although Peach growing out-of-doors may have been carried to a pitch of perfection by our ancestors, it is a painful task to their posterity. Happily, the cold storms and nipping frosts are harmless to

Shoot of Nectarine pinched for the first time.

trees under glass, a luxury which we can enjoy. My trees both on trellises and in pots are crowded with fruit, and one house, twenty-five years old, is as productive as ever it was.

Sawbridgeworth.

T. FRANCIS RIVERS.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Artificial Heat for Vine Borders.—"J. S. W." objects (p. 358) to leaves as proof that good Grapes may be grown without the aid of fermenting materials on Vine borders, and yet he knows as well, or better than most people, that the size and condition of the foliage is the surest index as to the state of the Vines, which any one could furnish, and ought to be far more satisfactory than a bunch of unripe Grapes. If I had sent unripe fruit, "J. S. W." might have raised an objection to that; but if he requires additional proof of what I stated, I shall have much pleasure in bringing that forward later in the season. I may state that the Vines from which the leaves in question were cut are, and have always been, in an outside border, and are now about twenty years old. At one time I used to apply heat to the border, but I have long since given it up, as I was of opinion then, as I am now, that it is productive of more harm than good.—S. D.

Inference to the remarks on this subject, permit me to suggest that those of your correspondents who give us their opinions should state: 1. How many years their Vines have been forced. 2. At what time the fruit is usually ripe. 3. The nature of the soil, whether light or heavy. For my own part, having had to supply Grapes in May during the last twelve years, I have found a moderate covering of warm manure and leaves applied to the roots very bene-

ficial, but I should be glad to dispense with the labour entailed thereby could I only get satisfactory evidence of its not being required. I would venture to suggest, however, that Vines that have not been forced for say three years, so as to have ripe Grapes in May, should not by any means be allowed as evidence in the matter, as Grapes ripe after that month cannot be called early in the true sense of the term. As to "S. D.'s" remarks (p. 373) on the Vines which produced the foliage which he sent for inspection, I do not see what bearing they have on the subject further than to show that his Vines produce fine foliage, which I admit is in some cases, not in all, associated with good fruit. However, to put the matter to a practical test, permit me to ask "S. D." to send up to THE GARDEN Office, during the month of June, two average bunches of Grapes from his Vines, and I will undertake to do the same from Vines that have been treated with artificial heat at the roots. I may mention, too, that the Vines from which my fruit will be cut have produced ripe Grapes in June during the last three years, and that they have been heavily cropped, a fact that can be attested by several of your readers.—H. J. C., *Grimston*.

For nine long years have I always had manure and leaves to the depth of from 2½ ft. to 3 ft. thick on the border of my second early house, and also on the border of the Muscat house, and I kept them regularly turned to keep all sweet, and I have always been rewarded with good crops of fairly good Grapes; still, the bunches never came up to my standard, being loose and too long. Some, I know, will say, Oh, the wood was not ripe; but it was ripe and solid. I therefore this season altered my usual course, and merely protected the border with dry straw, and the result is a magnificent show of close, compact, but not little bunches now, May 9, thinned. I therefore feel certain that warm roots have a tendency to make bunches long and straggling, and I shall never again warm a Vine border, so much satisfied am I with the result in an opposite direction.—R. GILBERT, *Burghley*.

New Plan of Filling a House with Vines.—Mr. Baines has, he tells us, tried this plan more than once and failed, but that is no reason why others should fail also. If he will honour me with a call now, I will give him a chance of picking out this Vine from the others, if he can, by any excess of vigour at the top, and weakness at the bottom, or elsewhere, which he says are the results of the practice. Not only is this Vine equal to the others in the house as regards equalisation of vigour among the branches, and their regular distribution from top to bottom, but it is better than some of them. I will also show him a number of other Vines of different varieties that have been treated in the same way, but which have not such a length of rod, and to which the same remarks apply; and in the case of all the experiment has been going on for nine or ten years, a longer period, perhaps, than Mr. Baines' experiments extended over. As to the plan of cutting down Vines to the bottom wire the first year, and leaving a few feet of wood every year afterwards, I said it was the usual plan, and so it is, but I did not say it was the best plan under all circumstances, or recommended it. It may be slow for Mr. Baines, but if he will turn to my articles on the Vine in the early numbers of THE GARDEN he will there find as expeditious a method of raising and fruiting Vines recommended as he ever probably practised. It is a noticeable feature of Mr. Baines' Grape-growing experiments that he has more to say about his neighbours' than his own success, though it does not seem to be possible to suggest anything in connection with the subject that he has not tried and settled beyond all question, even so long ago that he only reveals his secrets when he finds they are no longer worth keeping. Will Mr. Baines state any one case, and where he has seen the system tried, and give particulars of the experiment?—J. SIMPSON.

The Apple Blossom.—In a large orchard in North Hants I observed the other day at least one-half of the Apple bloom as good as killed by frost ere it had expanded its petals; the style and the fruit germ were as black as one's hat. This orchard was situated in a dry, airy position, and considerably elevated. It may, however, turn out that such mischief is but local, as on returning home I examined the trees here, and found no trace of damage. It is worthy of note that Pear blossom is, within a short distance of the orchard in question, marvellously abundant and quite unharmed; indeed, whilst the Apple bloom is comparatively abundant, the Pear bloom is unusually so, and heavy crops may be looked for. In the metropolitan market gardens Black Currants are spoken of as being thin, but most other fruits are promising, although more than that it is not yet safe to predict.—A. D.

Vicomtesse Hericart de Thury Strawberry.—After seeing the grand examples of this Strawberry produced at Heckfield, where it is chiefly grown for forcing purposes, I am surprised to find that some still speak unfavourably of it. There it produces as fine fruit as President and of better flavour, and the crop is half as large again as that of President. Buffa Corn manure is incorporated

with the soil in which the Strawberries are grown, and another element of success is the securing of good early runners. In winter the plants are stored so that the balls do not get dry, and therefore they lose none of their roots, which they do in the dry-as-dust plan of wintering. The pots are plunged during winter in ashes or leaves, thus giving the roots some protection, but in other respects they are allowed to take their chance.—A. D.

NOTES OF THE WEEK.

Saxifraga Wallacei.—This handsome Saxifrage, to which we had occasion to refer last season when in flower, is now very attractive in several collections, notably those at Kew and in Messrs. Osborn & Sons' nursery at Fulham. It is apparently unknown in herbaria; hence its provisional name has not been authenticated nor its affinities explained, but it is, for horticultural purposes, very distinct from any other cultivated kind. It is in the way of the fine Algerian *S. Maweana*, and in our opinion, is much superior to it, as it is far more robust and less difficult to manage, besides being earlier, freer as regards flowering, and very easily propagated. In one point it differs from *S. Maweana*, viz., in not developing the small, round buds during the summer, which is such a marked characteristic of the latter kind, and which is very detrimental to it under culture, as it often gets thrown away as dead by the uninitiated.—W. G.

Cattleya Reineckiana.—We last week saw a flower of this extremely rare and charming Cattleya, from Sir Trevor Lawrence's collection, at Burford Lodge, Dorking. It belongs to the Mossie section. The individual bloom measured $\frac{7}{8}$ in. across; the sepals and petals are of great substance, and of the purest white. The higher part of the labellum at the point where it begins to unfold is suffused with lemon, below which is a large blotch of vivid purple, the margin being beautifully fringed. A few examples of the plant were introduced many years ago, but in such limited numbers, that comparatively few Orchid growers have seen it in bloom; and it was at one time supposed to be lost. We know of no species in this showy family that surpasses it in beauty.—P. G.

Petrea volubilis.—One of the greatest ornaments in the large conservatory in the Royal Botanic Gardens, Regent's Park, is this beautiful and now little-known climber, which is an old introduction from Vera Cruz. It ranks, without doubt, amongst the finest stove climbers which we possess, as it is easily grown and scarcely ever fails to produce a crop of delicate mauve, star-like blossoms, which hang in long racemes in graceful profusion, and continue in beauty for a considerable time. A coloured illustration of it appeared in *THE GARDEN*, Vol. XII., Plate LXXXII.—W.

Muscari paradoxum.—In the note given in our last issue (p. 424) we mentioned that the *Muscari* which we received from Colchester under this name was not the true plant, according to Mr. Baker. We are now asked to correct this statement, which is described as an error. This, however, we cannot do, as the plant sent to us is certainly not identical with *Muscari paradoxum* contributed to the Kew collection by Dr. Regel, which flowered for the first time last year, and which was authenticated at the time by Mr. Baker. The true plant is so well marked and distinct from any other cultivated species that it may be recognised at a glance; indeed, if we mistake not, it is still doubtful as to whether it is not generically distinct from the other species of *Muscari*. The specimen from Colchester is apparently identical with *M. compactum* of Baker, though the material is not at hand to enable us to settle the point; however, the same species was noticed a day or two since in the Kew collection flowering by the side of the true plant, having been recently contributed from a well-known nursery, and not yet revised. The following short description of the true *M. paradoxum* will suffice to distinguish it from others: Bulb larger than that of other kinds; leaves three, about 9 in. long, $\frac{1}{2}$ in. to $\frac{3}{4}$ in. wide, quite erect, deeply channelled, and bright green; flower-stem 6 in. to 9 in. long, terminated by a dense raceme of small, oblong flowers, blue-black in colour, and exhaling a faint scent. It is a native of the Caucasus.—W. G.

Shrubs in Flower at Coombe Wood.—A fine feature just now in Messrs. Veitch & Son's nursery at Coombe Wood is the flowering specimens of *Magnolias* belonging to the deciduous group, especially the beautiful *M. Lenei*, of which we gave a coloured illustration in *THE GARDEN* (Vol. IX., plate XXIV.). It is perfectly hardy and flowers very freely. It is not often that we meet with any Australian *Protea* flowering in the open air in this country, but here may be seen fine examples of the pretty Rosemary-leaved *Grevillea* (*G. rosmarinifolia*) in full bloom. Its curious red flowers are borne profusely amidst the dense evergreen leaves, which are narrow and very rigid, and from 1 in. to 2 in. long. *Pyrus*

Maulei, figured in *THE GARDEN* (Vol. XIII., p. 390), is also beautifully in flower. The Coombe Wood specimens are dwarf in habit, and produce their orange-scarlet blossoms in abundance, succeeded by numerous bright orange and red fruits. *Daphne Cneorum*, though an old and well-known dwarf shrub, still ranks amongst the most beautiful of spring flowering plants. The deep rosy tint of the blossoms, the profusion with which they are produced, added to their delicious perfume, especially when planted in masses, render it a very desirable plant for every garden. With blossoms of a similar colour and equally as free flowering is the Glauco-leaved *Kalmia* (*K. glauca*), a very showy kind, well deserving of more extended culture both out-of-doors and for early forcing. *Polygala Chamæbuxus* is here quite at home and flowering profusely, though not so showy as its rose-coloured variety. The various species of *Ledum* will soon form an interesting feature, as well as the numerous masses of *Rhododendrons* which thrive so admirably at this nursery.—G.

Hardy Orchids at Kew.—In one of the open borders in the herbaceous ground the following species are now in flower, viz., *Serapias cordigera*, a beautiful South European kind, the blossoms of which have heart-shaped lips of a rich claret colour; *S. lingua* differs from this in having a tongue-shaped narrow lip, but it is similar in colour; *Ophrys Speculum* is a strikingly beautiful species, the lip of which shines like burnished steel, and is bordered with rich brown velvet; *O. araniifera* and *O. fusca* are also very singular but not prettily marked kinds; *Orchis provincialis*, with creamy-white blossoms copiously spotted with brown, is also very elegant. The various kinds of hardy *Cypripedium* are thriving vigorously, and the North American *C. pubescens* is already bearing handsome yellow-lipped blossoms.

New Masdevallia.—A *Masdevallia* of the *Chimara* group is now blooming in the York Nurseries. The flower measures 10 in. from tip to tip, ground colour very pale, nearly white, richly and heavily spotted all over with claret-purple. Each segment, especially at the margins, is shaggy, with rough coarse hairs, giving the flower a novel and extraordinary effect. The "tails" are deep purple. We understand that of this *Masdevallia* one plant only has yet been seen, and that a portion of it is to be offered for sale at Stevens' week (29th inst.). Professor Reichenbach, to whom a flower has been sent, provisionally names it *Masdevallia Backhousiana*.

A New Allium (*A. kuraataviense*).—This novelty from Turkestan is now in flower in the open borders at Kew, but it is not such a desirable plant as the figure given of it a short time since in Regel's "Gartenflora" would lead one to suppose, as the flowers are of a dull, livid purple tint, and not at all showy. It is, however, very beautiful in foliage, especially when the leaves first unfold, as they are from 2 in. to 4 in. broad, have several longitudinal ribs, and are of a deep glaucous-green colour, bordered with bright red. The whole plant does not exceed 9 in. in height.—W. G.

Alpinia nutans.—This remarkably handsome plant is now finely in flower in the Palm House, at Kew. It belongs to the now much neglected family of Scitamineæ. It is Canna-like in habit, has bold foliage and stems, from 6 ft. to 8 ft. high, terminating with drooping racemes of blossoms, which have much the appearance of those of an Orchid, being of firm waxy texture, whitish on the outside, and having a heart-shaped lip of a rich orange colour, heavily pencilled with orange-red.

New Hardy Rhododendron.—Mr. Luscombe has shown us a cut specimen of a beautiful seedling *Rhododendron*, the result of a cross, effected at Combe Royal, between *R. Fortunei* and *Thomsoni*. Its trusses of flowers, and also the individual blooms, are large and showy, the colour being a delicate rosy-pink, paler in the centre than at the edges or back of the flower. It has bloomed freely in Mr. Luscombe's garden in the open air.

Xanthoceras sorbifolia.—This lovely Chinese shrub will shortly be in flower in Messrs. Veitch & Son's nursery at Coombe Wood. An interesting fact in connection with it is that it has withstood the past winter with impunity, though quite unprotected and in rather a bleak position. It will be found well figured in *THE GARDEN* (Vol. VIII., p. 524), accompanied by an engraving of the fruit.—W.

Ochna multiflora.—We noticed a very remarkable stove shrub bearing the above name in one of the collections shown the other day at South Kensington by Mr. E. S. Williams, of Holloway, but whether it be correct with regard to its nomenclature or not we are unable at present to ascertain. The specimen in question was in a fruiting state, and the numerous clusters of pea-like fruits arranged in a circular manner on a fleshy bright red disc with the reflexed calyx segments of the same colour had a very pretty effect, especially when contrasted with the bright green foliage.—W.

GARDEN DESTROYERS.

THE LILAC MOTH.

(GRACILLARIA SYRINGELLA.)

This beautiful little insect, when in the caterpillar state, is often a great annoyance in gardens by spoiling the foliage of the Lilac bushes. The leaves, when attacked by them, wither and crumple up, which gives the bushes a most dismal appearance. The moths are very common and widely distributed; they make their first appearance in May, and lay their eggs on the young leaves of the Lilac as soon as the buds open; they may again be found in July and September, for there are three broods during the season. As soon as the eggs are hatched, the caterpillars make their way, sometimes several together, between the upper and lower skins of the leaves, and feed on the parenchyma or interior substance of the leaf,

Gracillaria syringella.

which soon withers and shrivels up. As soon as the caterpillars can obtain no more nourishment from the leaf, they reappear on the surface and move to other leaves. They then provide themselves with a shelter by rolling up a leaf, or by fastening two or three leaves together with silken threads; thus protected from the weather and many other enemies, they feed principally upon the upper surface of the leaves that surround them. They attain their full size in about a month, and then, leaving their habitations, let themselves down by threads in search of a suitable place where they can undergo their change to the chrysalis state. Having found a convenient position under a leaf, or in some crevice in the bark, they each spin a small oval cocoon round themselves, within which they become chrysalides. In this state the insects remain for ten days or a fortnight, when the moths emerge from the cocoon, and soon begin to lay their eggs, which are hatched in due course, and the second brood of caterpillars begin their work of destruction. This generation attains the perfect state in September. Again eggs are laid, but the transformations of this brood are not completed until the following spring, as the insects remain in the chrysalis state during the winter, the perfect insects appearing in May. The best way of

getting rid of this pest is to gather all the leaves which are attacked as soon as the injury is perceived, and to destroy them by burning or burying them; by this means the numbers in the following generations will be considerably diminished. The caterpillars suffer much from the attacks of ichneumons, who find them out even when they have made themselves most secure. The moths are so small, that they are very difficult to find; if in great numbers it might be worth while to shake the boughs occasionally, and capture any moths which are disturbed with an ordinary butterfly net, or they may be shaken into an open umbrella. This insect belongs to the group of moths called Tineina, which contains a large number (about 650) of British species. They are mostly very small; some, indeed, only measure 2-10ths of an inch across their wings when fully expanded. The colouring of these moths is often exceedingly brilliant, some appearing as if they were most richly gilded; their wings are all long and narrow, and are usually very deeply fringed; their antennae are long and delicate, and not toothed in any way; in some species they are very long, and are more than four times the length of the insect. The caterpillars of many species mine in the leaves of various plants; others form portable coverings of the substances on which they feed, which they carry with them. The moths whose caterpillars are the little grubs which do so much damage to furs and woollen articles belong to this family. The moths of the genus Gracillaria may generally be recognised when at rest by the very peculiar way in which they sit, with their heads very much raised. The Lilac moth measures about $\frac{1}{4}$ in. across the open wings (in the figure it is represented considerably magnified), which are very narrow in comparison with their length; the upper pair are brown, with several whitish markings and various streaks of brownish gold, and are deeply fringed; the lower wings are pale greyish-brown, with very deep fringes. The antennae are longish and very delicate. The caterpillar is about 2-10ths of an inch long, and is of a greenish-white colour with a darker head. The body is composed of twelve joints, and is furnished with seven pairs of legs; one pair on each of the first three, and on the sixth, seventh, eighth, and last joints. The cocoon is composed of whitish silk, and contains a brown chrysalis.

G. S. S.

SOCIETIES AND EXHIBITIONS.

CRYSTAL PALACE.

MAY 24.

At this the great summer exhibition held on Saturday last the principal features were some exquisite groups of Roses, a brilliant collection of Clematises from the Woking Nursery, showy groups of Azaleas, and the usual well-grown stove and greenhouse plants. Tuberos-rooted Begonias, too, were very attractive, and admirably exemplified what rapid strides have been made within the past few years in regard to the improvement of this showy class of plants. Yucca-like plants were numerous and varied, and received their full share of attention, amongst the most noteworthy being tastefully arranged mixed groups from Messrs. B. S. Williams and Messrs. John Laing & Co., and a pretty group with umbrella fountain above in terra cotta from Messrs. Dick Radcliffe & Co., to all of which extra prizes were awarded.

First-class Certificates were awarded to the following new plants—

Adiantum Williamsi (Williams).—An elegant Fern from the mountains of Peru. It grows about 9 in. high, and has spreading fronds, the pinnules of which are membranous and of a bright green colour. A decided acquisition to our lists of greenhouse Ferns.

Cupania elegantissima (Williams).—A graceful plant about $1\frac{1}{2}$ ft. high, with pinnate leaves of firm texture, resembling those of a Cycad. A useful decorative table plant.

Geonoma gracilis robusta (Williams).—As its varietal name implies, this Palm is more robust in growth than the type, and is also a graceful decorative plant of easy culture.

Croton Henryanum (Williams).—A variety of bold habit, with ovate leaves prettily mottled with green and creamy-yellow.

Sarracenia Williamsi (Williams).—An interesting hybrid partaking of the habit of *S. flava* and *S. purpurea*, with leaves from 9 in. to 12 in. high, erect, the lid of the pitcher-like leaves measuring about 3 in. across; light green in colour, veined with crimson, especially on the upper half of the leaves.

Croton Williamsi (Williams).—A handsome form of good habit and free growth, with large oblong leaves richly coloured with green and yellow, and streaked with crimson.

Begonia altheaeflora (Laing).—A beautiful double-flowered variety, with blossoms resembling those of a Hollyhock in miniature and of a red-cerise colour. A very desirable acquisition.

Begonia Maude Churchill (Laing).—A variety with richly-marked foliage, and large, roundish, orange-coloured flowers tinted on the outside. It is dwarf and very vigorous in habit.

Calceolaria Crystal Palace (Ford).—A remarkably fine variety, producing fine trusses and very large blossoms.

In addition to the foregoing, the following, which have received certificates elsewhere, and which have been previously described in our columns, also obtained first-class certificates, viz., *Comtesse H. de Choiseul* (Laing), *Marie Bonchet* (Laing), *J. H. Laing* (Laing), *Mamillaria formosa* (Boller), *M. filifera* (Boller).

Miscellaneous Plants.—A superb group of pot Roses from the Cheshunt Nurseries was a great source of attraction, and certainly the plants composing it were perfect models of cultural skill. A grand plant of Charles Lawson measured from 7 ft. to 8 ft. across, and was literally covered with deep rose blossoms of good form. *Celine Forester* was of similar dimensions, and equally well flowered. The other varieties were the blush-tinted *Souvenir d'un Ami*, *Madame de St. Joseph*, the deep, rich-coloured *Victor Verdier*, *Dr. Andry*, *Beauty of Waltham*, *Edward Morren*, and *Anna Alexieff*, all large, admirably grown, and well staged. The prizes offered in the class for eighteen only brought out one collection, and that was from the Slough Nurseries; it was arranged in two groups. The plants of which it consisted were not large, but many of them were well flowered, and deservedly much admired. The *Azaleas* formed a very prominent feature, the classes being numerous and well filled. The group of nine plants from amateurs, to which the first prize was awarded, was particularly fine, as the specimens were not only well flowered, but the flowers individually large. The other entries merited no comment, with the exception of a collection of eighteen plants from the Slough Nurseries, to which a first prize was awarded. The plants were not large in size, but the flowers were unusually large and highly coloured.

Stove and greenhouse plants were numerous, and comprised some remarkable examples of skilful culture, especially in the amateurs' class for nine, in the first prize group of which were very fine plants of the yellow-flowered *Erica Cavendishi* and *E. depressa*, profusely flowered specimens of *Acrophyllym venosum*, the showy-looking *Statice profusa*, and a huge plant of *Ixora coccinea*, covered with large clusters of orange-scarlet blossoms. The next group in point of merit were large well-flowered specimens of *Azaleas* and a superb plant of *Imantophyllum miniatum*. The exhibits in the nurserymen's class were scarcely so good as we have seen, though the nine plants from the Kingston Nurseries comprised well-grown plants, most of which we noticed last week. In the first prize collection of six from amateurs, *Erica ventricosa*, *Epacris Eclipse*, *Azalea Perryana*, and *A. Iveryana* were prominent examples of good culture. Fine foliated plants were remarkably well shown, especially those from amateurs; the nine which gained the highest award comprised *Croton interruptum*, *C. variegatum*, *C. Wiesmanni*, *Gleichenia semivestita*, *Dasyliroth glaucum*, *Areca sapida*, *Latania borbonica*, and *Zamia Lehmanni*, all plants in good condition. The best plants in the second prize lot were *Dieffenbachia Bausei*, *Anthurium crystallinum*, *Croton variegatum*, and the prettily mottled-leaved *Spathiphyllum pictum*. In an extra prize collection were *Gymnogramma gigantea* in fine condition; *Alcascia metallica*, and *Dieffenbachia picta*; the last of a size rarely seen and unusually vigorous. Heaths were badly represented in both classes, and merit no comment. *Dracenas* were shown numerous and in the form of good specimens, including besides many of the finest hybrids, the ornamental *D. Goldiana*, which makes an excellent exhibition plant.

Orchids were not numerous, but amongst them were a few excellent plants. A grand mass of *Phalenopsis grandiflora* with ten spikes of flowers was especially noteworthy; also *Vanda saravis* with eight spikes. The pretty *Dendrobium Falconeri*, well flowered, and the gorgeous *Cattleya Mendelli* were much admired.

Crotons were also numerous, but with the exception of the first prize collection they were not very remarkable. The former contained large and well-coloured plants of *C. volutum*, *Youngi*, *magesticum*, *trilobum*, *interruptum*, *multicolor*, *Cooperi*, *Hendersoni*, and *augustifolium*, of a size rarely seen at an exhibition.

Ferns were but scantily shown, there being but one entry in each class, and none of these were very noteworthy.

Begonias were shown in admirable condition and in the form of large specimens, especially the group from the Stanstead Park Nurseries, which gained the highest award. The best varieties amongst them were *Massange de Louvrex*, *Madame Oscar Lamarche*, *J. W. Farrand*, *Calyppo*, *Cleopatra*, *Baronne Hruby*, and *Thomas Bell*.

Pelargoniums were well shown, though not abundantly, those from the gardens at Redlees and the Slough Nurseries fully maintaining their supremacy.

Calceolarias were remarkably fine, and one variety in particular named *Crystal Palace*, to which a first-class certificate was awarded, was the finest that we have yet seen. Hardy flowers were, as usual, shown badly; the only collection staged came from the Tooting Nurseries, the best plants being *Dielytra spectabilis*, *Spiraea japonica*, *Narcissus Bulbocodium*, and *Iris nudicaulis*.

ROYAL HORTICULTURAL SOCIETY.

GREAT SUMMER EXHIBITION, MAY 27 to 30.

Thus, the most important meeting at South Kensington during the season, was opened on Tuesday last, and, notwithstanding the unpropitious state of the weather on the opening day, a numerous company visited the exhibition during the afternoon. The usual spacious tent and a supplementary one leading from it to the entrance of the Council-room were crowded with floral treasures, and at a glance we were at once convinced that in point of number and general excellence of the exhibits, they quite equalled those shown on former occasions, and their arrangement on the gracefully undulating surfaces under the large tent left nothing to be desired, as, viewed from any point, the effect was charmingly picturesque, though the absence of the usual central group was conspicuous, as hitherto it had been a prominent feature, but this desideratum on this occasion was apparently unavoidable.

First-class Certificates were awarded to the following plants:—

Fritillaria recurva (Elwes).—A species from California, and one of the most beautiful of all the cultivated kinds. Its stems grow from 8 in. to 9 in. high, and are terminated by several drooping bell-shaped blossoms, which have recurved segments varying in colour from pale reddish-orange to bright orange, copiously spotted in the inside with bright red in the finest varieties.

Cypripedium pubescens majus (Elwes).—A large-flowered form of this handsome hardy Lady's-slipper, and a very desirable acquisition for the bog garden and other damp places.

Amaryllis Lady Louisa Egerton (Speed).—A pretty variety bearing an umbel of large flowers having reflexed segments, bluish-white, heavily streaked with deep magenta.

Azalea pontica Graf Von Moran (Veitch).—A delicate bluish-tinted variety, very similar in form to the singular kind called *narcissiflora*, to which we have previously referred.

Gloxinia Duke of Connaught (Veitch).—A pretty addition to dark crimson-flowered kinds, the blossoms of which are of good form, edged round the top with white.

Croton Evansianum (Veitch).—A handsome novelty, good in habit, and having bold foliage, somewhat trilobed in form, and richly variegated with yellow and crimson and various shades of green.

Azalea Madeline (Turner).—A first-rate variety, with flowers of fine form and large size, and pure white in colour, spotted with pale green, and remarkably free both in growth and flowering.

Besides these, several other novelties were exhibited, amongst which were *Primrose Cloth of Gold* (Carter), a sulphur-coloured double-flowered variety; *Magnolia Soulangiana nigra* (Veitch), a dark flowered form, with which were cut blooms of type for comparison; *Azalea mollis* Arthur de Warely (Veitch), a pretty bright yellow-flowered kind; *Dracena Laingi* (Veitch), a handsome table plant; *Pelargonium* Baroness Burdett Coutts (Sawyer); *Clematis Blushing Bride*, the double-flowered variety of *linguosa*, and *Begonia metallica* var. (Dixon).

A cultural commendation was awarded to *Dendrobium Falconeri*, and a couple of small plants in flower of the Nepalese Poppy (*Meconopsis nepalensis*) from Chiswick were highly commended.

The class for twelve new plants was represented by three exhibitors. The best came from Mr. Bull, who furnished a grand mass of *Dracena Goldiana*, fine plants of *D. Willisi*, *Dieffenbachia Shuttleworthi*, *Anthurium Veitchii*, a few fine examples of *Nephrolepis Duffii*, *Lomaria discolor* var. *bipinnatifida*, and *Croton roseo-pictum*; *Cycads* were represented by *Encephalartos Frederici-Guilielmi*, *Bowenia spectabilis* var. *serrulata*, *E. Hildebrandi*, and the elegant fine-flowered *Palm*, *Thrinax parbadensis*, and a fine pan of the brilliant-flowered *Hæmantis* Kalbreyeri, which quite enlivened the whole group. The next collection in order of merit came from Mr. Wills, who had good plants of *Croton Queen Victoria* and *C. Prince of Wales*, *Pritchardia grandis*, the graceful *Dracena Anerleyensis*, *D. terminalis* alba, *D. majestica*, small plants of *Nepenthes Courtii*, *Acalypha mosiaca*, *Dieffenbachia Shuttleworthi*, and the novel-looking *Ficus Grelli serrulata*. Mr. Williams contributed a group containing well-grown plants of *Croton Prince of Wales*, *C. Williams*,

and *Microlepia hirta cristata*, and the elegant *Gleichenia dicarpa longipinnata*; also *Dracena superba* and *Cupania elegantissima*, the bright-flowered *Azaleas* Mrs. Carmichael, Prime Minister, and others. The prizes offered by Mr. Bull for plants sent out by him since 1876 brought forward three exhibitors in the amateurs' class, but the exhibits were but of ordinary size. The first prize group contained *Dracena Robinsoniana*, D. Goldieana, D. vivicans, and D. Rex, the graceful *Aralia filicifolia*, *Kentia Wendlandi*, and *Lomaria Dalgaimesia*, the prettily-variegated *Croton Williamsi*, C. Hendersoni, and *Dieffenbachia ilinita*. The second prize collection included some of the preceding, in addition to *Gymnotheca Raddiana*, *Panax laciniatus*, *Pitcairnia platyphylla*, *Chamaedorea formosa*, *Davidsonia pruriens*, *Croton Disraeli*, and a crested form of *Pteris umbrosa*. The next in point of merit consisted of small examples of *Brahea filamentosa*, *Dracena amboynensis*, *Croton Rex*, *Macrozamia Mackenzii*, *Gymnogramma Mertensii* var. *Dobroydensis*, and others just mentioned. In the nurserymen's class there were two exhibitors; the best came from Mr. Williams, who had fine plants of *Croton Disraeli*, C. Williamsi, and *Dereza Rex*; also smaller plants of *Cibotium pruinatum*, *Kentia Wendlandiana*, *Dieffenbachia Shuttleworthi*, *Dracena Robinsoniana*, *Calyptronoma Swartzii*, *Sadleria cyatheoides*, *Croton princeps*, and *Odontoglossum cirrhosum*. The other group was staged by Mr. Wills, which comprised *Gymnotheca Raddiana*, *Croton Challenger*, *Davidsonia pruriens*, *Croton Disraeli*, *Phenix rupicola*, *Lomaria Dalgaimesia*, *Encephalartos Hildebrandi*, in good plants; and smaller examples of *Dieffenbachia Chelsoni*, *Anthurium Veitchii*, *Panax laciniatus*, and a good pan of *Anectochilus concinnus*.

Roses.—Of these there was a fine display. Mr. Turner, who was first, furnished superb examples of *Celine Forestier*, *Charles Lawson*, *Duke of Edinburgh*, *Madame de St. Joseph*, and others scarcely less in size. The largest in Messrs. Paul & Son's collection were *Charles Lawson*, *Celine Forestier*, *Princess Mary of Cambridge*, and *Juno*, all of which were well-flowered and in vigorous health. The highest award in the class for twenty was also won by Messrs. Paul & Son, whose group contained several large and well-bloomed examples; Mr. C. Turner and Messrs. H. Lane & Son, of Great Berkhamstead, gained the other prizes respectively. The amateurs' class for six was better filled than we have hitherto seen it, three exhibitors having shown in it, and though the plants were somewhat small, they were examples of skilful culture, and well selected as to variety. From Messrs. Veitch's establishment came a splendid and numerous display of pot Roses, not for competition, including many of the newer varieties. These were interspersed with plants of Japanese Maples in rich variety, from the undivided-leaved kinds to the delicately-cut foliage of *Acer dissectum* and others, all varying in colour, from a pale yellowish-green to a deep coppery tinge. The effect of this arrangement was charming, as the graceful contour of the Maples relieved the formal appearance of the trained Roses, the gay tints of which were also toned down, as it were, by them. Cut blooms of Roses were also contributed from the Waltham Cross and Cheshunt Nurseries, from which latter came also a group of pot Roses, not for competition, all of which were much admired.

Miscellaneous Plants Arranged for General Effect.—In this class it need scarcely be mentioned that Mr. Wills was first. The arrangement of his group was strikingly effective, though it differed materially from that designed by him last year, and which was so much admired. It occupied a semi-circular position at the end of the tent, and consisted of a background of tall Palms, Tree Ferns, Cycads, &c., amongst which the elegant leaves of the tall *Cocos flexuosa* had a pleasing effect; from these the gentle slope on which the group was arranged was thickly carpeted with various kinds of plants, from the common Creeping Jenny to the choicest Orchids, but though arranged promiscuously, all harmonised with each other charmingly. A splendid plant of *Nepenthes Hookeri*, with dozens of its pendent pitchers, was raised in the centre. Immediately behind this was a fine plant of *Cocos Weddelliana*, whose graceful foliage admirably contrasted with that of *Phyllocladus Lindeni* and other Aroids, *Dracenas*, &c., the somewhat sombre foliage of which was relieved by an undergrowth of *Calceolarias*, *Pelargoniums*, *Gloxinias*, *Odontoglossum vexillarium*, O. Alexandrea, and others all intermixed with such elegant subjects as *Adiantum gracillimum* and A. cuneatum, *Drosera binata*, with an edging of *Selaginella* to hide the pots. The next group in point of merit was that shown by Messrs. John Laing & Co., which consisted of well-grown *Azaleas*, *Caladiums*, *Begonias*, *Palms*, *Gloxinias*, &c. An extra prize was awarded to Mr. Aldous for a group of a somewhat novel character, consisting of small Ferns, *Palms*, *Deutzias*, *Lily of the Valley*, and *Spireas*, with a predominance of double white Stocks, all arranged on a dense sloping bank. The other groups, though well disposed and containing many choice subjects, require no comment, except that of Messrs. Veitch & Sons, whose small but excellent collection of new and rare plants was highly interesting and much admired. Amongst them a collection of

insectivorous plants claimed considerable attention, as did also a choice selection of Orchids, including the rare *Epidendrum syriacum*, *Dendrobium infundibulum*, D. Bensonae, *Aerides Veitchii*, and others; also cut blooms of the quaint but beautiful hardy *Iris iberica*, plants of *Saxifraga pyramidalis*, and an *Azalea* named *Flambeau*, of a rich deep crimson. A grand bank of the finest varieties of *Clematis* was shown from the Woking Nurseries, and was deservedly much appreciated, as the plants composing it were models of high-class culture. A noticeable feature of this exhibition was some plants arranged in boxes for windows, a purpose for which they are admirably adapted and extremely effective, as their habit is so graceful and their colours so bright. A choice group of well-grown new and rare plants was shown by Mr. Williams in the long tent; it consisted of *Dracenas*, *Crotons*, *Palms*, and other fine-foliaged and flowering plants; also a very fine mass of *Coleus Kentish Fire*.

Fine-foliaged Plants.—The amateurs' class for these was well filled and the exhibits good. The first prize group consisted of a grand plant of *Cycas revoluta*, a highly-coloured and well-grown specimen of *Croton interruptum revolutum* and variegatum, huge examples of *Areca sapida*, *Latania borbonica*, *Zamia Lehmanni* and *Dasyliodon glaucum*. Fine examples of *Dieffenbachia Bausei*, *picta*, and *Croton variegatum* were conspicuous in the second prize group, and a grand mass of *Dieffenbachia picta* in that which was third. Ferns, which may be included in this class, were remarkably fine; indeed, some of the plants in the group which gained the highest award were of a size seldom seen, such as *Todea superba*, of which a plant over a yard through was shown; *Gleichenia microphylla*, G. Mendelli, and *Cibotium Schiedei*. The next in point of order consisted of fine plants of *Davallia Mooreana*, *Gleichenia glaucescens*, *microphylla*, *Cyathea dealbata*, and others. In the nurserymen's class for six there was but one exhibitor, whose plants were of high-class merit, comprising *Gleichenia rupestris*, *Spelunca*, a fine plant of *Adiantum Farleyense*, *Davallia Mooreana*, and *Alsophila excelsa*.

Azaleas.—The competitive classes for these were numerously represented both by amateurs and nurserymen; the best eight in the former being remarkably evenly matched, and perfect as regards profusion and size of blossoms. In the nurserymen's class for eight the highest award went to the group from the Slough Nurseries, the plants in which, though but of moderate size, bore very fine flowers in good variety and rich in colour. The open class for fifteen brought six competitors, but even the first prize collection contained only ordinary specimens.

Orchids.—These were both in point of numbers and cultural merit below the average of former years. The best in the class for ten came from Mr. B. S. Williams, who showed *Cattleya Mendelli* with eighteen blossoms; C. Mossiae, with seventeen; *Masdevallia Lindeni*, with over three dozen; also fine examples of *Lelia purpurata*, *Cypripedium Swianium*, *Vanda suavis*, *Odontoglossum Pescatorei*, and others. The open class for fifteen was closely contested, the finest examples in the best group being *Dendrobium nobile*, a grand plant; *Cattleya Varneri*, *Masdevallia Harryana* and its brilliant coloured variety *Whitbourneana*; while in the second group the best were *Cattleya Mossiae*, *Oncidium crispum* var. *grandiflorum*, *Dendrobium Wardianum*, and *Lelia purpurata*. In the class for a group of *Odontoglossums*, Mr. Bull was the only exhibitor. His collection, which was tastefully intermixed with *Adiantum gracillimum*, and others, with a background of *Palms*, *Cycads*, &c., consisted of well-flowered examples of *O. vexillarium* in rich variety; O. Pescatorei, O. Alexandrea, O. Andersonianum, O. citrosum, and others.

Stove and Greenhouse Plants were well shown. The best group of twelve in the nurserymen's class comprised capital examples of *Erica depressa*, *Pimelea*, *Hendersonia*, *Hedera fuchsoides*, *Aphelaxis macrantha purpurea*, and others. The same exhibitors were also first in the class for eight. The group which gained the highest award in the amateurs' class contained excellent plants of *Hedera tulipifera*, *Erica depressa*, *Azalea Iveryana*, and A. Magnet. Heaths, as we have had occasion to remark at other exhibitions this season, were inferior to those shown in previous years, and the class contained but two entries.

Tuberous-rooted Begonias.—These were a source of much attraction, and were deservedly much admired, as perhaps never before have such excellent groups been staged, particularly those from the Stanstead Park Nurseries, in which they are made a speciality. Those to which the first prize was awarded included flowers with various shades of colour, from bright canary-yellow to the brightest vermillion. Amongst the most conspicuous varieties were J. W. Farrand, Marquis of Salisbury, Calypso, Princess of Wales, Princess of Denmark, and Massange de Louvre, all excellent single-flowered kinds; the best of the doubles shown were *Paeoniiflora*, *Comtesse H. de Choiseul*, and M. Keteleer.

Gloxinias.—Of these the best came from the Anckerly Nurseries, and amongst them were some extremely beautiful varieties remark-

able for their large size, good form, rich colouring, and position of the blossoms, which are neither too erect nor too horizontal, while the plants were compact and vigorous. The second prize collection was well named, and on the whole was good, as was also a collection from the Society's gardens at Chiswick.

Pelargoniums.—Both show and fancy varieties of these were, as usual, shown in grand style by Mr. James, of Redles, the plants being of large size and well flowered. This exhibitor occupied the first position in both classes, and Mr. C. Turner, of Slough, the second.

Hardy Flowers.—The best of these were *Narcissus Bulbocodium*, *Spirea japonica*, *Dielytra spectabilis*, *Saxifraga Maweanae*, *Pinguicula grandiflora*, fine masses of *Orchis maculata superba*, and the beautiful *Dianthus neglectus*. Cut blooms of hardy plants were also contributed. These included *Aponogeton distachyon*, *Pyrus floribunda*, *Caltha palustris* fl. pl., and *Doronicum austriacum*. The second prize collection were *Spirea palmata*, *Pulmonaria virginica*, *Corydalis nobilis*, *Cypripedium spectabile*, Double Pheasant's-eye *Narcissus*, &c. Cut blooms of Pansies were contributed by two exhibitors, and contained some strikingly beautiful varieties, richly coloured, of large size, and good in form. An interesting and beautiful group of hardy flowers was contributed from the Fulham Nurseries, not for competition, which received its full share of attention, as it contained many choice examples, both in Alpines and the larger-growing hardy plants.

Fruit.—This, on the whole, was inferior to that which we have seen here previously. Though the entries for Grapes were numerous, they contained no remarkable examples. The first prize for Black Hamburgs was awarded to well-coloured and fair-sized bunches, and scarcely inferior were those which gained the second award. White Muscats of Alexandria were but poorly shown, the three bunches in the competition for the second prize being disqualified, as they were Foster's Seedlings. Buckland Sweetwater was well shown. Pine-apples were poorly represented; the first prize in the class for two was withheld; the second was awarded to a pair of the Charlotte Rothschild variety. Pines shown singly were also inferior, with the exception of the Smooth Cayenne. Strawberries were shown by several exhibitors in fine condition. The best three dishes consisted of Sir Charles Napier, Sir Joseph Paxton, and President. The first prize for one dish was awarded to fine fruits of Sir Joseph Paxton. Peaches and Nectarines were represented by one dish of the former and two of the latter; but they were not very remarkable. Cherries were well shown from Lord Carington's garden; the class for two dishes consisted of fine fruits of Elton and Black Circassian; the latter variety was shown also in the class for one dish. Melons were abundant, and well grown. The first prize was awarded to Windsor Gem, the second to Hybrid Queen Emma, and Read's Scarlet Flesh took the third. Tomatoes were excellent, the dish to which the first prize was awarded being fine fruits of Improved Trophy.

Vegetables.—Two exhibitors staged collections of vegetables in two kinds, both very good, the best containing excellent examples of Improved Trophy Tomatoes, Asparagus, and Tender and True Cucumber. The prizes offered by Messrs. Sutton & Sons were not numerously competed, as the class for three varieties of Melons and three of Cucumbers was filled by only two exhibitors, whose collections were very fine. The prizes for six dishes of Peas ($\frac{1}{2}$ peck each) were not competed for.

Amongst the numerous miscellaneous contributions of horticultural structures, implements, and garden appliances, we noted, at the entrance to the large tent, the pretty Statuette Fountain in terra cotta, with Ferns and other plants elegantly arranged in rustic work of tuft; this was contributed by Messrs. Dick Radcliffe & Co. Among those which were arranged in the corridors and in the grounds, we noted the Patent Heat Regulators from Messrs. J. H. Richards, Cheltenham, which is apparently a useful contrivance for regulating the distribution of heat through hot-water heating apparatus with great facility, and which was distinguished by a silver Banksian medal. A similar prize was awarded to Messrs. Foster & Pearson, Beeston, Notts, for samples of their Patent Slot Throttle Valve, and which was also commended for its simplicity. Messrs. Richardson & Co., Darlington, exhibited small models of planthouses, and erected a full-sized structure, with improved patent roof methods of ventilating, patent glazing, and samples of the French systems of shading. The same exhibitors also showed their Portable Glass Wall Tree Protectors, and several examples of Boilers. Boilers were also exhibited by Messrs. Smeaton & Co., Fulham. Moving machines were shown by Messrs. Crowley & Co., Sheffield, with their Invincible; and Messrs. Ransomes, Sims, & Head, Norwich, their Automaton; and the Excelsior by Messrs. Waite, Burnell, Huggins, & Co., Upper Thames Street; and Messrs. T. Mackenzie & Sons, Holborn Viaduct, The President. Specimens of wirework came from Messrs. Thomas & Co., Edgware Road; and Rustic

Garden furniture, &c., from the Panklibanon Furnishing Ironmongery Company; and a like contribution from Mr. J. Caven Fox, South Kensington. Some examples of Woolford's Portable Water Tank, made of galvanised iron, were shown, a very useful appliance for plant houses where much watering is needed. Messrs. Blake & Mackenzie, Liverpool, showed numerous articles, including Tebb's Universal Flower Pots, Garden Labels, Insect Traps, Machines for filling seed packets, Celery Collars, and other things. Samples of "Florvita" were exhibited by the inventors, Messrs. Prentice Bros., Stowmarket, and a collection of Royal Polytechnic Barometers and Scientific Instruments came from Messrs. J. Davis, Newington Butts. Flower Boxes with movable sides were exhibited by Messrs. Whitburn & Young, the sides of which were decorated by the Xylographic process. In addition to the above in the miscellaneous class numerous and exquisite examples arranged in elegant designs of skeletonised fruits, flowers, and Fern fronds were exhibited in the council room by Mrs. K. B. Cussons, Southport, and Mrs. M. Hodgkins, Hyde Grove, Manchester, to whose collection was awarded a silver-gilt medal.

A list of the prizes awarded at both shows, of which the foregoing are reports, will be found in our advertisement columns.

ANSWERS TO CORRESPONDENTS.

Diseased Cucumbers.—Can you inform me what is the matter with my Cucumbers? Plants of them in an early frame grew luxuriantly, and showed a plenty of fruit 3 in. long by Easter. The young shoots then began to show a curly and broken appearance as if they had not the power of further development. The fruit also began to show in the morning a gummy exudation, as well as at some joints of the stalks. The soil they are in is the same as that in which Cucumbers grew and bore good crops last year. The beds were well prepared, bottom-heat good, and watering and airing have been carefully attended to. Young plants of Melons, Cucumbers, and Vegetable Marrows from both old and new seed are precisely in the same condition, and the same is the case with the young who had young Cucumber plants from me in the same plight as myself.—A. G. [Your plants have caught the ordinary Cucumber disease, for the cure of which see p. 412. Mr. Fish recommends warm and liberal treatment.]

Cattleya Flowers without Sheaths.—Mr. A. A. Thorn (p. 423) need have no misgivings about his plants of *Cattleya Trianae* that have produced flower-spikes without sheaths, a circumstance, no doubt, caused through the plants being young, and not having acquired sufficient strength. It is a very common occurrence, and is usually to be met with in the case of pseudo-bulbs that spring from others that have been too weak to flower. That this is correct is proved by the fact that these sheathless spikes rarely produce more than one bloom; that is, when they belong to the one-leaved section, of which C. Mossiae may be taken as the best-known example. The flowers drooping is caused by the absence of the scape to support the stalks; but, if they had been tied to small sticks, I have no doubt they would have lasted as long as the others. I have seen *Cattleyas* that have become weakened by any of the many causes that reduce them to such a condition—such as loss of roots, or in the case of the leading buds being eaten out by slugs—flowering in the way described; but, as soon as they regained strength, the disposition to do so disappeared.—T. Baines.

Roses at Cannes.—When at Cannes lately I saw in the Jardin Mazelle a Rose with flowers somewhat resembling the common Dog Rose, but with larger and whiter petals and yellow stamens. It was freely covered with bloom, but was most remarkable for its rich evergreen foliage, resembling in colour and glossiness that of a Camellia. They informed me that it came from Japan, and was called Rosa alba Camellia. Is such a plant known in England? It makes a beautiful shrub.—J. THOMAS. [Doubtless the Ramanas Rose of Japan (*Rosa rugosa* alba), figured in Vol. IX., p. 452, OF THE GARDEN.]

Seedling Pansies.—O. C.—Your seedling Pansies, which have been growing all the winter in open beds, and which are now flowering freely for some weeks, belong to a good strain, being rich and well varied in colour, and of good substance.

Books.—E. J. M.—"Greenhouses for the Many," 171, Fleet Street.

Names of Plants.—G. T.—1, Sedum, probably stoloniferum; 2, S. lydium; 3, S. brevifolium; 4, S. albaescens. *Moss* O.—1, Sedum pulchellum; 2, Saxifraga Alzoon; 3, *Troilus nappellifolius*; 4, *Triteleia arvensis*, which is *Hedera* is a variety. *T. H. F.*—Send them when in flower; plants cannot be named with any kind of certainty from leaves alone.

Questions.

Salt on Stone.—I would be glad if any of your readers, who are posted up in such matters, would kindly say if occasional dressings of salt to "Yorkshire Flags" or other stone would permanently injure the stone. The stones and slabs are black and discoloured from the prevalence of a minute Lichen which grows on the flags, as well as from the deposition of "soot blacks," with which our atmosphere is always charged, and I noticed last summer that where a quantity of salt had been spilled on the slabs in going over the walls, the stone was thoroughly as if it had newly left the mason's chisel, and I thought of applying it more extensively if it would not damage the stone. Hitherto, the cleaning has been done by stone-rubbing, but the labour is great and only partly efficacious.—J. S. W.

International Horticultural Exhibition.—A meeting of horticulturists, convened by Mr. Wills, to consider the advisability of holding an International Exhibition next year, was held in the Albert Hall last Tuesday, at which, after some discussion, it was agreed that the committee which had previously been appointed should be asked to re-consider its decision, which was, that it is inexpedient to carry out such an exhibition during the ensuing year.

Vol. XV.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

M. ANDRÉ ON LANDSCAPE GARDENING.*

M. EDOUARD ANDRÉ's scientific and elaborate book on the art and science of practical and landscape gardening is a voluminous work of eight or nine hundred pages, prepared with all the usual severity of minute detail so common to our exact and painstaking neighbours across the English Channel. The work is divided into twelve chapters, and these are again divided and sub-divided in a manner most commendable and helpful for general reference. The author unites the two professions of architect and landscape gardener, and, judging from the work before us, he appears to be freely patronised in both capacities. It was hardly to be expected that the author would restrict himself to a narrow practical treatise on so tempting a subject. We are, therefore, furnished with an historical sketch of the gardens of antiquity and the general progress of garden art in Europe up to the present time, more especially as it relates to the condition of landscape gardening in France. The gardens of antiquity, so far as history enables us to judge, consisted exclusively of parallel and rectangular forms. There is much truth and some exaggeration in the statement made by high authority to the effect that wherever in the art of any country variety is made to predominate it may safely be inferred that art has long been cultivated in that country; and, on the other hand, wherever the love of uniformity prevails it may, with equal safety, be inferred that in that country people are but in the first stage of improvement. It is, of course, natural to believe that in the infancy of art, when the attention of mankind was first directed to works of design, forms should be selected capable of most strongly expressing the skill of the artist, and the surest mode of effecting this would be the adoption of designs expressive of uniformity. When, therefore, it began to be considered that a garden was an object capable of beauty and of conferring distinction on its owner, it was but reasonable to expect that the earlier efforts should be directed with a view to render the designs as unlike as possible to the natural scenery of the country around, and thus to display more forcibly the amount of labour and expense thus bestowed. It is an interesting fact that the history of antiquity records no single instance where this character of uniformity has been deviated from in any spot considered solely as a garden; nor till within the last couple of centuries or so does it appear to have been imagined that a garden was capable of any higher aim than that of utility and uniformity in design. So also, in process of time, when art had made some feeble progress, and garden decoration had begun to be employed, it was exclusively restricted to such objects as regular cascades, grottoes, and trees cut into the form of animals. So tenacious, indeed, are the habits of popular taste, that these and similar objects, such as vases, urns, statues, and the like, made of cheap and perishable material, are still held in estimation and valued as objects of decoration. Any or all of these may undoubtedly be employed in accordance with the purest taste; but it requires the hand of a master to deal satisfactorily with a matter so fraught with delicate difficulty. It is not too much to say

that many an English—and French garden, too—otherwise beautiful, are rendered hideous by the introduction of meretricious objects, such as commonplace vases and the like, supposed to be ornamental. The plea for this slight diversion is the fact that the matter in question is vital to all that is simple and pure in taste, and needs to be repeated again and again, in the hope that this most prominent and national blemish may disappear from both English and Continental gardens.

In the elaborate and thoroughly exhaustive work before us, the editor, as already stated, has divided his matter into twelve chapters, and the work is embellished with eleven coloured plates and 866 engravings. The latter are employed to illustrate and aid the more complete explanation of the letterpress, and the former as exemplifications of the style in which the author has carried out the eleven examples in question, consisting of public parks and private gardens. The minute and persistent exhibition of detail accompanying the illustrations of this work is a marvel of patient perseverance, and thoroughly characteristic of the exact and methodical habit of the French mind. But while we can thus speak with unmeasured satisfaction of the unsparing labour and care with which the detail and the general execution of the work has been carried out, we extremely regret that a work of such pretensions, and an author so sure to be followed, should possess such wide influence in the dissemination of a style of gardening so utterly faulty as most of his published plans portray. What we specially refer to is the singular monotonous uniformity of the lines of his roads and foot-paths; but most of all the deliberate indifference with which he treats one of the chief charms of garden landscape, namely, breadth of effect. Instead of seeking where he may quietly lead his roads and foot-ways amongst groups and near boundaries, they are made to cross and recross again and again what should be broad and undisturbed open lawn. As an example of this, see Plate IV., page 385. We utterly repudiate the idea that there is anything English in this style of monotonous circles, for it is an acknowledged creed in English landscape gardening that roads and foot-ways must ever be held subordinate to the requirements of utility, and never introduced except where necessity demands them; but, in looking at the finished plans in the book before us, it would seem as if the gardens had been made in order to provide the means for a display of roads and foot-paths.

We make these remarks with no other feeling than an earnest desire that the author, who has so much in his power for good or evil, may be induced to restrain the redundancy of his intensely artificial flowing lines, roads, and foot-ways, and study more the less artificial and more agreeable forms of Nature.

R. MARNOCK.

AMONG the many changes in France during recent years nothing is more striking than the improvements made in the public gardens of Paris. Not only have these been made on an extensive scale, but quite different from the old French style of landscape gardening, as illustrated at Fontainebleau, St. Cloud, Versailles, and other well-known gardens. This style, the old style, not only was the rule in France, but was adopted in many other royal gardens throughout Europe. Happily for the art of gardening, all the newer gardens in Paris have been arranged upon a totally different principle, and, as any impartial person must admit, with considerable taste and judgment. The large parks and the minor ones, the squares, and even the small "places" designed during the time of the Second Empire and up to the present day, have been formed with a view to the natural development of the trees and objects

* "L'Art des Jardins." *Traité Général de la Composition des Parcs et Jardins* par Edouard André. Paris: G. Masson, Éditeur.

contained therein, and not wholly forgetful of the repose, verdure, and variety desirable in such places.

The newer style has been adopted in all recent changes to the entire exclusion of the old formal one. The fact that a garden is formed in immediate proximity to buildings does not compel the designers to make it formal in obedience to any laws of association, of which we have all read in books on landscape gardening, and the result is that these little gardens in the heart of cities, and often against some of their great public buildings, have a charm of freshness which could never have been secured in any other way. I know of nothing in city gardening more instructive than one of those oases right close against some large church, or plunged, as it were, amid public buildings, or surrounded by lofty houses, the Grass bright and fresh, and the fine-leaved plants and the trees and other plants in abundant foliage and flower. These gardens were, I believe, originally based upon what used to be called in France the English style, but were marked by features which could hardly fail to be studied with advantage by any one interested in the subject from this side of the Channel. The novel features of such have often been described in *THE GARDEN*—their good, as well as what would seem their objectionable, features. With the formation of these gardens the author of the book under notice had much to do.

It was desirable that so marked an improvement should some day find expression in the literature of the subject, and now

M. André has stepped in and has thoroughly executed this part of the work. For a long time no important work on landscape gardening has appeared in France, or elsewhere that we know of, except the work of Alphaud, which is mainly the publication of the plans, sections, and details of all kinds of architectural work done in the public gardens of Paris. The present book is really an important step in advance in various ways, and therefore worthy of the attention of all students of landscape garden art. It is a general book on the subject much more than the illustration of the work of any particular school or period. Thus we have the usual illustrations and dissertations on the gardens of antiquity—the Villa of Pliny, &c.; the Middle Ages, and so on down to recent times, including a long account of English landscape gardening—a long chapter on æsthetics, one on the love for nature, the principles of garden composition, in

which the author begins to be useful in his drawings, sections, &c. This is, indeed, one of the best features in the book, viz., that it gives sections and small cuts showing the simplest implements, and practical details of operations such as have not been given in any other work of the kind. This idea is carried out even to the extent of giving minute details of every plantation in some of the places described.

The chapter on views is well worth reading, and M. André takes up the defence of old trees against those who cannot resist the temptation of destroying them without absolute necessity. He considers all such trees should be preserved so long as there is the slightest doubt as to the good that would result from their suppression. The artist, he considers, should make for them every sacrifice, and modify his plans so as to make the best use of their noble or picturesque forms. He may show his love for such trees by even preserving those already dead, and covering them with hardy

creeping plants, and he cannot too much study the full effects of cutting down fine trees before the hatchet is put to one of them. The hatchet, in a few instants, may destroy the work of many years. But we must not fall into the other excess. He very properly considers that no good work is possible in a woody district or situation without sacrificing trees if they are too thickly placed and are injuring each other in effect or health; if they hide beautiful views, if they cover a mound across which a view is desirable, or occupy the bot-

Artificial Rock Gardens: Stream Entering Stalactite Cave in Paris Park.

bottom of a ravine in which a carpet of turf may be required, if they cover a house or make it moist, their destruction should be decided upon, particularly in such cases as those in which fine trees generally remain.

An excellent feature of the book is the contrast of what the author considers good and bad forms. This he carries out in the case of plans, entrances, drives, water margins, and in various other ways to the great profit of the reader. M. André is a thorough student of the literature of the subject, and frequently illustrates the designs of others to explain his point. I notice, for example, a tracing of a good and well laid out English garden on page 394, and one of a most elaborate Continental one on page 396, the author justly pointing out the difference between them—except that it seems to us the absence of needless drives in a park need not by any means sacrifice the “promenade” in the park; nor the

contrary, that would seem to us to make it far more agreeable and not less extensive. Referring to the "wild garden," the author, says M. André, "preaches an introduction and naturalization in our woods and in shrubberies and masses in our parks of a great number of exotic species, of which a part only could resist, without reduction, the invasion of the natural vegetation." The fact is, that such is the number of vigorous hardy exotic plants, that destruction, through their aid, of the native vegetation would in many cases be quite possible if desirable. The whole northern temperate world is full of types of plants as vigorous, and even more vigorous, than our native ones, as, for example, the Golden Rods, Cow Parsnips, tall Mallows, Bupththalmum, Globe-flowers, Giant and Globe Thistles, Compass plants, and a host of other strong plants too numerous to mention, of the same type; while numbers of smaller plants are equally difficult of extermination if the situation in which they are placed be studied.

It is impossible in so short a notice to do justice to a book

so full of interest, so well produced, and so practical. If we have any feeling of disappointment in the book, it is only that details are far more predominant in cuts and illustrations, &c., than sketches of the best results attained. In this respect the book does not quite do justice to the best modern work in France and elsewhere. It would have been well to have given a large number of artistic illustrations, showing the breadth, variety, and picturesque of

the best modern gardens, which many people cannot understand from plans. But this is perhaps asking what is not reasonable, as the book is most liberally illustrated (some of the woodcuts in which we reproduce), and, as usual with important French books, well printed.

W. R.

Woodland Wild Flowers.—The wild Scilla or Blue Bell is just now in great beauty, but even this is as late this season as other plants; last year I saw immense masses of it in full bloom in the first week in May, and now the end of the month is reached ere its full beauty can be seen. Not so common, but not less striking when seen in a mass, is the deep reddish-purple Orchis. Of this I saw a few days since in a meadow a large clump so fine as to elicit the warmest admiration. The spikes of bloom were some 6 in. or 7 in. in length, and quite perfect. By the water-sides the large yellow Caltha is even more striking than some of our garden varieties of the Globe flower. The purple Ajuga is here and there in flower, and the Lady's Smock as well as many others. It is now a good time to wander about the fields and hedgerows to gather wild flowers, but not to rob the country of their roots, as is often done, even in the case of plants that are scarce.—A. D.

THE FRUIT GARDEN.

WINTER PRUNING.

Pear Trees.—Winter pruning is performed when the sap of the Pear tree is at rest, except during severe frost. The operation may take place as soon as the last leaf has fallen, especially in the case of weak, old, and worn-out subjects. On the other hand, the pruning of subjects which show a strong tendency towards a luxuriant growth of leaves rather than towards a good show of fruit should be deferred until the sap begins to rise. There is no harm in pruning the same tree at different times of the year, the main branches in the autumn and the fruit-bearing branches in the spring. The amount of wood to be pruned away depends on the nature of the tree, on its strength and growth. For instance, we must prune less closely those subjects which are of vigorous growth, which produce but little fruit, and ramify freely, as well as those intended for large trees, or which have been grafted on free stocks. Generally speaking, we must prune less closely in cold climates than in warm, the locality, soil, aspect, and situation being taken into consideration. The principal branches of the tree should be left pretty long. On the other hand, the Pear grafted on the Quince should

be closely pruned, as well as those subjects which are intended to produce a large number of fruit-bearing shoots, a remark which will also apply to the topmost branches of the tree. Too frequent and too close pruning will injure a weak subject, while in the case of a vigorous tree its fruit-bearing capabilities will suffer severely; besides which, canker is almost sure to set in.

The direction in which the branch grows should govern the amount of pruning to be given to it. For instance, branches that are much inclined towards the horizontal should be sparingly pruned, while those which grow in a vertical position may be

thinned out with advantage to their neighbours. If we find ourselves under the necessity of pruning but slightly an upright branch belonging to a variety that ramifies but feebly, we may pinch off or cut with the pruning knife the two eyes nearest the top of the twig, at the same time cutting away a portion of the rim above the lowest eyes in the form of a horseshoe. This is especially necessary when the lower shoots exhibit a tendency to spread. These remarks apply more particularly to Beurré Hardy, Louise Bonne d'Avranches, and Fondante des Rois.

In closely pruning a branch whose tissues have become hardened we promote its growth, but in suffering a weak branch to grow untouched we frequently make it weaker than ever. In any case it is admitted that with these and a few more exceptions pruning closely injures a branch, while leaving it unpruned strengthens it. Is not an unpruned Pear tree growing in the open far stronger than another tree of the same age pruned into the shape of a spindle? A healthy, robust-looking branch, if it is shorter than its neighbours on the same bough, and if it ramifies freely, need not be pruned—for instance, in the case of the Beurré Six, Nouveau Poiteau, de l'Assomption, and Comte Lelieur. In these instances a longitudinal incision will facilitate the expansion of the bark and the spread of the sap. The shoot is pruned down to the eye, the eye being chosen on the upper part of the branch if it is weak, below if the tree is a pyramid, and level with the eye if it is grown en palmette as a cordon or as a

A Garden in the South of France.

candelabrum; in fact, in such a direction as to follow the main branch.

When the tree has once begun to bear fruit, we must adopt a system of moderate pruning, or at any rate prune closely and sparingly in alternate years. It is, however, only experience, and above all observation, which can guide the fruit grower in the application of these general rules, and of the exceptions to them. Pruning the fruit-bearing branches is much more simple. It is sufficient that they should not be allowed to crowd together so as to make confusion; that is to say, the spaces between them must be regular. They are either cut or broken to a length of from 6 in. to 8 in. The type of a fruit-bearing shoot is a twig or small branch of medium thickness, and of the length of from 6 in. to 8 in., the eyes or buds of which are successively transformed into fruit, and which may be kept in proper condition, renewed and regenerated, so to speak, by judicious pruning. The perfection of Pear-growing is to produce an average of ten good fruit per annum per yard run of the principal branches. The eye of the Pear tree generally takes two or three years before it is converted into a fruit-bearing shoot, but in certain varieties which come, like the William, Duchesse, and Beurré Clairgeau, to maturity with great precocity, we may have fruit at the end of a year. In these cases the Pear-grower should not allow the trees to bear too many fruit. Other varieties, like the Beurré Diel, the Bon Chrétien, and the St. Germain, throw out shoots from the base. In such cases heavy pruning must be avoided, and the production of fruit must be insured by means of slits cut in the bark where the latent eyes are beginning to show themselves, and by pinching off the buds at the end of the fruit-bearing shoots. The stiff, upright shoots which are to be found in the *Triomphe de Jodoigne*, the Beurré d'Hardenpont, and the Bachelier, fruit on the upper portion, and thus, thanks to the natural smoothness of the bark, they do not become wrinkled at the base. We must beware of twigs which are too short, and of simple fruit buds growing immediately on the stem, which are deprived of the resource of buds to replace them, such as the *Doyenné d'Automne* and d'Hiver, the Beurré Gris, the *Passé Crassane*, the *Passé Colmar*, which show them sometimes, but they die off after flowering only once. The shoots must be made the most of in the case of the most productive varieties, in which the terminal eye grows more naturally into a fruit-bearing twig, such as the *Crassane*, the *Maré Louise*, *Josephine de Malines*, *Urbaniste*, *de Tongue*, *Seigneur*, and *Bergamotte Esperen*.

Water shoots are cut down on the heel to the thickness of a five-shilling piece. Adventitious eyes will swell at the base, but if they grow too long they may be pinched down to a single one. Old fruit-bearing twigs and branches are maintained in proper condition by incisions and pruning down with the sécateur so as to diminish their length and check ramification. While the sap is in full vigour during the summer, the usual operations to be performed are budding, pinching, twisting or breaking off the green shoots, all of which have their importance in keeping up a proper balance between the main branches of the tree and the amount of fruit produced.

CHARLES BAILEY.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Fruit Growing at Worksoop Manor.—Mr. Miller, Clumber (p. 372), will doubtless be pleased to hear that the Vines at Worksoop Manor, to which he alludes, are still in the very best condition. I was shown through the forcing and other houses on the 21st of last month, and I found the crops of fruit (in all stages) very satisfactory. Grapes were ripe and well coloured, and of *Eggs* (Brown Ischia) there were heavy crops, and of Strawberries (of the James Veitch variety) there was a very fine display. Melons were ripe in quantities, of a useful size, about 3 lb., and finely netted; and Peaches and Nectarines, from ripe fruit down to the later varieties, were excellent. Mr. Miller, who is now at Clumber, thoroughly renovated the fruit department at Worksoop Manor before he left it, and, as will be seen, with excellent results.—J. JEFFERSON, *Worksoop*.

Grapes from Eyes Raised the same Year.—I am much obliged to Mr. Hobday for putting me right as regards Mr. Hardie's experiment in reference to this subject. I did not know, or had forgotten, that he contemplated fruiting the same Vines the following year, and which, I can quite believe, would have been too soon to expect a remunerative crop. I would only recommend the plan to be tried with pot Vines. In the same page (p. 440) objections are raised on the score of expense and accommodation in putting the plan into practice, which presupposes a conjunction of circumstances that are to a great extent imaginary. The crop secured by Mr. Henderson, of Thoresby, in this way did not cost a penny for extra accommodation, for the Vines were fruited on the side-shelves of the roomy Pine stoves there. As to my being in

error in saying that Mr. Hardie got a crop of Grapes from his Vines the same year in which they were raised from eyes or planted, I do not see it. My original statement (p. 325) was to the effect that Grapes were produced from the Vines of the same year, or "in nine or ten months after the eyes were put in." What Mr. Hardie did, was to take a crop of Grapes, about the new year or a little later, from rods that were not in existence in April, or in less than ten months from the time the cane had borne them broke bud. As to not looking upon such a result as "anything more than a cultural curiosity," as Mr. Baines expresses it, I need only observe that most people would regard a crop of Grapes at the rate of nine bunches to the young rod as a rather acceptable curiosity about mid-winter or later.—J. S. W.

Rapid Pine Growing.—In reply to "E. C. P." (p. 420), allow me to say that the Pine plants were rootless suckers when planted out in the pit; the variety was the Smooth-leaved Cayenne. List 4 contains no mistake, but positive facts, and I may add that I have had frequently as good results during the many years that I have grown Pines.—M.

American Cranberry Farms.—One of the largest Cranberry farms in the world is known as Sackett's Marsh, near Berlin, Wisconsin. It comprises 750 acres of marsh, about one-fourth of which is under cultivation. The yield has sometimes reached 35,000 bushels.

AN AMATEUR'S GARDEN.

You have given us some excellent advice as to an amateur's greenhouse; can you not do the same about an amateur's garden? This is a difficult question to reply to, and any attempt to answer it must be made at a considerable rate of failure. When you have a greenhouse before you, when you know well its capabilities, and can tell your experiences with it for some years, it is very easy to advise in reference to it. No matter where it is erected, it is not affected by climatic influences in one place more than others; the same plants can be grown in it with nearly equal chance of success in the suburbs of a smoky town or in the pure air of the country village, but when one comes to write about a garden, the whole thing is changed; gardens vary in size, character, situation, climate, soil, &c., in almost every item, and therefore the difficulty of giving advice is intensified. The tastes of their owners are multifarious, and in nothing, perhaps, is the old saying truer: *Tot homines totidem sententia*; and one has but the experience of one's own garden to show the truth of this, at one time having it on the top of a breezy cliff overhanging the sea, where nothing could grow, that once showed its head above the projecting fence, at another time in a lovely valley where Nature had done her best to make gardening a pleasure, but where a light sandy soil made it a difficulty; at another time in the back garden of a watering-place villa, not 40 ft. square, and then, again, in a piece simply fenced off from a field, and in all and under all circumstances having to contrive how economy could be practised in the carrying out of a favourite pursuit, the love for which has no way diminished as years have gone by, and one which, in times of sorrow especially, has ever been a comfort. Like angling, it affords time for reflection and communing with oneself, and to the overtaxed brain or overburdened heart there is in it ever a wellspring of comfort. It is not the worrying of exhibition, but the culture of plants, that ever gives a return for the care bestowed on them, that constitutes the pleasure of gardening.

In giving, therefore, any hints on the formation or keeping up of a garden, my own varied experience would hinder me from taking any one particular type as a pattern, but would rather lead me to put forward some general principles which may be applicable to all, and in the course of these few remarks I may, perhaps, state some things which may be of use, premising that I have in view those who do not employ a professional gardener, who work at it much themselves and superintend all.

The first point, I think, in entering on a new garden is to ascertain what is the character of the soil, and what plants suit it best. Educated gardeners are supposed to know all these things, but amateurs do not, and oftentimes make mistakes in consequence. Suppose any one like myself with a great love of American plants, as they are called, and seeing the gorgeous displays at Bagshot and other places, were to say I shall have a plantation of them; and have a garden or place on the chalk, we all know that the result must be failure; chalk is absolute poison to them, and much expense and trouble might have been saved had this been recognised. Again, on a stiff clay how hopeless it is to try and grow plants that require to root down deeply, and to be free from stagnant moisture, e.g., Lilies; you may dig out, fill in, and plant, but after all there will be failure; your Lilies will not grow, but dwindle away. Closely connected with soil is situation, and this has to be well considered. Thus in the

neighbourhood of a smoky town it is a real waste to try and grow Roses. They drag out a miserable existence, and are at the best poor half-starved things; and, indeed, this suitability or otherwise of soils goes a good deal further than some people imagine. Take, for example, Strawberries; it is not until you have tried that you find out which sorts will suit the soil, and then you have to adapt yourself to the circumstances.

My second piece of advice would be, do not attempt bedding-out or carpet gardening. I do not wage an indiscriminate warfare against these systems; there are some places where they are singularly appropriate. Our great public gardens are little frequented, except during the summer months, and then the gay and bright colouring of Pelargoniums, Calceolarias, Verbenas, and other bedding plants, or the neat geometrical patterns made of carpet plants are pleasing enough. The persons who look at them are passers-by, so to say; they are not amongst them continually, and hence their eyes do not get satiated with them, and the fine beds of Victoria Park or the sub-tropical gardening of Battersea could not well be supplanted by any other kind. In the garden of the Luxembourg, at Paris, a part used to be filled with mixed borders, and, however interesting, it bore an unfavourable comparison with the Parc de Monceau, or other places where the bedding-out and sub-tropical gardening were carried out. The same holds good, I think, with regard to the large country seats of our aristocracy. As a rule, during the spring and early summer months, the owners are away in London, and until Parliament is up they are not likely to be at home; to have then their gardens in a full blaze of colour is, no doubt, pleasing, and a herbaceous garden at that time would not present the same attractive appearance. The owners are only at home for a short time, and do not get tired of the gorgeous, albeit sameness, of colouring; but it is a different thing with the amateur, who has a small garden and limited means; if he carries out this system, then until June there is nothing to be seen in his garden but bare earth. The plants are bedded out in June; they grow on in July; are in their full beauty in August; and then their glory is departed—for two months, and the beauty of the garden for the rest of the year is sacrificed. It is idle to talk of spring gardens; limited space and limited means forbid this. Then if he has a greenhouse the greater portion of it has to be utilised for the growth of bedding plants, to the exclusion of many things which he would like to have, but which he can find no room for. I would not, however, have the garden depend altogether on mixed borders of hardy plants, but would so arrange them that space should be left for a certain quantity of Pelargoniums and other plants, which, planted amongst the others, will brighten up the borders, and thus make them attractive throughout the whole year.

A third point on which I would insist very strongly is not to try delicate or doubtfully hardy things; there is such a large number of plants of great beauty which are perfectly hardy, that it is unwise to waste time, money, and patience on things which dwindle away and die. Many persons have been tempted to try plants which are said to be hardy, and are so in ordinary seasons, but which perish in severe frost, that it is well not to try them. Bearing in mind the locality in which the garden is situated, choose then your plants accordingly. Plants may be grown out-of-doors in Devonshire and Cornwall which would perish in Lincolnshire or Yorkshire, or will succeed in a high and airy situation, but would succumb to the damp

cold of a valley not far off. I have seen Laurustinus killed to the ground in a low situation, while on an elevated spot close by they have not had a leaf injured. Many know the way in which Violas and Pansies thrive in Scotland and the cooler parts of the island, but in the hotter and drier districts they do not thrive; and, thanks now to the skill of the horticulturists, and the enterprise of those who cater for the public, there is such a wide field to select from that no one need be at a loss.

I would also advise any one who really loves flowers to have, if space permits, a rockery; it need not be very elaborate, it must not be cockneyish. Consult "Alpine Flowers"; in see that little work what style is to be avoided and what to be followed; there is a large number of most lovely plants which are lost in a border, or get overgrown by more robust things, which flourish well on a rockery, and which in the earlier months of the year amply repay any care bestowed on them.

And lastly, let me give as a golden rule, endeavour after tidiness in all your garden arrangements; a garden overgrown with weeds, or littered about with things that ought to have been put out of the way, loses one half of its beauty. That it is in certain places and times difficult no one can question; country gardens are more apt to suffer from weeds than suburban ones. If the garden be not walled it is probably surrounded with fields and hedgerows, the seeds from which are disseminated far and wide, while in the neighbourhood of a town where every inch is utilised and most gardens are walled in, the same liability to suffer from one's neighbours does not exist; then there are times when it is impossible to get on the ground, and the soil is so wet that hand-weeding is equally difficult. In such cases all weeds will grow apace, and the garden of necessity becomes untidy; but it is a matter to be most diligently attended to, not merely for the injury the weeds do to the garden, but because of their unsightliness, and the hoe is one of those garden implements which ought never to be allowed to rust.

In these observations I have had flowers more especially in my mind, but I am not sure that the same rules do not equally apply to the kitchen garden, and, indeed, in some small gardens, flowers, fruit, and vegetables are so mixed up together, that it is impossible to lay down rules that do not apply to all alike. What I have said may appear truisms, and it may be asked what need to put such things on paper?

but my own experience is, that it is the overlooking of truisms that often conduces to failure, and that if writers would not imagine that those for whom they write know a great deal more than they really do, they would often write more effectively; and I cannot close these remarks without quoting the words of one who will ever be considered an authority on all he wrote about, the late Mr. Rivers, who concludes the preface to the tenth edition of his "Rose Amateur's Guide" thus: "A practical cultivator, in writing on cultivation, labours under a disadvantage; he almost obstinately supposes that every one would know something relative to these, with him every-day operations; he is apt, therefore, not to go sufficiently into detail." I have strenuously endeavoured to resist this feeling, and humbly trust what I have written on this subject or on any other will be found sufficiently explicit. If that be not so, I shall have much pleasure in supplying such further information as may be asked for in order to make the subject on which I write clear.

DELTA.

Rocky Stair-way in the Parc des Buttes-Chaumont. (See p. 447.)

EFFECTS OF LOCAL INFLUENCES ON GARDEN CULTURE.

I REGRET to see by Mr. Baines' note on this subject (p. 404) that so eminent a horticultural authority as he is should think that my "conjectures as to the cause of Mr. Tonks' failures will not bear the test of a moment's reflection." Neither Mr. Baines nor Mr. Tonks himself will, I suppose, venture to assert that vegetation even of the hardest description receives no injury from chlorous, nitrous, or sulphurous fumes. That whole districts are laid waste by these deleterious gases is a fact that is patent to everybody. It only remains for me to consider the question of their being carried to a sufficient distance to affect Mr. Tonks' flowers injuriously. If either of my opponents will refer to the Blue Book containing the Minutes of Evidence given before the Royal Commissioners appointed to investigate the working of the Alkali Acts (Parl. Papers, c. 2159—1—1878) they will find some terrible stories touching the effects of noxious fumes not merely on herbaceous vegetation, but on forest trees. They will find that sturdy subjects like Oaks, Pines, and Weeping Willows are seriously damaged, and in some cases killed outright, by these fumes at between six and seven miles from their source; that fruit and Rose trees are withered up in a very short time at the same distance; and that chlorous fumes have been detected in notable quantities in the air at ten miles from the delinquent factory. I could, if space permitted, fill half a number of THE GARDEN with similar histories related to the Commission by farmers, horticulturists, doctors, land surveyors, and other witnesses belonging to all grades of society. It thus being proved upon incontestable evidence that Oaks and Willows are killed by noxious fumes at six and seven miles off, is it not perfectly reasonable to suppose that Mr. Tonks' flowers at Packwood, which is about ten miles from Birmingham as the crow flies, might be seriously affected by these enemies of the horticulturist? I trust, therefore, that Mr. Baines will now allow that my conjectures are worthy of some consideration. My opponents will, no doubt, say that flowers are grown in perfection under the very chimneys that give forth the fumes. This is a fact that I am perfectly aware of, and, as I write, I have in my eye half-a-dozen different charming spots within reach of the worst parts of Tyneside, the Black Country, Widnes Dock, and similar localities. But what does this all prove? Not that Mr. Tonks' flowers and plants are not killed by noxious fumes, but that Mr. Baines, the managers of the Birmingham Botanical Society, Mr. Tomkins, and a host of their fellow-workers are possessed of sufficient skill, patience, knowledge, and, above all, lengthened local experience, to grow plants in spite of the action of these deleterious agents. Such being the case, Mr. Tonks has every reason to hope that the evils from which he is suffering are to be remedied. If, as I always have supposed, and still suppose, the fumes from the Black Country are the cause of his failure, he may surely take heart in the fact that, with proper experience and skill, plants may be and are growing in the very thick of the vapours whose bad effects he must only feel in a greatly weakened form.

C. W. QUIN.

THE WINTER IN DORSET.

FROST this exposed situation—731 ft. above the sea—we are glad to be able to record few losses from the effects of the late exceptionally severe winter. Amongst climbers, *Passiflora corallina* is killed to the ground, but is springing from the root; *Escallonia macrantha*, *Bignonia radicans*, *Aristolochia Sipho*, and different kinds of *Clematis* are quite uninjured. *Ceanothus aureus*, *Jasminum revolutum*, and *Lonicera sempervirens* were only slightly cut by frost and keen winds. Lilies of various kinds have never looked better. *Crimum* capense, without even the protection of ashes, is growing well. Liums, such as *narbonense*, *salsoloides*, *alpinum*, and *flavum*, though late, are now shooting strongly. *Cyclamen europæum* has fared badly, every plant killed; as are also *Nierembergia rivalaris* and *Eryngium elburnum*. *Primula denticulata*, *purpurea*, *pulcherrima*, and *luteola*; *Epimedium colchicum*, *Veronicas*, and herbaceous plants generally are looking healthy. *Tupa Feuille* is pushing strongly, and has been out of doors, with only the protection of ashes over the roots in winter, for several seasons; it bloomed with us last year for the first time. *Echium fastuosum*, in a border, though carefully matted, has been killed, but plants of it have stood in a greenhouse with impunity where *Callas* were severely injured by one night's intense frost. *Aquilegia* (*chrysantha*, *cerulea*, *glandulosa*, &c.) have proved very hardy. On the whole, we congratulate ourselves here on the greater hardness of plants in this high and dry climate, though their growth may be less luxuriant than in warmer and more sheltered places. Common Laurels have not suffered at all, though the *Laurustinus* has been injured to some extent. At present, also, the prospect for wall-fruit is promising. The bloom, though remarkably late, has been unusually fine.

Ashmore.

K. L. DAVIDSON.

Rabbit-proof Plants.—In one of the earlier numbers of THE GARDEN I gave a list of herbaceous plants and shrubs which ample experiment had shown me to be practically rabbit-proof, and further experience has not given cause to diminish or materially to increase that list. "M. C. D." (p. 416) gives a list, in which he includes *Hollies* and *Laburnums*. Now, I have seen repeatedly *Hollies* more than 3 ft. in circumference, and *Laburnums* of equal size, gnawed and destroyed. Privets also are liable to be eaten. Plants of the bulbous type are rarely eaten, except the *Crocus*, which has not a chance; the others, *i.e.*, Lilies, Irises, Tulips, Tritomas, Lily of the Valley, Butcher's Broom, Solomon's Seal, Narcissi, Asphodels, Leucojums, Snowdrops, &c., are perfectly safe. So are the *Arum* family and most of the *Rose* tribe, *e.g.*, *Spiræa*, *Potentilla*, &c. *Heaths*, *Rhododendrons*, and *Azaleas* may be safely planted, though the latter are sometimes cut a little at first till the rabbits find out what they are. Of the *Primroses*, *P. japonica* is quite rabbit-proof and a noble plant for woodlands. Varieties of *P. acaulis* (veris) are safe, except the large-flowered *Polyanthuses*. *Auriculas* are greedily eaten. There are many rabbit-proof subjects among the *Ranunculaceæ* family, such as *Clematis*, *Columbine*, several *Anemones*, *Monkshood*, *Larkspur*, *Globe-flower*, and *Winter Aconite*. *Hepaticas* are eaten up directly, more's the pity, for they would grow as readily in our woods as in Switzerland. The *Hypericums* and *Peonies* are excellent things to plant out, and rabbits do not touch them. Your correspondent mentions *Cupressus Lawsoniana* and *Epimedium*, but they both suffer here; and of the *Hellebores* the best, the *Christmas Rose*, is destroyed at once.—SALMONICEPS.

PROPAGATING.

THE PROPAGATION OF BEDDING PLANTS FOR STOCK.

It may seem premature to refer to this matter now, but some things are much easier and better struck late in spring before the heat in the propagating bed has altogether declined. The cuttings will strike now easily, and such things as *Coleus*, *Iresine*, and *Alternantheras*, put in handy-sized shallow boxes, and after they are rooted if placed out of doors in some corner, the growth will be hard and firm, and will pass through the winter safely with a less expenditure for fuel than if all the propagating is delayed till summer or autumn. The variegated *Mesembryanthemum* is best propagated now, and it is difficult to get up a large stock of *Lobelias* from cuttings taken in autumn, and lifting and potting the old plants is a troublesome and not always a satisfactory proceeding; but if a few pots or a boxful of cuttings are put in now from the last batch rooted, or if the plants are coming into flower, the flowers might be cut off half-a-dozen plants and the plants shaken free from soil, when each plant will probably divide into a dozen or so, and if these bits are dibbled into a boxful of sandy soil and placed in a close frame, a hundred or so of small plants will be secured to form stock plants for another year. It is a long time to look forward, I know, but there is a saving in it. *Pelargoniums* and other subjects are of course best propagated in autumn. I am speaking more especially of those plants, such as *Coleus*, that require to be wintered in heat, and of that other class of plants, like *Lobelias*, that do not strike well in autumn or *Mesembryanthemum*, that, if not well established, are apt to damp off in a cool house in winter, and now every bit will strike, and it will be very pleasant, when the propagating season comes round next February, to have a good stock of healthy plants to work from.

E. HOBDAV.

Royal Horticultural Society.—We are requested to state that the special prizes offered by Messrs. Hooper & Co., John Laing & Co., Jas. Carter & Co., and Sutton & Sons, will be competed for on July 8 instead of June 24, as formerly announced. We have also been informed by Messrs. Sutton & Sons that as there was no competition for six dishes of Peas on May 27, the same prizes will be offered by them on July 8, and that the restriction as to the varieties will be withdrawn. The prizes offered by Messrs. Jas. Carter & Co. for vegetables and Peas have also been deferred until July 8.

Monstrous Pelargonium.—We have received from Mr. R. Gilbert, of Bughley, a remarkable monstrosity in the shape of a semi-double flowering *Pelargonium*. From the primary truss of flowers, which is large, have sprung a dozen or more secondary trusses, the whole making a huge pyramidal cluster 11 in. wide at the base and 7 in. high, a strikingly effective head of flowers being the result.

THE INDOOR GARDEN.

A NEW SARCOCHILUS.

Our illustration represents one of the most distinct of Australian Orchids, belonging to a genus of which but few known species are

handsome enough to secure a permanent position in our gardens. It was introduced by Messrs. Veitch about two years ago, and is named in honour of a zealous Orchidist, Mr. Fitzgerald, whose beautiful work on the Orchids of Australia is now in course of publication. This gentleman collected no fewer than sixty-two species of Orchids within a mile radius of Sydney, the capital of New South Wales, and his observations on the means by which some of the species are naturally fertilised by insect agency are largely quoted by Darwin in his "Fertilisation of Orchids."

The genus *Sarcochilus* was founded by R. Brown, and comprises a few Australian, Fijean, and Malayan Epiphytes "with short stems, narrow distichous, leathery leaves, and bracteated spikes or racemes of fleshy open and sometimes showy flowers."

The lip is three lobed, and the central division is peculiarly short, thick, and fleshy, and from this character the generic name is derived. The species here illustrated is of neat habit. It grows and blooms well in the Veitchian collection, planted in a fresh compost of peat, sphagnum, and crocks, the whole placed in a small Teak-wood basket, and suspended near the glass in an intermediate house. As, in the case of other true Epiphytes, its thick roots seem to enjoy exposure to the diffused light in a humid atmosphere and moderately warm temperature. In order to cultivate it successfully, it must, on no account be over potted, a very little fibrous compost in the smallest of Teak-wood baskets being amply sufficient for its requirements, and under these circumstances it makes a vigorous and healthy root growth, stout foliage, and produces spikes 1 ft. in length, bearing from ten to fifteen flowers. The flowers of different plants as imported vary in size and markings, but average 1 in. or more in diameter. The sepals and petals are nearly equal, of waxy whiteness, each marked at its base with a few transverse bars of rose inclining to purple, or what is known as port-wine colour. The lip is short, thick, and of waxlike consistence, white with a dash of lemon-yellow on the disk, and in some varieties a few minute rose-coloured dots are visible. The profile or side view of the flowers shows

them to be elegantly bell-shaped at the base, and, owing to their general form, colour, and concentric markings, as seen from the front, they call to mind the smaller forms of the South American *Odontoglossum Cervantesii*, or a small marked variety of the dainty little *Aerides japonicum*. Were the plant less rare it would soon gain for itself a place in our gardens as one of the neatest and

prettiest of all Australian Orchids, apart from the additional interest which it possesses as being the only introduced species of a little known genus at all likely to interest amateur cultivators of Orchidaceous plants. B.

New Australian Orchid (*Sarcochilus Fitzgeraldii*).

Untrained Azaleas.—

—In a careful examination of the several subjects brought together on the occasion of the last meeting at South Kensington, I stumbled, so to speak, upon an untrained Azalea, which afforded me more pleasure than I can well express, so much more beautiful was it than the hard-trained specimens invariably presented at exhibitions. This specimen was one of the old *A. indica* alba, and belonged to the Society. It was about 8 ft. in height and of a proportionate diameter, and it had been grown entirely in a natural manner; and, as it was densely flowered, it presented a most beautiful appearance. To compare it with the close-trained pyramids and the flat bushes presented by the majority of the exhibitors is absurd, so much more beautiful was it. It is said that unless Azaleas are trained they will not travel. No doubt the branches require some amount of steadying, but it is nonsense to say that Azaleas cannot be sent a few miles by road or rail without being trained in a manner that makes them but little short of hideous. I venture to say that Mr. Barron would, with the aid of a few stout stakes and a little bast, so secure the branches of the plant in question that it would travel to Scotland without half-a-dozen of its blooms being injured.—"Gardeners' Magazine."

Orchids at Norbiton.

—In the rich collection of these popular plants in Lord Londesborough's garden, we remarked the following in flower, viz., *Epidendrum cnemidophorum*, a rare species of the erectum type, with slender stems terminated by large, drooping clusters of blossoms, which are pink, copiously spotted with rich chocolate, and very showy; the lovely *Dendrobium infundibulum*, with its ivory-white and orange-coloured blossoms, was also finely in flower; and *D. senile* is a very curious miniature kind, with short stems densely covered with whitish hairs. W.

NOTES OF THE WEEK.

Fine English Asparagus.—Mr. Harwood, of Colchester, took the first prize for Asparagus at the Colchester and Essex Horticultural Society's show last week with one of the finest specimens of English Asparagus which we have yet seen. We are persuaded that in a very few years specimens as fine as any sent from abroad will be grown by the same market gardener. It is blanchet to about the same degree as the best French, the tip slightly green and an inch or two pinkish, but not so much as the Dutch Asparagus.

Cassiope fastigiata.—This rare and beautiful Ericaceous plant is now bearing a profusion of blossoms in one of the open borders at Kew, where it has been quite unprotected during the past winter. It grows to about 1 ft. high, and has small scale-like leaves densely arranged on the stem in a quadrangular manner, similar to *Andromeda tetragona*. The blossoms are small and bell-shaped, of a pure waxy whiteness, with a delicate pink eye, and hang gracefully from the upper part of the stems. A moist peaty soil and partial shade apparently suit it admirably.

Tulipa stellata.—A bed of this rare and beautiful Tulip is now very showy in Mr. Bull's nursery. It is somewhat similar to the European *T. Clusiana*, but is superior to that kind, inasmuch as the blossoms are larger and pure white, with a faint dash of yellow at the inner base and a delicate bluish tinge on the outside. It is a native of the Western Himalayas, where it is found at great elevations; hence it is hardy in our climate.

Leelia elegans alba.—A magnificent cluster of this lovely Orchid has been sent to us from Sir Trevor Lawrence's rich collection at Burford Lodge, Dorking. Its blossoms are large and the colours well defined, especially on the lip, the bright amethyst tint of which forms a striking contrast to the pure white of the other parts. Altogether it is a decided improvement on the type, and the cluster of flowers sent are admirable examples of skilful cultivation.

Lilium Hansonii in Pots.—This rare and handsome Lily succeeds admirably when grown in pots, a condition in which we saw it a few days ago in Mr. Bull's nursery, in which it was producing its pretty orange and chocolate coloured flowers very freely, bearing as many as fourteen on two stems in one pot. It grows from 2 ft. to 3 ft. high, and the leaves are arranged in whorls at wide intervals on the stem.

Spring Flowers at Wantage.—Mr. Caudwell, of Wantage, a place celebrated for Primulas, Pansies, Polyanthus, and similar plants, has sent us some beautiful semi-double Cowslips, dwarf in habit and profuse flowerers: a very dark Polyanthus for spring bedding; also a Polyanthus named King Alfred, a finely-laced variety, and two good Daisies, white and red, the last prettily quilled.

Herbaceous Calceolarias at Langport.—There is now a fine show of these in Messrs. Kelway's nursery at Langport. It consists of about a thousand plants, blooms of some of which have been sent to us, and, judging from their size and striking colours, the display must be a very effective one.

Cornus canadensis.—Flowering plants of this pretty and now somewhat rare miniature shrub we saw a few days ago in Messrs. Jackson & Son's nursery at Kingston. It grows from 4 in. to 6 in. high, and has the upper leaves of the stem in whorls generally from four to six in number. The flowers are small and purplish, surrounded by a white involucre nearly 1 in. across, which is the most conspicuous part. It delights in moist soil, and makes an interesting bog plant, or it may be planted in the lower parts of the rock garden.

Rubus deliciosus.—One of the prettiest shrubs at present in flower at Kew is this fine Californian Bramble. It forms a compact bush a yard or more high, and for a considerable time at this season covered with a profusion of pure white blossoms, which are 2 in. or more across, succeeded by red fruits, which, by the way, are not very delicious.

Cattleya MacMorelandi.—This lovely and rare Orchid is now in flower in Messrs. Veitch & Sons' nursery at Chelsea. In habit and general aspect it is similar to *C. Mossii*, but the flowers which are rather larger than those of the ordinary varieties of *C. Mossii*, have the segments pure white, with the exception of a delicate bluish tinge on the two lateral sepals. The lip is very shallow and much crisped at the margins, with two conspicuous deep orange blotches, and a faint purplish-violet tinge at the base. Scarcely less beautiful, and quite as rare, is *C. Wagneri*, which is also in flower at Chelsea. The blossoms are large and pure white, with nothing to mar their chaste beauty except a faint dash of lemon tint at the tip of the lip.

Green Trees in London.—It is charming just now, after the harsh spring and winter, to see the beauty of the budding trees in many parts of Central and West-Central London. Such beauty should encourage people to form gardens and to plant trees in such places, for the success of those already planted shows, as far as deciduous trees are concerned, that the beauty of spring buds or summer foliage is as evident in London as in the country, and far more welcome.—V.

Iris tenax.—We noticed the true form of this fine North American Iris in flower in the Kew collection, and also at Mr. Ware's nursery, at Tottenham. Its foliage is narrow and very tough, the bases of the leaves having a pinkish tint. The flowers, which are large, are borne singly, and have oblong beardless falls of pale lavender hue, with a conspicuous spot almost white, the standards being narrow and of the same colour. It is a handsome border flower, and one which succeeds best in rather moist localities.

Alpine Phloxes at Tottenham.—These beautiful rock-plant varieties of *P. subulata* are now in full beauty in Mr. Ware's nursery at Tottenham, and nothing can well exceed the brilliant effect which they produce when seen in masses. They vary in colour almost as much as the numerous forms of *P. Drummondii*, the flowers varying from pure white to a deep violet-purple and clear rose, with every intermediate shade. It is one of the best plants with which we are acquainted for covering exposed places on rockeries, as it grows so rapidly and flowers so profusely.

Haberlea rhodopensis.—This rare Alpine geraneaceous plant, of which we gave an illustration last week, will shortly be in flower in Mr. Ware's nursery at Tottenham. It was planted on the rockery a few years ago, where it has remained unharmed, though quite unprotected. It has not, however, shown signs of flowering previously.

—No one can entertain any doubts as to the complete hardness of this plant. I have had it in the rockwork without protection for two years, but it has not yet flowered.—H. N. ELLACOMBE, *Bitton Vicarage*.

Cacti in Flower at Hammersmith.—Mr. Peacock's collection is now enlivened by the following beautiful and in most cases rare species, viz., *Echinocactus mammosus*, a kind with pretty golden blossoms, 2½ in. across, borne on the apex on a cushion-like plant beset with strong spines; *Camillaria Schiediana*, with numerous magenta-coloured fruits, in form and size much resembling those of the common *Barberry*, thickly studded on the conical stems, and enveloped in white star-shaped hairs. Similar to this is *M. stellaris*, the hairs of which are, however, browner in colour. *M. Fosteri* is another pretty kind with magenta-coloured blossoms. The most beautiful which we saw was *M. Burgessii*, which was about 4 in. high, and which had a thick rounded stem the surface of which was studded with about two dozen deep magenta-tinted blossoms, each nearly as large as a shilling, which rendered it very effective. These are but a few of the many choice succulent plants that afford interest to the plant lover in this collection.

The True Meconopsis simplicifolia is now in flower in the York Nurseries. It has had the credit of being one of the finest of Himalayan Alpines, and certainly is a striking and beautiful plant. Its flowers measure 3 in. across, and are borne solitarily on stalks 1½ ft. to 2 ft. high; they are of a deep rich blue, shaded towards the margins of the inner petals with rosy-purple, colours with which a mass of deep golden anthers in the centre contrasts grandly. The leaves, as the name implies, are very nearly, and sometimes quite, entire. They measure from 4 in. to 6 in. in length, and are lanceolate and hairy. This species is deciduous and truly perennial. The allied *M. aculeata*, another Himalayan species, also promises to make a fine show in the same nurseries shortly. It has branching stems, and forms a pyramidal mass of large purplish-blue flowers from 1½ ft. to 2½ ft. high. Its leaves are deeply lobed and rough, with coarse hairs. This, too, is deciduous and perennial. Both are quite hardy.—P.

Orchids at Chelsea.—A few days ago we noticed amongst many other Orchids in flower at Messrs. Veitch's the following beautiful kinds, viz., the *Colax jugosa*, with broad, handsome foliage and wax-like blossoms, the outer sepals being white and the inner prettily mottled with deep purple. Amongst the *Dendrobiums*, the most desirable in flower were—*D. Bensonii*, a splendid species, remarkably free flowering, with yellow and white blossoms, with two conspicuous brownish-black blotches at the base of the lip; *D. infundibulum* and *D. formosum* are somewhat similar, their large flowers of ivory whiteness rendering them very attractive. For suspended baskets, few of the late-flowering kinds are better adapted than *D. crystallinum*, the large orange lip and magenta-tipped sepals of which are very showy and last a long time in perfection. *D. tortile*, though by no means a novelty, is not often met:

with, though, on account of its delicately-tinted flowers and curious spirally twisted sepals, it is very desirable. The display of *Odontoglossum Alexandræ* is remarkably fine; the varieties are numerous, both as regards size of flower and colouring, and all are well grown, many long arching flower-stems bearing from eight to sixteen blossoms. *O. cirrhosum*, too, is very beautiful, and a dangerous rival to the preceding, particularly in the case of some of the finest varieties, of which there are several here. Amongst Orchids noteworthy as curiosities, none are so interesting as the exquisite little *Restrepia antennifera*, the blossoms of which have the lower sepal joined into a boat-shaped form, the others attenuated into antennae-like processes, all beautifully spotted with reddish-chocolate on a yellowish ground. The flowers of *Masdevallia Peristeria* form a striking contrast to those of its showy congeners, as they have nothing to recommend them but singular form and strange but dull markings.

Rose-coloured Solomon's Seal (*Polygonatum roseum*).—We lately saw flowering examples of this choice hardy plant at Kew, and also at Mr. Ware's nursery at Tottenham. The specimens in question were about 1 ft. high, though the plant is said to grow from 2 ft. to 3 ft. high in a wild state. The stems are quite erect, with the leaves, which are lance-shaped and glaucous, arranged in whorls. The blossoms are tubular, and about $\frac{3}{4}$ in. long, borne in pairs from the axils of the leaves on short, slender stalks; hence the flowers are drooping. The colour being of a soft rose tint, the flowers have a pretty effect set off by the rich glaucous hue of the foliage. It inhabits various regions in Central Siberia, and though it has been introduced for some considerable time, it is at present very rare in collections.

Masdevallia Backhousiana.—This singular and highly interesting novelty, which was disposed of at Stevens' the other day, is now flowering in Mr. Peacock's collection at Hammersmith. As we have previously remarked, it is allied to *M. Chimera*, but it is considered by Professor Reichenbach to differ from that kind. The flowers are produced singly, and the three segments are from $\frac{3}{4}$ in. to 4 in. across, each having tail-like attenuations from $\frac{1}{4}$ in. to $\frac{3}{4}$ in. in length. The ground colour is pale yellow, thickly spotted with reddish-chocolate, and covered on the inner surface with numerous short hairs. The lip is small, and forms a whitish, pocket-like process in the centre.

Pleione Hookeriana.—Several pots of this charming Alpine Orchid now in flower forms a conspicuous feature in the Orchid houses at Mr. Peacock's garden at Hammersmith. It is, perhaps, the smallest of all the cultivated kinds, growing not more than 3 in. high, and bearing numerous blossoms, which spring from amidst short, ovate leaves. The colour is delicate pink and white, the lip being of a darker hue, and the pencillings of a lemon tint. It is one of the most desirable kinds for growing in a cool house, conditions under which it thrives admirably. It is found at considerable elevations in the Eastern Himalayas.

Hibbertia Reedi.—This charming little Australian plant is now seldom met with, yet it is one of the prettiest ornaments which a greenhouse could possess during spring, when it is literally covered with small golden blossoms, which are very effective mixed with those of other plants. We saw it a few days since in Messrs. Lee & Son's nursery at Hammersmith, where many of the now little-known Australian plants receive attention. In addition to this, we saw a variety of *Hedera multiflora* with flowers the markings of which were of a deep blood-red, being the darkest-coloured form with which we have yet met.

Hesperochiron pumilus.—This rare hardy plant is now in flower on the rockery in Mr. Ware's nursery at Tottenham. It is stemless, dwarf in growth, and has numerous oblong leaves borne on slender stalks, forming a rosette tuft. The flowers are produced singly on slender stems from the axils of the leaves, erect, bell-shaped, measuring nearly $\frac{1}{2}$ in. across, and are white, varying to a purplish tinge. It grows in marshy ground, and in other damp places in the Rocky Mountains of Northern Utah, &c. It belongs to the same family as the *Nemophila*, and is as yet scarcely known amongst cultivators.—W. G.

Masdevallia tovarensis.—As an instance of the free-flowering habit of this charming cool-house Orchid, we notice in the last number of "*L'illustration Horticole*" that a plant in the garden of M. de Rothschild, at Ferrières, had 137 blossoms expanded on it at one time.—W.

Succulent Plant Catalogue.—Mr. Peacock, Sudbury House, Hammersmith, has printed a catalogue of his succulent plants, consisting of the names of the plants according to their current nomenclature. The result is a neat little brochure invaluable for reference, more especially if the names had been accurately spelt, which in many cases they are not. Mr. Peacock has resolved to distribute 5000 copies of it amongst growers and collectors of

succulents. Those who wish for it, therefore, have only to send to him a suitable wrapper directed and stamped.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JUNE 2.

THIS, the Whit Monday flower show, notwithstanding a downpour of rain during the whole day, was visited by nearly 9000 persons. The large tent was well filled with plants, but this was owing chiefly to the liberality of exhibitors at the last meeting, many of whom allowed their groups to remain, which added much to the attractiveness of the show. These included Mr. Jackson's Clematises, Roses from the Slough, Cheslunt, and Chelsea Nurseries, the miscellaneous collections from Mr. B. S. Williams, Messrs. Cutbush & Sons, Osborn & Son, Laing & Co., Boller, and others, besides several groups of Ferns, fine-foliaged plants, &c., from private gardens. The competitive classes were not so well filled as might have been expected, especially those which contended for the general prizes, and the exhibits, too, were neither numerous nor noteworthy. The prizes for groups of decorative plants arranged for effect were awarded to Messrs. Wills, Hooper & Co., Aldous, in the order in which they are mentioned. The collections of plants in flower were, on the whole, very well grown, especially *Fuchsias* and *Pelargoniums*. A group of Harrison's Musk, shown by Messrs. Reeves, was deservedly much admired, and gained the first prize.

MANCHESTER ROYAL BOTANICAL AND HORTICULTURAL SOCIETY.

MAY 30 TO JUNE 6.

NOTWITHSTANDING the sunless spring which we have had, the display made on this occasion, taking it collectively, was above the average of what these annual Whitsuntide exhibitions held here usually are, and which are deservedly most successful, combining, as they do, an assemblage of every description of plants, exotic and hardy, that can at this season of the year be shown in a condition to fairly represent their respective kinds. Every available foot of space in the permanent exhibition building, the annex adjoining, and also the large tent, were filled as full as they could hold. The evergreen trees and shrubs, as well as kindred subjects were grouped outside, and added much to the interest and general effect of the exhibition.

In the amateur's class of twenty stove and greenhouse plants, half flowering and half fine-leaved subjects, there were three exhibitors, who collectively staged such a bank of fine specimens as have rarely before been brought together. The two best collections, shown by Mr. Tudgey, gardener to J. F. G. Williams, Esq., Worcester, and Mr. Hamlett, gardener to E. Pilgrim, Esq., Cheltenham, were so nearly matched that the judges awarded first prizes to both, and well they deserved it. In Mr. Tudgey's group there was an unusually good *Anthurium Scherzerianum* not less than 4½ ft. through and as much in height, bearing some sixty fully developed flowers large in size and bright in colour; it is much the largest example we have seen. The fine spring-blooming *Heaths*, *Victoria* and *ventricosa* *magnifica*, were large in size and profusely flowered. Three *Palms* in the same group, viz., *Geonoma gracilis*, *Stevensonia grandifolia*, and *Pritchardia pacifica*, were very elegant, yet massive. Mr. Hamlett had a wonderfully fine *Cordylina indivisa*, the largest of which were extremely stout and strong; a fine new orange-coloured seedling *Ixora*, named *Pilgrimi*; several well flowered *Azaleas*, including the glowing purple *Duc de Nassau*, still one of the best; an immense *Encephalartos villosus*, and a couple of large and vigorous *Gleichenias*, *G. Splendens* and *G. rupestris*.

In the corresponding class for nurserymen there were also three exhibitors, among which Mr. Cypher of Cheltenham, and Messrs. Cole, of Manchester, had a close run, but the first prize was awarded to the former. This collection contained the finest-flowered yellow *Carendish Heath* with which we have met; it was literally covered with bloom from top to bottom, so much so as to scarcely admit of its leaves being seen; an equally well-bloomed *Stephanotis floribunda*, and the now seldom-seen *Pimelea spectabilis* rubra, which the best form of this distinct and handsome plant, were also shown in this collection. In Messrs. Cole's group was a profusely-flowered blue *Statice profusa*, 5 ft. in diameter, and a very meritorious *Ixora coccinea*, covered with bright scarlet flowers, which, when well managed, as this was, is the finest of all the *Ixoras*. Messrs. Caldwell, of Knutsford, Cheshire, had an effective exhibition, in which were beautiful examples of the elegant *Davallia Mooreana* and

Gleichenia dichotoma, both of which rank amongst the most distinct and beautiful of Ferns. The six collections competing in these classes were such as to really make an exhibition in themselves, and at once exemplified the superiority of the effect produced by mixed groups of blooming and fine-leaved plants over an arrangement in which the flowering and the ornamental-foliaged subjects are shown separately.

Orchids, as usual at Manchester, were present in much greater numbers, and the plants individually larger than those seen at other shows, although on this occasion some collections were absent. In the amateurs' division for fifteen plants Mr. Bolt, gardener to W. Turner, Esq., was first. Most notable amongst his plants were an exceedingly well-grown *Odontoglossum vexillarium*, bearing sixteen large spikes of flower; O. Roezli, with eighteen flowers; O. cirrhosum, equally fine; *Saccolabium Turneri*, one of the forms of *S. guttatum*, unsurpassed if equalled by any of the others; it bore four charming drooping racemes, the largest of which was over 20 in. long, the spotting and colour of the labellum deeper than usual; associated with this were also *S. guttatum*, with seven spikes; *Aerides Fieldingi*, bearing five spikes; *Masdevallia Lindenii*, and *Lælia purpurata*, splendidly bloomed. Mr. Swan, gardener to W. Leech, Esq., who was second, had in a very good group a very large and finely-bloomed *Dendrobium thyrsiflorum*, with fourteen of its lemon and white-coloured drooping racemes. For nine Orchids Mr. Osman, gardener to E. B. Dodgson, Esq., received the first award; amongst them were the glowing magenta *Masdevallia Harryana*, with large flowers; *Dendrobium Schröderi*, and *D. Devonianum*.

Groups of fine-leaved Plants were well and largely shown, and had an excellent effect, serving as a background for the Orchids and other smaller growing flowering plants. They consisted of the usual kinds of Palms, Cycads, Crotons, Tree and other Ferns, &c., and, as arranged on this occasion, they happily toned down the glow of colour produced by flowering plants without making the whole too sombre, a result of not unfrequent occurrence since large fine-leaved subjects have been so much used, both at exhibitions and for general purposes and decoration. The new permanent iron canvas-covered annex adjoining the exhibition house, 330 ft. long and 72 ft. wide, presented a beautiful appearance looked at collectively, and the plants individually were generally well grown. Conspicuous amongst them were Mr. C. Turner's large and magnificently bloomed Roses, which here had no rivals; he showed in both the classes for 12 and 20. The most remarkable amongst them were large bushes of the well-known pale rose-coloured Charles Lawson, Céline Forestier (pale lemon colour), Miss Ingram, Paul Verdier, Beauty of Waltham, Edouard Morren, Madame Thérèse Levet, and the ever-lovely La France.

Azaleas were well shown by Messrs. Cole, whose plants were beautifully flowered and nearly untrained, their branches being allowed to hang in almost their natural positions.

Exotic Ferns.—Of these a well-grown group was contributed by Mr. Lingard, gardener to H. Samson, Esq., in which were large examples of *Gleichenia Spelunca*, G. Mendelli, and G. flabellata; the latter one of the most distinct.

Miscellaneous Subjects.—Messrs. J. Waterer & Sons, of Bagshot, occupied all the end of the annex with *Rhododendrons*, to which the Society's gold medal was awarded. In the class of twenty miscellaneous plants in or out of flower, Mr. Smith, gardener to J. Rylands, Esq., stood first, having amongst others a very large spreading example of the fine Tree Fern (*Cibotium regale*). Prizes were offered for *Sarracenias*, *Nepenthes*, *Droseras*, and kindred plants, and shown in that way they were very effective. A group shown by Mr. Bruce, gardener to J. Fildes, Esq., contained unusually well-grown *Sarracenias*, consisting of *S. Drummondii* alba, *S. Drummondii* rubra, *S. variolaris*, *S. psittacina*, *S. purpurea*, *S. rubra*, and four forms of *S. flava*; also *Darlingtonia californica*, numerous *Droseras*, and *Dionea muscipula*. Mr. Anderson, Meadowbank, Glasgow, received the Society's gold medal for a beautiful exhibition of *Amaryllides*. Messrs. R. P. Ker & Sons, Liverpool, won the Society's gold medal for a hundred miscellaneous plants effectively arranged. Messrs. J. Dickson & Sons, Chester, had a fine collection of eighty Alpine and herbaceous plants, for which a gold medal was awarded. One of the most interesting exhibits present was Messrs. Standish & Co.'s Japanese hardy plants, consisting of some 600, representing eighty-five species or distinct varieties; to this a gold medal was also awarded. Messrs. Waterer likewise received a similar medal for a beautiful collection of twenty-five varieties of Holly, and another for ten hardy evergreen trees and shrubs. Messrs. Osborn & Sons showed a select group, consisting of this class of plant, not over large, but in perfect condition. Mr. B. S. Williams was awarded a gold medal for twelve new and rare plants. The same exhibitor also had a large and varied collection of plants, not for competition, as had likewise Messrs. Osborn & Sons, from whom came some finely-flowered large baskets full of the lovely blue *Gentiana acaulis*, much fuller of bloom than it is often met with.

Messrs. R. P. Ker & Sons had likewise a very interesting group of plants of this description.

Fruit was quite as abundant as the dull character of the season would have led one to expect. Mr. Miles, gardener to Lord Carington, was first, with a very good collection, in which were Black Hamburg and Muscat of Alexandria Grapes; Black Circassian, and Governor Wood Cherries; beautifully finished very fine James Veitch Strawberries; Elruge Nectarines; Brown Turkey Figs; Cox's Golden Gem Melon, and a Pine. Mr. Jamieson, gardener to the Earl of Crawford and Balcarrais, was first for Black Hamburg Grapes, finely finished, black, and well covered with bloom. In the class for white Grapes, Mr. Bannerman, gardener to Lord Bagot, took the first prize with a very good Buckland Sweetwater. Mr. Upjohn, gardener to the Earl of Ellesmere, was first for Strawberries in pots.

A list of prizes will be found in our advertisement columns.

PLATE CLXXXIII.

LILIUM PARKMANNI.

Drawn by NOEL HUMPHREYS.

THIS remarkable Lily was raised by Mr. Parkman, President of the Massachusetts Horticultural Society. It is a hybrid between *L. auratum* and a deep-coloured variety of *L. speciosum*. The latter was the female parent. Fertilisation, Mr. Parkman states, took place readily, and the young bulbs were planted in the open ground for the first time in the spring of 1869. There were about fifty of them. Several, as they grew, showed the peculiar spotted stem of the male parent, but when they set flower-buds, as nearly all of them did in the same season, the features of *L. auratum* could be distinguished only in one of them. The rest, in bud and flower, appeared to be merely *L. speciosum*, quite unaffected by the pollen of the male parent. The one alluded to was a remarkable exception. The flower opened ten days earlier than any of the rest; it had the fragrance of *auratum*, and resembled it also in form. This first flower measured 9½ in. from tip to tip of the petals. In the following year there were several flowers, of which the largest measured 1½ in. This hybrid, Mr. Parkman reports, was the most successful result of a great number of experiments tried by him in the cross-fertilisation of Lilies. This genus is certainly remarkable in the tenacity with which it preserves the characteristics of the female parent and resists the influence of the male. Thus he impregnated *L. longitorum* and *L. Takesima* with the pollen of *L. auratum*, *L. speciosum*, and six or eight other Lilies, the anthers of the fertilised flowers being carefully removed before they ripened. *L. Takesima* bore seed in abundance, but the resulting plant did not differ perceptibly from its female parent, showing no feature of the male. He removed its anthers and fertilised it again with *auratum* and *speciosum*, thinking that the influence of the male might appear in the second generation if not in the first, but this double fertilisation produced no effect. The same result followed a similar experiment with *L. canadense* and *L. superbum*. In this case also the flower resulting from the first experiment was again fertilised. The result was a very scanty crop of seed, but this seed produced a plant in which no sign of the male influence was visible. *L. Parkmanni*, as will be seen, is a noble Lily, large in size and strikingly bright in colour. It succeeds well in a pot, but Mr. Anthony Waterer, from whose establishment, at Knapp Hill, the flower was obtained from which our plate was prepared, informs us that it grows freely with him planted out in company with *L. speciosum*.

Dates of Rose Shows.—"Delta," who objects to the alteration of the dates of Rose shows, has doubtless since then found that two fine days do not make a spring, and also that outdoor Roses have so far made but slow progress. Looking at the general effects upon vegetation produced by the late cold spring, it is impossible to doubt that Roses must be backward. In making such important changes, depend upon it the authorities of the shows in question have not done so without good reason. "Delta" says, "changes in shows are sure to be charged as brought about in someone's interest." Certainly in the present case it is so, but it is in the interest of both growers and the public. The laws of the Medes and Persians may have been unalterable, but the dates of shows are not; and when the season is a month later than usual, show authorities may well alter their shows to suit the season.—A. D.

Royal Oxfordshire Horticultural Society's Show, June 17.—It may interest some to know that Messrs. Webb & Sons, Worsley, Stourbridge, give special prizes at this exhibition for the best collections of vegetables, consisting of eight distinct varieties, and including Webb's Improved Ashleaf Potato and Webb's Perfection Pea. 1st prize, 21s.; 2nd prize, 14s.; 3rd prize, 7s.

of the pots they occupy, which permits of their making growth at the same time the flowers are expanding which will bloom in succession, to assist which manure water should be given once a week. Plants that have had their points pinched out to induce late flowering will also be benefited by manure water, and care should be taken to see that they are quite clear from aphides before the blooms expand, otherwise if it becomes necessary to fumigate them after they open, it will cause most of the petals to drop.—T. BAINES.

Hardy Fruit.

The most pressing requirement in this department now is the extermination of aphides, for, in spite of every precaution, black aphid is almost certain to attack Cherries, and sometimes Peaches and Plums; and if the trees be not dressed as soon as they are attacked, the aphid increases with such rapidity, that remedial appliances have to be so strong, that injurious effects are apt to happen. Our usual remedy is soap-suds, used just as they come from the laundry, but if the trees be badly infested Tobacco liquor is added, and in a day or two afterwards they are well washed with clean soft water, applied with some little amount of force by means of the syringe or garden engine. Another important operation now demanding attention is thinning the fruit, but to what extent it is difficult to say, as so much depends on the variety, health, vigour, &c., of the trees. Each one must therefore decide for himself as to the quantity of fruit which each tree is able to perfect without injuriously affecting the next year's crop, for it should ever be a maxim that two moderate crops are preferable to one heavy one. The surplus fruit of Apricots with us were picked off a week ago, those removed being the smallest and worst, placed such as those behind or between the branches. Peaches have set in clusters, and are now being thinned; and so are Pears on south and west walls; the thinning of standards and pyramidal trees will follow a fortnight hence, and at the same time the most vigorous shoots will be stopped, and the weaker growths a few days later. In thinning Pears bear in mind the variety; for instance, twice the number of fruit may be left on a tree of Winter Nela as on that of Duchesse d'Angoulême, for the obvious reason that the latter fruit is double the size of that of the former. Again, as to Peaches and Nectarines, one large fruit is infinitely better than two small ones. If the trees have received their final disbudbing, the permanent growths may now be laid or tied in in the case of walls not wired; a few Hazel twigs, placed in a horizontal position in front of each shoot, and fixed at the ends in the old branches, answer all the purposes of nails and shreds, and the work is done more expeditiously. Stop at the first joint all the sub-laterals that are being made by next year's fruiting wood, and pinch out the points of any shoots that are growing too robustly. This is the season when cordon-trained trees require most attention, which, however, merely consists in constantly keeping the growths well stopped back, an operation which induces fruitfulness, but which, at the same time, in some measure cripples the trees. The latter, therefore, must be kept in health and vigour by means of frequent manurial dressings. These are best supplied in the shape of surface mulchings of well-rotted manure, which should be continued during the whole of the growing season. The great merit of the cordon system is the large variety of fruit that can be had from a comparatively limited space; therefore, in the case of small gardens, cordons are worthy of adoption if for no other reason than this. A large tree of Williams' Bon Chrétien Pear, that may produce bushels of fruit that will not keep, is, to an amateur, of no more value than a tree that produces a couple of dozen fruit, and as the cordon system admits of at least twelve kinds being grown in the space of one large, fan-trained tree, a long succession of fruit may be had in lieu of the fortnight during which Williams' Bon Chrétien remains good; if the fruit be grown for market, that, of course, is another matter, but even then a greater variety would be desirable. Red and White Currants are exceptionally well-fruited, and we are now cutting, or rather pinching, off some of the useless spray which overshadows the fruit; the main shoots will not be cut till after the fruit is gathered, as these form supports for the nets, which we are obliged to use to keep off birds. Gooseberries are being similarly treated. Summer stopping of these is not generally practised, but it ought to be, considering that such stopping ensures handsomer and more prolific bushes.—W. W.

Extracts from my Diary—June 9 to June 14.

FLOWERS.—Potting Eupatoriums and Bonvardias raised from cuttings; also Mignonette and Double Petunias. Propagating Poinsettias. Tying in young shoots of Stephanotis and Allamanda. FRUIT.—Commencing to thin Grapes in late Vinery (Black Alicante). Going over Black Hamburgh Grapes for exhibition, and cutting out all inside and crowded berries. Watering late Vinery border with manure water. Potting Garibaldi Strawberry for autumn fruiting. Layering a few early runners of Keen's Seedling and Perpetual Pine Strawberries for early forcing. Trenching ground for Strawberries.

Mulching Peach borders with decayed manure. Tying in young shoots of Peaches, &c.; dusting Peaches outside with Tobacco powder to kill green-fly, &c. VEGETABLES.—Tying and stopping Cucumbers. Hoeing between all growing crops, and staking Scarlet Runners. Digging out Celery trenches. Planting Veitch's Self-Protecting Broccoli. Weeding and thinning out crops of Parsnips, Beet, and Carrots. Sowing a batch of Rosette Colewort, Little Pixie Cabbage, Green Cos, and Wheeler's Tom Thumb Lettuce. Thinning out beds of Carrots, Onions, Beets, and Parsnips. Clearing ground of Spinach. Planting out more Lettuces between Celery trenches. Hoeing and cleaning Asparagus beds, and sowing Mustard and Cress.—R. GILBERT, *Burghley*.

TREES, SHRUBS, AND WOODLANDS.

NEW ZEALAND FORESTS.

THE New Zealand forest is entirely evergreen, and though the return of spring is not visible in a fresh outburst of foliage, which makes the woodlands of the old country so attractive, yet there is compensation in the landscape being spared from the desolating appearance of leafless trees. Many of those plants which adorn our conservatories with continual freshness are natives of this forest. For instance, the Tree Fern *Dicksonia antarctica* is well known for its majestic appearance, but it should certainly be seen in this its natural habitat, with stems 20 ft. high, crowned by fronds from 8 ft. to 10 ft. long. To stand at the side of a chasm and look down its rugged sides clothed with Blechnum and Mosses, a gushing stream sparkling at the base, and one of these giant Ferns filling up the centre, is but a sample of the many natural Feries which the traveller comes across. Another exile known to most lovers of Palms is *Areca sapida*. It soon overtops the Tree Ferns, while the different shades of green make a pleasing contrast. In spring it throws out bunches of red berries, which are much prized by the natives, while the leaves are used by many settlers for thatching purposes. In its habit of growth it seems to shun all exposure, and seeks the shelter of other trees. Often it is found in places completely guarded against both sun and wind. We have a species of Cabbage tree, which from its hardy habit would do well for "sub-tropical gardening." In leaf it is much like a *Dracæna*, and when seen at a distance looks very like a plume of feathers. For greenhouse decoration in winter it would be a pleasing object. Another denizen of the forest here is *Dacrydium cupressinum*, a plant which has not received the attention which it deserves. It has been in cultivation more or less for thirty years, and having been numbered with the Juniper family, may in some collections be found labelled *Juniperus* *clata*. The brightness of its evergreen foliage, which retains vigour and freshness throughout the entire year, with innumerable waving branches bending with feathery lightness to the most gentle breezes, including a pleasant symmetry of form, all tend to give it rank amongst the rare and beautiful, and make it a most desirable plant for greenhouse culture.

We may now notice one or two of the timber trees which constitute the wealth of the New Zealand forest. The foremost of these is known to collectors of hard woods as *Dammara australis*. Leaving out some of our British Oaks of historic fame, it would be almost impossible to find a more stately tree. It is common to meet with it in the forest of the North Island, rising to a height of 150 ft., and measuring 30 ft. in circumference at the base. The wood is very inflammable, from the amount of resin contained in it; and this no doubt accounts for vast extents of such forest having been accidentally burnt. It exudes a valuable gum, which has become an important article of commerce. For shipbuilding it is considered equal to Oak, and large quantities are annually exported for that purpose. Another timber tree of colonial reputation is *Podocarpus Totara*. In foliage it is somewhat sombre; the wood is so close in the grain as to be termed "iron wood" by the natives, and is of course very durable. As indicative of the wide domain of some of the Natural Orders, we may mention that the *Verbenæ* has a representative here, which ranks amongst the finest timber trees which the colony possesses, viz., *Vitex littoralis*. After the first few years of growth it begins to assume its proper form, which ever after marks it as one of the handsomest trees of the forest; and for the construction of wharfs and bridges, and every variety of work where it is necessary that wood should be considered invaluable.

The New Zealand forest cannot be said to be rich in floral productions. There are, however, some which deserve notice. Foremost amongst these, for peculiarity of growth and gaiety of flower, ranks the *Kata* (*Metrosideros lucida*). It commences to entwine round other trees in the form of a very slim climber, but its growth is so rapid that it quickly encircles the whole tree. With every fold it tightens its grasp until all vitality is entirely crushed out of the

trunk round which it clings for support. Another member of the same family, *Metrosideros tomentosa*, makes the forest somewhat gay during the months of December and January. Its flowers, which are scarlet, are arranged in terminal cymes. British residents have honoured it with the name of "Christmas tree." Another floral attraction in the forest is *Clematis Nova Zealandica*. It provides itself with a natural trellis-work by entwining the rugged stem, and then hanging down from the branches in long festoons. The flowers are pure white, and produced in rich profusion; and being a spring flower, it is to the natives a floral almanac, telling them when to plant their much-prized Kumara or Sweet Potato.—"The Gardener."

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Hardiness of Shrubs at Coombe Wood.—It may be of interest to state that, in the elevated portions of Messrs. Veitch & Son's Nursery, several shrubs which in other places—at Kew, for instance—have been severely injured, or even killed, have suffered comparatively little at Coombe Wood. Amongst these are the Chilean *Azara microphylla*, *Berberis Darwinii*, *Grevillea rosmarinifolia*, not injured in the least, and thriving luxuriantly; *Xanthoceras sorbifolia*, uninjured, and about to flower; and *Magnolia Campbelli*, a Himalayan species, breaking freely; the Golden Chestnut (*Castanea chrysophylla*) is, however, severely hurt; *Quercus Buergeri* (a handsome Japanese Oak), *Viburnum Awafukii*, *Raphiolepis ovata*, *Olearia Haastii*, *Osmanthus myrtifolius*, and the ornamental Japanese Grass (*Eulalia japonica variegata*) are quite uninjured and thriving vigorously.—W. G.

Hardiness of the Indian Azalea.—Amongst the trees and shrubs which have passed through the winter unharmed, none in this district are more conspicuous than the varieties of *Azalea indica*; of these several plants in large pots were placed out-of-doors in a high exposed position about this time last year, and from that time until now they have neither been removed nor protected, and in a few days they will be masses of bloom—as fine, in fact, as any that could be grown indoors. Last year when overhauling our *Azaleas* two or three which were nearly killed by standing too long in a dark place were thrown away; one of our labourers picked them up and planted them in his little front garden; there they made good growth, and they are now beautifully in bloom. In another place not far from here there is another fine plant quite established out-of-doors and doing well; therefore it may be fairly inferred, I think, that Indian *Azaleas* might safely be made to adorn our lawns and shrubberies, and I can assure those who have never seen them at their best out-of-doors that very few shrubs surpass them in beauty.—CAMERIAN.

Xanthoceras sorbifolia.—This has been in flower here for nearly a fortnight, and I am very much disappointed with it. Perhaps, however, the frosts and winds of May have disfigured it, and that in a better season it would be more attractive.—H. N. ELLA-COMBE, *Bliton Vicarage*.

ROSES.

Outdoor Roses.—Like all plants that make a large growth annually, Roses, either mixed with other plants or by themselves, exhaust the soil in beds and borders devoted to them rapidly; but little difficulty exists in supplying them with all they require in this respect, as liberal dressings can be forked in after they are pruned, and mulching with manure through the summer months can also be resorted to. Where the land is at all of a light description, this covering with rotten manure is of the greatest possible use, for not only are the plants invigorated thereby, but it protects the best roots, which are those that lie nearest the top, from the scorching power of the sun, and it also very much reduces the loss of moisture from the soil by evaporation, consequently it is often better to apply a portion of the manure given to Roses in this way than dig the whole into the ground. Where mulching has not been previously carried out, I should recommend it to be at once applied; but in private places where it is frequently most needed, when the beds hold a prominent position, the manure used needs to be of a character such as not to form an eyesore, that is, it should not contain much strawy matter, and ought to be so far rotten that it can at the time of putting it on be reduced to a fine condition, in which case it will have no more objectionable appearance than a surface covered with tan. An excellent and far from unsightly material for mulching Roses, where obtainable, is spent Hops, laid on about 1 in. thick. There is seldom much difficulty in getting these near large towns, and a cartload will go a long way. Although they not possess enriching properties more than ordinary vegetable matter, they keep the ground cool and the

roots from being parched up by the action of the sun. In private gardens, Roses are planted in so many positions and so many ways as almost to preclude the possibility of giving them the manual sustenance which they require. This is especially the case with standards when planted on Grass in rows by the sides of walks and in similar situations. I have always held that this is the most objectionable way in which Roses can be grown, as from the difficulty above stated they often get into such an impoverished condition as to be anything but ornamental. One way of meeting this is in winter to remove the turf for some feet round the roots and add new soil and manure, afterwards replacing the turf, but the objection to this is that it makes the Grass grow round the trees at such a rate, as to require mowing twice as often as the adjoining surface, and from its extra greenness gives the lawn a patchy appearance, but where Roses are thus grown it is necessary to do something, in order to assist the exhausted soil. This may be accomplished now with marked effect, by giving liberal soakings of manure water to the circular spaces that are usually left unfurrowed round each tree, filling these up with the liquid several times, by which means it will not only settle straight down, but will spread out towards the extremities of the roots under the Grass. If given before growth commences, the first after blooming is over, its effects will be at once apparent, not only in the shape of better growth, but also finer flowers.

Insects and Mildew.—The two other difficulties with which Rose growers on either a large or small scale have to contend are insects, such as aphides, red spider, and the Rose maggot, and also parasitic fungi; the Rose maggot will still be present, though not in such large quantities as earlier in the season, and can only satisfactorily be dealt with by hand-picking. Aphides are generally much more troublesome in confined private gardens than in the open spaces devoted to the cultivation of Roses by trade growers. I have tried all sorts of contrivances for fumigating them in the open air, but found them little more than a waste of time and material, for this reason, that the space temporarily enclosed around the plants for the purpose is too small to retain a sufficient body of smoke long enough to kill the insects. For their effectual destruction nothing is equal to syringing with Tobacco, Quassia, or soap and water, separate or combined. I have found that a weak infusion of Quassia or soap, combined with Tobacco water, not only kills the eggs of these pests, but every living insect which it touches. As the summer advances red spider may also be looked for, and if it be not taken timely in hand it not only completely spoils the appearance of the foliage, but has a correspondingly injurious effect upon the autumn flowering; a little Gishurst added to the Tobacco or Quassia water (which alone will not exterminate this spider) will kill it, but it must be used with caution, or it will cause the advancing bloom-buds to fall off. Water impregnated with sulphur will likewise kill red spider, and also mildew, which towards the end of summer is usually so injurious, especially where the soil is at all light and much sheltered from free currents of air. This decoction can be made by putting 8 or 10 gallons of clean water into a vessel, and adding 1 lb. of flour of sulphur, stirring the two up well once a day for a week or so, and using the water in a clean state, for unless so dealt with if the syringe be used very open one it will clog up. Liberal applications of water with the garden engine or syringe two or three times a week will be of great use in keeping down aphides and red spider. Except these matters are attended to there will be little else but disappointment, and in the case of private growers the mistake often committed is cultivating more than there is time to properly attend to; one-fourth the number usually grown well cared for, and sufficiently supplied with all that is necessary to invigorate them, will give very much more satisfaction than ten times the quantity left, as they often are in a great measure to themselves through the whole course of the season, with the exception of pruning, tying, and digging the ground, and the addition of often a very inadequate amount of manure. In large establishments where Roses are cultivated extensively for sale comparatively little attention is given or required, for where many acres of them are grown together, localities are selected in which soil, climate, and other conditions are most favourable for their growth, and where insect pests, mildew, and other annoyances that beset their growth in private gardens are very much less troublesome.

Rose Stocks.—Those who propagate their own standard and half-standard Roses by budding will need to see that the stocks do not suffer from want of water should the weather become very dry, otherwise the growth will be weak and puny, the buds when put in will be much less likely to take freely, and the aftergrowth will be proportionately weak. It is well to go over the stocks and to remove all the superfluous shoots that are thrown out from the stem, retaining some three or four at the head, which will be sufficient to favour the development of roots.

Pot Roses.—A great portion of the stock will now be either plunged out-of-doors, or in a condition for being so placed, and it is here during the pressure of the multifarious subjects which demand attention at this season that Roses are apt to get neglected; hence it is that pot Roses, except in the case of those who make a speciality of them, are often unsatisfactory, for no matter how much care is bestowed upon them during the time they are being forced or brought gradually into bloom under glass, as the case may be, comparatively little can be done to assist the production of flowers unless the plants receive all the attention that they need after the flowering season is over, as it is during that time that a great deal of their root development and shoot-growth is made, upon which depends their ability to produce a full complement of flowers. The foliage of Roses that have been grown under glass is necessarily more tender than that of such as are produced in the open air, and consequently more liable to both red spider and mildew, for the destruction of which a continual outlook is needed, and where either of these pests is present, means should be taken for their eradication. Where aphides exist the plants should be either dipped, syringed, or removed to a house or roomy pit that will hold a body of smoke sufficient to remain long enough to kill the insects. To fumigating in ordinary garden frames or such like contrivances there is the objection that the small volume of fumes which they hold so soon escapes, that to kill the insects it is necessary to apply the smoke so dense that it is liable to injure the plants. To pot plants again manure water will be of the greatest assistance, also to large specimens planted out within the different glass erections in which Roses are so grown, and which it is necessary to encourage by every means between this and the autumn to make as much strong growth as possible. On these likewise both animal and vegetable parasites should be dealt with as in the case of outdoor Roses, using every means at command to insure the production of as much healthy foliage as possible, and its retention in a fresh vigorous condition.

T. BAINES.

NEW ROSE STOCK.

ROSA POLYANTHA, of which the annexed is a representation, is strongly recommended in the "Journal des Roses" as a stock. It is a Japanese Rose, which bears single white odoriferous flowers, thirty or forty in a panicle, succeeded by obovate fruits of the size of a cherry-stone. M. Carrière states (Rev. Hort., 1876) that it makes sterile shoots of 6 ft. or upwards in length. Some seeds of it received from Japan in 1873, at the Botanic Gardens of Bordeaux, produced young plants of fine growth, in which, after the second year, an exceptional vigour was noticed, and since then numerous trials have proved that it may be advantageously substituted for the Briar as a stock. To provide these, strong bushes of it should be carefully taken up in November, and the stems separated, so as to preserve to each a piece of heel, provided or not with roots. The larger stems should be planted at proper distances apart, and budded in July or August, to make standards. The shorter stems, being more or less cut back, will make half-standards or dwarfs. The branches and pieces of stem up to the smallest sprigs should be reserved for cuttings which root readily, and the larger roots obtained

by dividing the stump can also be grafted, potted, and then placed on a hot-bed, where the grafts will speedily push vigorously. A cutting of this Rose of medium strength will furnish, after the first year, a stock fit to work as a dwarf, and in the second year one for a half or full standard.

INSECTS ON ROSES.

I do not remember a season in which Roses have been so much infested with insects as they are this year, as not only have they more than their share of aphides, but the maggot, a worse enemy, is rife among them, and is fast curling up the leaves and destroying the buds. To get rid of these pests by the ordinary means of washes or insecticides is quite out of the question, as owing to the manner in which they are enfolded amongst the foliage none of these can ever reach them, and where there are many plants, picking them out by hand is tedious work. The most effectual, as well as the most expeditious, way of dealing with the maggots is to go carefully over the plants and pinch them between the finger and thumb. Their presence may be readily detected by the bloated and partially twisted appearance of the foliage, and to make sure of their destruction, every leaf in this state should be operated on.

In dealing with green fly nothing is equal to a decoction made from Tobacco, Quassia-chips, soft soap, and Gishurst; this mixture is most powerful in its effects, and yet if used properly diluted so mild and harmless, as regards the Rose, as not to injure the most delicate leaves. The proportions in which I use it are 1 lb. of Tobacco and 10 oz. of the other three ingredients to 10 gallons of boiling water, which, bedewed on the plants at a temperature of 90° or so by means of a syringe, is almost sudden death to the aphides,

or they may be despatched by dipping the shoots into the mixture. Where they are not all affected, or the plants stand a long way apart, this is the most economical plan, as it involves less loss of liquid, although it takes more time. If the dipping or syringing be done over night and allowed to remain on till morning, it is generally more effectual than it otherwise would be, and there is less risk of injury than when the sun has more power; but in all cases a good washing with clean water should follow, so as to cleanse the foliage and knock off any stragglers that may be hovering between life and death from having partly escaped through not being exposed to the moisture. As a cure for mildew, pentasulphide of calcium is as good as anything if used in the proportion of a wine-glassful to a 4-gallon pot of water, and syringed on the plants in the evening; this destroys the fungus. Sulphur, too, dredged on when the foliage is moist with dew is a good remedy, but not so likely to reach every affected part.

S. D.

Roses at Cannes.—I do not think your answer to Captain Thomas's question as to Rosa alba Camellia in last issue (p. 446) can be correct, as the Ramanas or Rosa rugosa (or Regelia, as it was called when first introduced) has certainly not got smooth shining leaves like those of a Camellia. I should feel more inclined to think R. alba Camellia was the single Macartney Rose.—W. E. GRUBBLETON.

Rosa polyantha.

THE FLOWER GARDEN.

POTTING AURICULAS.

IN reply to "Brookhurst" (p. 429), who thinks Mr. Douglas wrong in recommending Auriculas to be repotted about the middle of May, I have only to uphold what I have always practised and written, and that is that these plants cannot be repotted too early after they have bloomed. I therefore think Mr. Douglas is right. All my exhibition plants are repotted immediately on their return from the show, *i.e.*, before April is out, and the rest follow in the order of their passing out of bloom. Mr. Douglas, happily, need not subject his plants to a turning out of pots and a long journey, but I needs must; and thus, over exhibitors from long distances, the London growers have this no mean advantage. The comfort and saving to comparatively undisturbed plants is something as grateful as the convenience to our own selves of a long railway journey in a thorough carriage compared with the evil and upheaval of having "to change." I am aware of what has been the practice among growers past and present, and that on the side of later potting there lies the authority of the late George Lightbody, of patriarchal repute in Auriculas. It would be very wrong to deny the success of that method, yet my own experience points to equal safety and greater advantage from earlier potting. I deny plainly that potting in May is likely to induce autumn blooming. Those whose plants indulge in that ill-timed display have other causes to blame for it. It may be that they are rich in varieties of a naturally restless habit, which persistently will bloom twice or oftener in the year, treat them how you will. Or it may be that a collection has suffered from some summer maltreatment such as being kept too hot or dry. Upon plants in such distress the effect of moist cooling autumn weather will be a sudden joy capable of driving them out of their course, while if life itself has been in danger they may make attempt to flower in accordance with the instinct there is in vegetable nature that presses a dying plant to save its species by rushing into seed-bearing just as we might sometimes see an ill-conditioned Conifer expiring in a convulsive production of cones.

Auriculas will take no visible harm by being left undisturbed for a few weeks after blooming, and those entrusted with valuable seed-pots it is well to let alone awhile. But in early repotting there is not that fatigue, and there is not that check which light assertion and theory may attribute to it. Rather is the spent plant in better time relieved of fibres that have died and of stem become inert, while the white, young, vigorous roots, bristling from higher seats of life around the leafy neck, are ready for new food and less damageable than when grown longer. Other roots are also encouraged to push out, both by the need the plant has of them and in that very appetite which the relish of fresh soil creates; and should there, by illhap, as I have known it, be any distasteful element in the compost, which an Auricula soon discovers, there is the grand resource still left of time enough to try again and remedy the evil without the fatal loss of a season.

I have found these early-established plants settle down best to their work and as safely in autumn as at other times, go calmly on, too, contented to do a discontented act. Although I grow a few of the uneasy sorts, I have noted that the extent of my autumn bloom ranges only from about 2 to 5 per cent., this does not include the young seedlings of a year old or so, for these have tricks and manners of their own, and it is not excessive, seeing that the Auricula, as a member of the Primula family, may be expected to indulge somewhat in autumn blooms, even as will the commonest Primroses and Polyanthes.

F. D. HORNER.

Kirby Malsward, Ripon.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

White Mould on Auriculas.—If "R. D." will refer to the reports of the Scientific Committee of the Royal Horticultural Society, dating some two years back, he will find this subject fully discussed and "settled." Mr. Dombrain and some other Auricula growers described the white material as a sort of American blight, and some of the substance was submitted to Mr. W. G. Smith for examination, and that gentleman described it at once as an animal production. This idea was looked upon with disfavour at the time, and no one threw more stones at it (in a good-natured way) than the late excellent Mr. Andrew Murray, who wanted the stuff to be a fungus. Some one now took Mr. Smith's side, and said he had actually seen the insects embedded in the material on the Auricula roots, and the matter was at last settled by an exhibition of infected plants with the white substance and insects *in situ* on the occasion of the visit of the Queen. Mr. Murray then frankly acknowledged his error and described the insect.—A.

When to Plant Tropæolum speciosum.—Many fail in getting this plant to establish itself, a circumstance which, in my opinion, must arise from planting it at the wrong time; for I find that by taking it up after it has commenced its growth, every bit that has a small portion of the fleshy part of the roots attached to it will live and grow as if nothing had happened. I manage to furnish the whole end of a house in this way, and I could now increase this Tropæolum at least tenfold, as small pieces are cropping up through the border in all directions. Any one wishing to possess it will do well to obtain plants of it now and plant them at once, as by so doing they will have time to form fresh tubers before they ripen off in the autumn. The situation most favourable for their growth is the side of a north wall, or the shady end of a plant house, as there they are able to maintain their leaves fresh and green and free from red spider. In Scotland, where the climate is colder, this Tropæolum grows very freely, and, by keeping it properly watered during the summer time, and giving it an occasional syringing, it may be had almost anywhere nearly as good as it is there, the principal thing being to maintain the foliage fresh, without which this plant never gets on. I find that wires or strings strained vertically about 6 in. or 9 in. apart answer best to train it on, as then the young shoots continue their ascent instead of being diverted from their course and becoming an entangled confused mass.—S. D.

Lilium Batemannianæ.—"T. H. A. H." (p. 430) thinks that the figure of this Lily given in THE GARDEN (p. 366) is identical with that given in the Bot. Reg., 1839, as *Lilium aurantiacum*. We quite agree with him that the latter plant is the original *L. Thunbergianum* type. It grows from 12 in. to 18 in. high, and we have described it in our catalogue (No. 40) as the long-lost, beautiful, unspotted Lily figured by Paxton, and called by him *L. aurantiacum*, having large, erect flowers of a rich salmon-yellow colour, quite destitute of spots; its foliage and habit are of the true *L. Thunbergianum* type. But *Lilium Batemannianæ*, as described by us in THE GARDEN (p. 396) grows from 3½ to 4 ft. high, and in habit of growth and foliage resembles *L. Leichtlini* or *L. Maximowiczii*. The flowers are much more numerous, but smaller, than those of *L. aurantiacum verum*. If your correspondent would grow the two forms side by side, he would soon recognise that there is a great difference between them.—ALEXANDER WALLACE, *Colchester*.

Wild Flowers for the Garden.—"B." may well ask (p. 407) why these are not more used in gardens than they now are. With but little trouble a most beautiful border might be made with British plants alone, and, in the case of those whose gardens are large, I cannot imagine a more interesting experiment. Even here, within fifteen miles of Hyde Park, I have found and added to the garden—the wild Tulip (*T. sylvestris*), the Snake's-head Fritillary (*F. meleagris*) and its white variety, the Marsh Marigold (*Caltha palustris*), Water Forget-me-not (*Myosotis palustris*), the Yellow Iris (*I. pseud-acorus*), Lent Lily (*Narcissus pseudo-narcissus*), Water Lilies (*Nymphaea alba* and *Nuphar lutea*), Meadow Sweet (*Spiraea Ulmaria*), the Ivy Linaria (*L. cymbalaria*), and several others of almost equal beauty. My list would be too long if those plants which have been collected from more distant parts of the kingdom were added, so I must conclude with one only, *viz.*, *Pinguicula grandiflora*, a large-flowering kind which is a gem amongst bog plants.—A. K., *Eastcot, Pinner*.

A Good Bedding Forget-me-not.—This is a seedling said to be an improvement on *Myosotis dissitiflora*, which it somewhat resembles, but it differs from that kind materially in being more compact and dwarfier, a more profuse bloomer, and, above all, in being much harder, as it has withstood the past winter with impunity, and the beds in which it is planted have not a vacant space in them, whilst those near them planted with *M. dissitiflora* are bare, all the Forget-me-nots having succumbed to the severe cold. Such a desirable variety as that above alluded to is well worth a distinctive name by which it may be known when it becomes more common.—W.

Lobelias from Cuttings.—Where a large stock of Lobelias is required true for beds and borders, nothing surpasses getting them from cuttings, as they grow so much more uniformly than from seed. We usually remove the flowers from a few dozen plants of each sort early in autumn, in order to induce them to make a little growth before they are lifted and stored in boxes for the winter. Early in spring the cuttings are taken off and inserted thickly in boxes of sandy soil in a moist heat, where they strike without much loss. They may then be planted in cold pits, where they make fine plants for turning out in May.—J. G.

Seedling Mimuli.—Some fine blooms of these have been sent to us by Messrs. Downie & Laird, Pinkhill Nursery, Corstorphine. They are large, rich, and well varied in colour and spotting, and of good substance.

CHIONODOXA LUCILLE.

THIS, the subject of the accompanying illustration, is without doubt, the finest addition that has recently been made to our list of hardy spring-flowering dwarf bulbous plants. Its habit at once reminds one of the two-leaved Squill (*Scilla bifolia*), as it rarely develops more than a pair of leaves. The blossoms, from five to ten in number, are produced on gracefully arching stems, from 4 in. to 8 in. high, and are each nearly 1 in. across, star-like in form, and of a beautiful clear blue tint on the outside gradually merging into pure white in the centre. As to its hardiness, there can be no doubt, as it has withstood the past winter with impunity, and flowers freely during March and April. Some misapprehension has existed as to its nomenclature, but now, we believe, it is clearly understood that *C. Forbesi*, which was considered distinct, is synonymous with *Lucille*. It is a native of Asia Minor, whence it was introduced by Mr. G. Maw, who discovered it a year or two ago at Nymph Dagh. W. G.

VEGETABLE CULTURE FOR MARKET.

BROCCOLI—This crop is grown by market gardeners near London chiefly under the shade of fruit trees, but in the

valley of the Thames there are acres of Broccoli in open fields. The early supplies of Broccoli brought to the market are produced in the west of England, where the climate is mild, and the heads produced there are infinitely superior in size and quality to those grown nearer London. In mild seasons Broccoli is so good and plentiful as to be of little profit to the grower. In the winter of 1878 many never brought their produce to market at all, but made use of it at home, so low were the prices offered for it in the market. In the market gardens about London, the Purple Sprouting, the Walcheren, Snow's

Winter White, and Cock's Late White are the kinds chiefly grown. The first sowing is usually made during the month of April on beds of rich soil. Sometimes, however, the time of year when ground will be vacant to receive the plants materially influences the time of sowing, for it is an important matter to have the young plants healthy and stocky at planting time. If sown so early as to have to be kept long in the seed-bed they become drawn, and consequently do not yield such good results. Another sowing is generally made in the middle of May; indeed, from this sowing the principal winter crop is obtained, and more plants are raised than are required, so that all clubbed and weakly ones can be discarded at planting time. A sowing of sprouting Broccoli is made in the end of June or early in July, from which is obtained a supply of Sprouts in the following March and April, a time when they are in great demand. When the young Broccoli plants appear above-ground they are first hand-weeded, and afterwards thinned by means of narrow hoes. As soon as they are strong

enough for transplanting they are planted in rows under fruit trees, or in some other shady situation, or in an open quarter, as the case may be. When planted between rows of fruit bushes, two lines are inserted in the intervals between every two rows; but if two drills of Potatoes occupy this space, then only one line of Broccoli is planted, and that between the two drills of Potatoes. Should the whole space under an orchard be planted with Potatoes, as soon as these are earthed up, Broccoli is planted between the rows without the soil being loosened. The Potatoes ripen before the Broccoli can injure them much, and when the Potatoes are removed the Broccoli has the whole space to itself. The trees lose their leaves in October; therefore the Broccoli, having the benefit of increased light, becomes invigorated, and during that month and November begins to afford a good supply of sprouts, which are not all gathered at once, even from the same plant, but at intervals as they become fit for use. The immense breadths of Broccoli grown in some of the market gardens render it almost a matter of impossibility to have all heeled

in the same as we often see them in private gardens; yet it is very seldom they are injured by frost, and the fine white, firm heads that may be seen by thousands in Covent Garden Market during the autumn are seldom surpassed, if even equalled, in private gardens. In the neighbourhood of Shepperton, in the Thames valley, may be seen breadths of Broccoli from 20 acres to 30 acres in extent, and from this place alone it is calculated that in the height of the season as many as 30,000 heads per week are sent to market. In some parts of Kent Broccoli is grown to a large extent, one

Chionodoxa Lucille.

grower yearly planting over 200,000 plants.

CAULIFLOWER.—With this it is hardly possible to overstock the market. It has the advantage over Broccoli in this particular, viz., that pickle merchants are always ready to buy up any quantity of Cauliflowers in summer, whilst for this purpose scarcely any Broccoli is used. In May, before Peas and Beans can be had at reasonable prices, good Cauliflowers realise good profits to the grower. Early Cauliflowers are usually grown under handlights, or are protected by old baskets or small boughs of evergreen trees. To provide plants for this purpose, a sowing is made on a well sheltered piece of ground or a warm open quarter, in beds, in the second or third week of September. The young plants are allowed to remain in the seed-bed until the end of October, or even the middle of November. Should frosty weather set in whilst the plants are in the seed-beds, they are protected by mats supported on short stakes 18 in. above the ground. Sometimes a stout plank is set on edge along the centres of the beds, and two rows of short stakes are put

one on either side to support it, and over this are placed mats. When the weather becomes too severe for them to be thus protected, and when they require to be transplanted, they are taken up and planted in frames or under handlights. The frames are placed in a sheltered spot sloping to the south, and are filled to within 8 in. or 9 in. of the top with ordinary soil firmly trampled down with the feet; over this better soil is sifted to a thickness of 3 in. or 4 in., and in this the Cauliflowers are planted 3 in. or so apart. In this position they remain until the February following and early part of March without any further care beyond that of closing the sashes to exclude frosts, cold winds, hail, or rain, and tilting them up at front and back during favourable weather, and on very fine days drawing them off entirely. Cold rains are very injurious to Cauliflowers, but a warm shower in February benefits them. Sometimes the plants grow so strongly that their leaves touch or press against the sashes; when that happens the sashes are tilted up at front and back night and day with pieces of wood or brick, otherwise frost would injure such leaves as touch the glass. Dry sand, kept in a shed for the purpose, is scattered amongst the plants two or three times while they are in frames, in order to guard against damp, and such plants as show signs of "buttoning" are immediately pulled out to give the others more room. Where room is limited and the weather appears mild, young Cauliflowers are often wintered in the beds where they are sown, or they are pricked off into raised beds of light soil not likely to be soaked with wet in winter. Here they are sometimes left unprotected, and at other times they are covered with hoops and mats. Continued dampness of soil and atmosphere is their worst enemy, as it induces growth so soft that it cannot withstand frost so well as that produced on high and dry ground. Where handlights are employed, an open field or quarter is lined off into squares measuring about 6 ft. each way. At every intersection nine Cauliflowers are planted in a sufficiently small space to be conveniently covered with cloches or handlights, which are immediately placed over them, and a little earth is drawn around the base of the lights so as to shut up all apertures. The empty spaces between the rows of handlights are planted with Coleworts. In spring these Coleworts are either thinned out, or entirely removed for market, and a crop of Cos Lettuces is planted in their place. As soon as the Cauliflowers have become established they are allowed abundance of air, and otherwise treated the same as those grown in frames. When the plants become too thick, they are all lifted from under the handlights and planted in open quarters or under other handlights.

Market gardeners generally begin to cut from Cauliflower plants raised in this way some time in the month of May, according to the mildness or otherwise of the season. The best growers seldom make many sowings of Cauliflowers; one or two in autumn, and one or two in spring being the usual number. The first autumn sowing, as before stated, is made out of doors some time between the last week in August and the third week in September; and the second one, in frames, in the last week of September or first week in October. From these two sowings Cauliflowers are obtained from the last week in April to the end of June. The first spring sowing, if the autumn one is a failure, is made in a frame in the last week of February or first week of March, or it may be made in the open border any time during the first fortnight of March; from this sowing a crop is obtained from the middle of June till August or September. The third sowing is commonly made in beds, in some open quarter, between the middle of April and the first week in May, in order to furnish an autumn supply. Different market gardeners have different times for sowing Cauliflowers, but it is well understood that

strong, grossly-grown plants do not stand the winter so well as medium-sized ones, and they are also more liable to "button." Moderate-sized plants are decidedly the best for mild winters, but in the event of very severe winters occurring, strong plants are the best. Cauliflowers which have been wintered in frames or under handlights are often planted on ground cropped with Radishes before the latter crop is marketable, and by the time it is so, and cleared off, the Cauliflowers will have gained good strength, when the ground will be intercropped with Lettuces. In other instances, fields are marked off into beds 5 ft. wide, with 1-ft. alleys between them, and these beds are sown with round-leaved Spinach. As soon as this is done, three rows of Cauliflowers are planted along the beds. The latter outgrow the former, which, by continual picking for market, is kept in check until it is eventually exhausted, leaving the Cauliflowers masters of the field. The autumn crops obtained from spring sowings are thinned out a little in the seed-beds, and, when large enough for handling, are planted where they are to remain permanently. Should the weather be dry at planting time, a pint of water, or a little more, is given to each plant, and the sodden soil is soon afterwards freshened up by the hoe, thus, in some measure, preventing evaporation. Late Cauliflowers are nearly always intercropped with some other vegetable, such as Lettuces, French Beans, Celery, Seakale, &c. Some large growers, however, depart from this rule, and save much labour; for, if intercropping be practised, people must be employed to keep down weeds by means of the hoe; but when Cauliflowers alone occupy the ground horse-hoes can be freely worked among the rows. The Early London is the variety used for the first crop by most market gardeners, but some use the Walcheren for that purpose. The Walcheren is the kind almost entirely grown for use after June, because it suffers less from drought than any other sort, and is not liable to "button." Snow's Winter White, an excellent sort, is, as a rule, regarded as a Broccoli; nevertheless, it has fine white, solid heads, and is largely grown to succeed the Walcheren, being harder than that sort. Snow's White, if sown together with the Walcheren in April or May, makes a fine succession to it, and comes in usefully till January. Early Cauliflowers are always sent to market, but those produced in summer and autumn are disposed of to a large extent to pickle merchants.

SPINACH.—During winter and spring Spinach finds a ready sale; but when other vegetables, such as Beans and Peas come in, it is little thought of. Market gardeners seldom grow it as a summer crop, as it "bolts" or runs to seed before many leaves have been gathered from it, and in that case it is by no means a profitable crop. The round-leaved sort is that which is used for spring sowings, the first of which is made in February, a second about the 1st of March, and another sowing or two at an interval of three weeks or thereabouts, just as empty space and convenience permit. The latest spring sowings are made on a damp, cool piece of ground, provided such can be obtained, as, thus circumstanced, better leaves are produced in hot weather than on dry and warm soils. In July, if the weather be moist, a sowing of the round-leaved variety is usually made on a spare piece of ground for autumn use. Early in August a large sowing of the Prickly-seeded or Flanders is made broadcast on fields or in rows about 8 in. apart. Some growers prefer the Flanders on account of its large fleshy leaves and hardy constitution, and it sells in the market better than the Prickly sort. By sowing in the first and last week of August and the middle of September, a succession of Spinach from October till May is easily kept up. Although during winter but few leaves are produced, the earliest sowings yield freely before then, and

the two latter abundantly in spring. Coleworts are frequently planted in a field of late Spinach, at 3 ft. or 4 ft. apart. In damp winters a large proportion of the roots may die, but in ordinary winters they retain their vitality, and produce abundance of large fleshy leaves in spring. No care is taken with this crop from the time of sowing till gathering beyond hoeing and thinning once or twice. Spinach for market is packed firmly in round baskets, and also in hampers of any size convenient for handling. Spaces under fruit trees are also often covered with Spinach sown broadcast; and as the trees are not furnished with leaves, they do not shade the plants. Open fields are also often sown with Spinach in beds, which are covered by throwing soil over them from the alleys; on these beds Cauliflowers are also planted, at the usual distances apart. By the time the Spinach has come well up the Cauliflowers will have become well established, so that the Spinach, which as soon as ready is removed for market, does not injure the Cauliflowers much. When the Spinach is removed, the Cauliflowers are permitted to have all the space; consequently the ground is gone over, hoed, and allowed to rest for a few days, when some soil is drawn to the Cauliflower plants.

VEGETABLE MARROWS.—The abundance of Vegetable Marrows to be seen in Covent Garden and the streets of London during summer and autumn gives some idea of the extent to which they are grown in market gardens. Although they are often sold at a cheap rate, yet the productiveness of the Vegetable Marrow renders it, in good seasons, one of the most profitable of crops. The jam and marmalade manufacturers use large quantities of Vegetable Marrows, and private individuals often turn them to a similar account. When well made, Vegetable Marrow jam is wholesome, and much better than some of the questionable jams which one often sees sold in the poorer shops. Early in March hotbeds are erected for producing Vegetable Marrows, the seed of which is either sown thickly in pots or pans of common soil plunged in the beds, or sown broadcast on a bed with a few inches deep of soil placed over the fermenting material. As soon as the plants show two rough leaves they are pricked into other beds or into pots. The usual method is to prepare a series of frames set on slightly heated hotbeds; on the surface of these place a few inches deep of soil, into which plunge 6-in. pots, filled with common garden mould to the brims, as thickly as they can be stowed together. Into each of these pots two Marrow plants are dibbled, and here they remain till planting time, hardening them off by gradual but increased exposure in fine weather. The first plantation is made out-of-doors during April, but the plants make little progress until the end of the month. When ridge culture is practised the ground is marked off in lines for them about 10 ft. apart, and each plant is about 6 ft. or 8 ft. asunder in the row. Where each is to be planted, a hole about 20 in. deep and 2 ft. or 2½ ft. wide is dug and filled with fermenting manure, which is covered over with the soil that has been thrown out in the excavation. Here the plants are planted, the contents of one pot being put in every ridge, and covered over with handlights or large cloches. A little earth is at first drawn around the base of the lights, so as to keep all close and free from cold currents of wind; and, in the event of frosty or cold windy weather setting in, mats or litter are also placed around and over the lights. Excited by the heat from the fermenting manure beneath them, and protected from cold overhead, they are almost as snug as in a hotbed, and, consequently, they soon take to their new quarters, form fresh roots, and begin to grow. When this is the case, the lights are tilted up a little on the south side, by means of half-bricks or small flower-pots, during favourable opportunities, but shut up at night. When growth,

however, begins to make rapid progress, the lights are left a little tilted up at night, so as not to injure the shoots that are pushing forward, and require more room than is afforded under their little glasshouses, until finally the lights are entirely removed, which will probably be in the latter half of May. From this plantation fruit is generally cut in the first or second week in June, depending on the warmth of the season. Large growers have generally from four to six plantations of Marrows, each succeeding the other by a fortnight, so that the last planting is made late in June. Midseason crops are planted on ground just cleared of Radishes. If the Radishes be not cleared at the time of planting, the Marrows are planted in every alternate alley between the beds, thus permitting the Radish crops to be removed at convenience. For the later crops, ground occupied by spring Spinach, Radishes, autumn-sown Onions, Cabbages, or Cauliflowers, forms a good medium. The space between the rows is not lost during the minority of the Marrows, but is cropped to within 2 ft. of them with Lettuces, in addition to which there are generally three or four lines of Cabbages or Cauliflowers planted along the centre of the space. Turnips also sometimes form the inter crop.

During the early stages of growth, if the weather be dry, little basins of earth are drawn round the plants to form a hole for the retention of water, of which they get a good supply until their foliage covers the ground. The plants begin to fruit when the vines are 3 ft. or so in length, and continue growing and fruiting until frost, drought, or mildew renders them useless. In a dull rainy season, provided it be warm, they thrive apace and fruit heavily; but in a hot and dry one they are short-lived and less profitable. When they are growing pieces of stone or brick are sometimes placed on the advancing vines as they are pegged to the ground, to cause them to root at the joints and thus afford themselves increased means of support. No care is, however, taken of them as regards thinning the overcrowded vines; but sometimes the growers mulch the ground with litter, which not only enriches it, but preserves its moisture, prevents to some extent evaporation, and keeps the fruit clean from grit. As soon as the plants begin to bear, every fruit is gathered when it attains a marketable size, for if left too long, they render the plant less fruitful. They are gathered three times a week, the gatherers being supplied with fruit-collecting baskets, a stick, and a knife. With a stick they turn aside the leaves of the plants in search of the Marrows, and they are thus enabled to go over the ground quickly. When each gatherer has filled a basket, it is carried to the outside of the plantation and emptied into a heap, or into large baskets, or a waggon stationed there to receive them. The trampling the Marrows undergo in the process of gathering does not seem to injure them much. In August some good fruits are selected and marked by inserting an upright peg alongside of each, and these are allowed to remain untouched till ripe, when they are cut and placed within frames or in exposed situations before the sun, so as to become thoroughly ripened. They are afterwards placed in a corner in some of the sheds, to await a convenient season for extracting and washing the seeds. After the middle of September Vegetable Marrows are commonly useless, and the demand for them diminishes; consequently, they are not after that time worth the ground they occupy. Sometimes they are cleared off the ground at once, and at other times they are left until frost completely kills them; but in all cases the haulm is raked off and carted to the manure heap before manuring or digging the ground, which is usually planted at once with Coleworts. Custard Marrows are grown out-of-doors on the same system as early Vegetable Marrows; but as they are weaker growers than

the latter, they are only planted about 8 ft. by 6 ft. apart. The ground is also, as a rule, mulched all over, and in the event of dry weather they get occasional good waterings. The marketable value of Vegetable Marrows varies very much; sometimes they hardly pay the grower, whereas at other times they are highly remunerative, much depending on the scarcity or abundance and the price of Peas, French Beans, Cauliflowers, and other vegetables. The chief variety grown is a selection from the old Cream Marrow, which is of first-rate flavour, hardy, and a prodigious cropper.

THE KITCHEN GARDEN.

ECONOMICAL ASPARAGUS CULTURE.

ALONG with this I send a bundle of Asparagus cut from plants two years planted, and which have been grown without any special preparation of the land. As will be seen, the heads are not particularly large, as I am more anxious to secure a great number of quickly-grown, tender, medium-sized heads than a few of extra size. For this reason I cut last year a few of the largest, in order to equalise the growth, as the size of the heads is governed by the preceding year's shoots; and if we wanted them very large, I should encourage the largest stems by removing the weakly ones; but, as I have already stated, I last year cut those that were above the average in size, and the result is a good yield of heads about the size of those which I send, and no small ones; consequently, there is no waste. The land had previously been used for growing vegetables, and therefore was in fairly good condition, both as to depth and manuring. The plants, when planted two years ago, were one year old, and were strong for that age, having been sown thinly and further thinned out to about 5 in. apart, and when they were planted all weakly ones were rejected, so that a good average growth was by this means secured.

I should not recommend young plants to be raised on land much richer or lighter than that which they will finally occupy. I have seen instances of the bad effect of transferring plants raised on light rich land to that of a poorer character. The opposite case would not be so objectionable, although it is not desirable to plant half-starved plants raised on poor land at all if it can be avoided. The planting was done when the young shoots were about 2 in. or 3 in. above the ground, lifting them up carefully, so as to retain all the roots unimpaired; and they were planted as speedily as possible, as much exposure to the air would be injurious, and it is better to plant in dull weather. Lines were marked out across the plot 3 ft. apart, trenches were opened with the spade of sufficient width to allow of spreading out the roots, and, as our land is porous and often suffers from drought in summer, the trenches were taken out deep enough for the plants, when finally covered with about 1½ in. of soil, to stand in a hollow about 3 in. or 4 in. below the natural ground level. I should remark, however, that this hollow has since been filled up with compost formed of the clearings of the rubbish-yard, which is often of a light mellow character, containing a good deal of vegetable matter. Beyond a sprinkling of salt, this is the only manure which the plants have had, and they have never had liquid manure or water of any kind given artificially, although I should have given them some if time and circumstances had permitted.

I should state that when the plants were first planted it was intended for each to occupy a square yard, but I thought for a year or two no great harm would be done by putting in a double number, so that, although the rows were 3 ft. apart, the plants in the rows were only 18 in. asunder. I believe that this was a mistake, as well-selected Asparagus plants will profitably occupy at least a square yard, even on inferior soil, from the very first. The plants have seeded most abundantly, and I have never yet been able to spare the time to pick off the seeds in the way I should like, as seeding must be exhausting, and when the seeds ripen on the stems some may drop and grow, and perhaps be permitted to stand, unless a close eye be kept over the rows, in order to see that the spaces are left unoccupied. With this system of culture one need never be bothered with beds of old weakly plants, as one might plant a patch every year or two and destroy a corresponding patch, and so Asparagus culture might be brought on to a regular system of rotation.

E. HOBDAV.

[A very remarkable result for the time, though the benefit of such a system will be far more apparent as years go on than when the plants are young. The Asparagus was very delicately flavoured.]

GARDEN DESTROYERS.

A Tree Borer.—Great havoc is being made among the Sugar Maples in the province of Ontario by the Maple Tree Borer (*Clytus speciosus*), an insect which seems particularly busy among the trees which are planted in the streets. As a preventive measure it is recommended that towards the end of June, or the beginning of July, a coating of soft soap and lye, reduced to the consistency of cream, be applied to the bark of the trees on a warm day. Such an alkaline coating is found to be particularly objectionable to this insect, which seldom deposits its eggs upon such a substance; or if by chance they are deposited, the larvae perish in the attempt to penetrate. During the day-time these beetles are generally seen resting quietly on the trunks of the trees, but at night they are exceedingly active. During the months of July and August the eggs are laid upon the trunks of the Maples. The long fleshy grubs hatched from these have six legs, which may be said to be rudimentary, as they are useless for purposes of locomotion. By means of the rings or segments of their bodies, which they contract and extend alternately, the insects force their way through the wooden tunnels which they make in the trunk. They are furnished with strong horny jaws, which enable them to pierce the hardest wood. After penetrating through the bark, they lie dormant during the winter. On the approach of spring they penetrate the wood, forming numerous winding galleries in the trunk. At the end of the year the larvae become changed into pupae, and afterwards into the matured beetle, which forces its way out through the bark to attack other trees.—A. J. B.

Wireworms in Potting Soil.—To get rid of wireworms and other pests from potting soil, leaf-mould, &c., I find it a good plan to place it for a day or two in the hen pen. The cocks and hens turn over every particle, and I believe they pick out every grub and egg in a most effectual manner.—BROCKHURST.

ANSWERS TO CORRESPONDENTS.

Vanilla Tree.—Can you tell me what tree this is? It is mentioned in the "Times" as being planted largely in Paris, and now masses of purple bloom; it is also recommended for town planting in this country.—A. M. A. [Possibly the Japanese *Faulstichia* *imperialis*, which bears flowers of a purplish-violet colour, but they are produced too early for the trees to make a good display in this country, except in very favourable situations.—W.]

Disa grandiflora.—Kindly inform me the best method of growing this lovely Cape Orchid.—A. R. [It should be grown in a cool, airy, and slightly shaded house, one having a northern aspect being most suitable. The compost should consist of equal parts of fibry peat and loam, broken charcoal, chopped Sphagnum Moss and sand in small quantities, and a layer of chopped live Moss should be placed on the surface. Water should be given liberally during the growing season, and an occasional watering with weak manure water will be beneficial. Frequent syringings should be given in order to keep in check thrips and other insect pests. The offsets should be taken off as soon as rooted, or the flowering stems will be weak.—W.]

Willow Beetles.—What are the enclosed? For the past three years they have entirely spoiled the whole of our Willow beds, consisting of about an acre and a half.—F. D. [The beetles sent belong to the large family Chrysomelidae, the members of which are plant eaters, and often do very great injury. The name of the species which is so destructive to the Willows in question, is *Phoratra vulgatissima*. Collecting and destroying them is the only way of getting rid of them, a plan difficult to effect on a large scale.—W. S.]

Grubs Attacking Carnations.—What is the name of the grubs enclosed? and how can I best clear a bed of Carnations of them? One is found at the root of each plant, eating the fibres, and of course killing the plants. The latter were turned out of pots this spring.—B. O. [The grubs sent belong to the family Tenebrionidae, and are known as leather jackets. They should be carefully looked for whenever a plant appears in the least unhealthy and destroyed. There is no better remedy than continually hunting for the grubs, which will be found very near the surface of the ground.—W. W. S.]

Sorrel in Ferneries.—I have a hardy Fernery which is covered with Wood Sorrel. Is it likely to injure the Ferns?—S. H. [No; that is, it keeps within bounds.]

Names of Plants.—*W. A. B.*—*Ornithogalum nutans*, *Scilla italica*. *Sir W. M.*—*Ornithogalum nutans*. *F. B. L.*—Double Peach (*Amygdalus persica* fl.-pl.); *P. Pyrus* (*Malus*) *floribunda*; *C. Cupressus Lawsoniana*; *A. Aerides* *crispum*. *A. B.*—We cannot undertake to name double *Petunias* or double zonal *Pelargoniums*. *J. S.*—*Lilium elegans* var. *aluacolum*.

Questions.

Camellias and their Various Modes of Culture.—In the article on this subject (p. 413) "Cambrion" advocates that Camellias should have full exposure to the sun, both when under glass and when placed out-of-doors. Until a few weeks ago, when I heard it, I ported that Mr. Hovey, of America, had said that he placed his out-of-doors Camellias in the shade of the sun. I thought it was essential that all Camellia plants, even when placed out-of-doors, should be protected from the direct rays of the sun to prevent the foliage from being blistered or injured. It would be a great convenience to me if I could place my Camellias out-of-doors from the end of June to October in an unshaded place, and I should like to know whether I could do so without risk of injury to the foliage. I have had the foliage (old, not young growth) of plants in an unshaded, freely-ventilated house blistered by the sun so early in the season as April, and I cannot help thinking there must be some reason in placing them out-of-doors in a sunny place, especially from the effects of a bright sun following a shower of rain.—ENQUIRER.

"This is an art
Which does mend Nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

AN ERROR AS TO ASPARAGUS.

REFERRING to large Asparagus, a writer ("J. S.") in last week's "Gardeners' Chronicle" makes the following remarks, which are an echo of what is commonly said on a subject of some importance to all who care about Asparagus culture: "In the matter of cultivating Asparagus I believe we have a good deal to learn, for in few gardens do we find it at all equal in size to the immense heads sent over from France. The delicacy and rich flavour of these, however, are, in my opinion, quite spoiled by the blanching to which they are subjected, as instead of being tender and eatable from 4 in. to 6 in. or so of their length, only just the tops can be used, and even that portion compared with such as is exposed to the full influence of sun and air, is insipid and watery, and yet there are many who still give it the preference." There is an amount of error in such utterances which would make them amusing if they were not also detrimental to a fair understanding of the subject. The delicacy of blanched Asparagus is in no way spoiled by the process of blanching. It is a gross error to suppose that "only just the tops can be used." The writer's ideal of Asparagus is that it ought to be from 4 in. to 6 in. in length. I have frequently eaten the Asparagus which he states to be so useless perfectly tender 8 in. in length. It is also a mistake to suppose that this Asparagus is "insipid and watery" in any case where it is not badly cooked or in bad condition from being kept too long after cutting. There is also an important error implied in the paragraph, and that is, that only French Asparagus is blanched. Now, as a matter of fact, English market-grown Asparagus is, to a great extent, blanched the same as the French, and is none the worse for it. On the other hand, much French Asparagus comes to the London markets green, and is used in that state—that, for instance, which comes from the neighbourhood of Toulouse, while the Dutch Asparagus is far more blanched than English or French, being quite white throughout. The question of blanched or unblanched Asparagus has, happily, nothing to do with culture, which may be carried out without any reference whatever to whether we want it blanched or green, but the error as to the quality of blanched Asparagus is so common, and so often repeated, even in professional journals, that a few words on the question of blanching may not be amiss.

Errors about it have mostly arisen from the fact that some who purchase large French Asparagus frequently do not know how to cook it, and serve it with no part tender but the tops; they also often get it after it has been a long time exposed in shop windows and in markets—a most unfavourable condition for a vegetable, which loses its flavour very quickly when exposed to the air. The cookery which suffices for common small green Asparagus will not do for these large and fine specimens. They require to be boiled, and are boiled by all cooks who know how to treat Asparagus, standing erect in the water with the tops just out of it, all the stems being cut exactly the same length. The stems are then boiled till tender, and in this process the tops, exposed for about 1 in. of their length, are also cooked tender.

Recently I had an interesting test of this matter. A gentleman taking the keenest interest in all culinary matters spoke to me concerning this very subject, and avowed the usual prejudice about the green Asparagus. I told him about

the cooking of it, which seemed to strike him as being worthy of trial, and he at once resolved to try one of the best French samples procurable; I at the same time procured for him one of the very best English samples slightly blanched, so that he might make a comparison, feeling certain that he would give preference to the English Asparagus. This was not so; the large and fine French specimens, properly cooked, were found tender throughout, and of the most delicious flavour. All those who really know anything about Asparagus, such as Mr. Webber, and many of the people belonging to Covent Garden, know all this perfectly well, as anybody may find on speaking to them on the subject.

There is really a good deal to be said for the blanching of Asparagus which is supposed to be merely a matter of fashion, and perverse fashion. It is not likely that growers, who have to live by cultivating Asparagus, and who, as a matter of fact, satisfy the requirements of the most critical and most accomplished cooks that are known, would go on for years cultivating Asparagus in a vicious way. I have myself made numerous and repeated comparisons as to the flavour of Asparagus, and know it to be most delicate and excellent in the case of many blanched kinds, such as one gets from Argenteuil, or from Mr. Harwood, of Colchester, or from some of the great growers of the west of London, whose Asparagus is generally blanched, but not quite so much as that grown about Colchester; but all such tests must be made under fair conditions; the cookery must be right, and the Asparagus must be fresh. On the other hand, many samples of small green Asparagus are also delicate, and somewhat distinct in flavour from that which is blanched, but mostly when the young points do not push far out of the ground. Then, again, I have certainly found many specimens of long green Asparagus deficient in flavour, and in several cases without even the natural flavour of Asparagus. Whether this results from exposure or from the peculiarity of the soil, I have not yet ascertained. It may be soon noticed by those who watch the shoots of Asparagus how very soon in warm days those exposed begin to get scaly, and even to break out into buds, in which case, if not cut promptly, they will certainly soon be useless for the table. Herein there is a reason for blanching apart altogether from the question of flavour, which many good judges know well to be superior in the case of the finest blanched Asparagus. If, when properly cooked, the blanched stem be tender and well flavoured, it is manifestly an advantage to the grower to increase the length and size of this stem by the process of blanching. Instead of allowing his shoots to come up and break forth into very small spray, by this simple process he conserves, as it were, the strength of the rising shoot in the form in which it is most profitable both to him and the consumer. A bundle of these large, long, and well-grown shoots, not broken out into scaly or green matter anywhere, is a very different thing in the market from one of green points, keeping better and cooking better. In private gardens it does not matter so much if people indulge their fancies as regards eating the green points only; but in market gardens it does make an essential difference to the grower, whether he blanches his Asparagus or not, because in that way he adds to the size and length and weight of the saleable portion of his produce. Some may say that this may suit him, but not the consumer. The answer of the best cooks, good judges, who have fairly tested the subject, is that the flavour is best and most delicate when the Asparagus is blanched almost to the top—is blanched, in fact, so as to show only the pink top, as is the case with the best French and English Asparagus.

Since writing the above, I have tried *dai'y* for nearly a week samples of Asparagus cut at the same time, and noted a

marked deterioration day by day, the flavour changing towards the fifth day to an offensive bitter one, and very watery. This was English Asparagus of excellent quality, grown at Colchester. The foreign Asparagus is frequently in a worse condition as to age than the above sample, for naturally Asparagus cut in another country, and, perhaps, experiencing the delays of two markets, and afterwards being exposed in a shop, can only be in a condition to mislead as to its quality when gathered fresh. Few vegetables lose their good qualities sooner from exposure to light and air; grown at home, such fine Asparagus would be found all that could be desired in flavour. V.

VEGETABLE MARROWS IN MARKET GARDENS.

I HAVE read the remarks on Vegetable Marrows by "C. W. S." with considerable interest—not only because I see yearly a large quantity raised for market, but also because of the great liking I have for the fruit as a jam-making product. In this locality, where there is less anxiety to secure early Marrows than is found nearer the metropolis, seed is commonly sown in drills at about 4-ft. intervals, of course thinly, seldom earlier than the middle of May. If plants so raised are later, at least they are more firmly established, and growers hold that fruit is produced earlier on such plants than upon those planted out from frames. That the soil is not so rich as is found in beds fully prepared may lead to this result; but, the plants being thicker, the quantity of fruit per rod is not less, whilst the attention required is but little. It is not unusual to see Runner Beans sown wide, and rows of Marrows between them. Of course, whether the seed be sown in drills or dibbled in in hills at 4-ft. intervals, rows are still produced. It is so easy to save a large quantity of seed, that at sowing-time it is seldom spared. A thick plant, if it escapes the slugs, can soon be thinned; but a thin plant is not so easily remedied. With that conservative unreason that so thoroughly characterises the Londoner, the Long White Marrow is almost the only kind that can secure a sale, and if this be of the ribbed form so much the better. In the matter of flavour and productiveness, some of the green kinds excel the Long White, but, good as they may be, it is useless to grow what the public will not purchase. The comparatively early stage at which the fruits are cut for market affords early and most useful relief to the plants, and thus the produce is far in excess of that obtained from plants that have to carry two or three large fruits on them for seed. For the production of preserve, or, to call it by its more homely designation, jam, the Vegetable Marrow stands unrivalled. It can be relied upon to produce a crop of fruit at the very cheapest rate when all others may fail. The white-fleshed Marrow naturally produces the palest jam, but the flesh of the darker kinds, and especially that of the Ohio Squash, not only produces the richest colour in the preserve, but also the best flavour. To make good jam the fruits should be well matured, but not ripe; that is, they should be fully grown, but the skins should not have begun to harden—then the flesh is solid and contains the least proportion of water. Much depends upon the making, but that is, like all cooking, a matter of culinary experience. When well made it is, without doubt, one of the pleasantest and most wholesome of all preserves. A. D.

EARLY AND LATE PEAS.

NOTHING in the vegetable way shows the backwardness of the spring more forcibly than the Pea crop, for while in ordinary seasons we always gather Peas at latest by the end of May, they will have to come on fast if we get any much before this month is out, although sown and treated in the ordinary way, and nursed on in a warm sunny border. There is, however, every promise that Peas will be in great abundance by-and-by, as I never remember to have seen them more vigorous and healthy than they now are. This is owing to the heavy rains which we have had and the few days of real growing weather between the rainfalls, conditions that just suit Peas, and most vegetable crops, all of which are now growing most satisfactorily. In regard to Peas, it should be borne in mind that although they soil so well now, a week or two's strong sunshine may so dry the soil as to bring on mildew, a pest which, when once it gets hold of the leaves, is fatal to the bearing properties of the plants. Nothing tends to ward this off so well and keep the plants in health as mulching the sides of the rows heavily with stable manure, which not only keeps the soil cool, but prevents in a great measure the escape of moisture. In light shallow lands it is next to impossible to grow good Peas without mulching, for should they be watered it is of little use, as before the water has time to soak down the dry, heated air

draws it out, and leaves the roots that it attracts near the surface famishing more than before.

For early and mid-season crops I am averse to the use of manure, as I find that it induces the plants to make too much haulm, but for those expected to yield a supply till late in the autumn, some stimulant of this kind is necessary, as it is surprising the difference there is in vigour between those sown now and others that have been put in up to this time. To make up for this deficiency of strength, they must have something extra on which to feed, and this is, perhaps, best afforded by digging and preparing trenches after the manner of those got ready for Celery, except that after they are finished, they should be to a greater extent filled in, so as to leave them only about 2 in. or 3 in. at most below the general ground level. This will be sufficient to admit of flooding them with water when necessary, which, if they are expected to bear well, will be often after they get into bloom and begin to show pods, as that is the time when their energies are taxed most, and, to save exhaustion, every pod should be picked when ready, whether the Peas may just then be required or not, the maturing of seed being a great drain on the plants. After trying many kinds for late sowing, I find none better in quality, or more productive, than the old British Queen, which all through the summer and autumn is a Pea of sterling merit, and one that may be always relied on. This and the Ne Plus Ultra are the only two tall kinds that I care about, and, although they have been in cultivation a great many years, they are still unsurpassed. S. D.

THE FLOWER GARDEN.

Haberlea rhodopensis.—At pp. 375 and 430 of THE GARDEN a description is given of this very interesting plant, which we believe will prove to be one of the very best of recent introductions amongst hardy rock plants. As we have grown this little gem for several years on our rockwork, a hint or two as to its successful cultivation may not be unacceptable. We have treated this plant in the same manner as the Pyrenean Ramonda, i.e., we have planted it on the north side of the rockwork; therefore the sun never directly reaches it. We grow it in fibrous peat, and fix the plants, if possible, into the fissures of the rockwork, so that the rosettes which it forms hang in an oblique position, just as they do in their native country. It succeeds well in this way; but if no rockwork be at hand it may be grown equally well on the north side of a Rhododendron bed. We have it thus situated quite close to a stone edging, a way in which we also grow the Ramonda, and the Haberlea flowers profusely every year in May and June. Established plants will produce from six to seven flowers on a stalk, and form quite a lovely bouquet. The evergreen leaves are of the same firm texture as those of the Ramonda. The plant is very hardy, having withstood our often very hard winters without any protection quite unharmed.—OTTO FRÖBEL, *New Munster Nurseries, Zurich.*

Narcissus pumilus (pp. 338 and 430).—The plant figured by Herbert in his "Amaryllidaceæ" under this name is very small, and may possibly be a starved form of *N. minimus*, the smallest of all the Daffodils. It is certainly not referable, as a garden plant, either to *N. minor* or to its broad-petalled form *N. nanus*, both of which bear flowers three or four times as large. The *N. pumilus* of Redoute's "Liliacæ," t. 409, is a small Grass-leaved plant bearing a solitary white flower, and is supposed to be a variety of *N. dubius*. Mr. Williams' plant is doubtless either *N. minor* or *N. nanus*, which have bright and effective flowers, and bloom early, as does also *N. minimus*, albeit a much smaller plant. If Mr. Williams has *N. cernuus* and *N. moschatius* true, they are readily distinguishable; and if grown in masses the distinctions are still more apparent. Apart from size and colour, *N. moschatius* never produces double flowers, while of *N. cernuus* there are two distinct double varieties.—B.

Herbaceous and Alpine Flowers at Manchester.—Herewith I send you a list of the thirty-six plants to which the first prize was awarded in this class at the late Manchester show. It is difficult in great exhibitions, like that in question, to find a suitable place for these denizens of the valley and the mountain; nor can I say that the site chosen for them at Manchester was a happy one. The Pansies and Violas in particular were placed on the ground as an edging to groups of large plants, and were, in consequence, almost in obscurity. Among the plants shown by Mr. Brockbank, I noticed a very dwarf and unique specimen of the old *Trollius europæus*—quite a miniature compared with the type. *Meconopsis Wallichii* and *nepalensis* were in excellent condition, but not fully developed. There was also a large mass of the new and beautiful *Saxifraga Wallacei*, a kind seemingly intermediate between *S. Mawi* and *S. ajacifolia*. I need scarcely add that those

who would exhibit thirty-six herbaceous plants on a given day would have to grow nearly sixty, and I was told the reserve in the case under notice was equally interesting as those exhibited. The following are the names of those shown, viz., *Meconopsis Wallichii* and *M. nepalensis*; *Saxifraga Crotedolus*, *S. pyramidalis*, and *S. Wallacii*; a beautiful incrustated *Saxifraga*, probably incrustata, erroneously named *S. serratifolia*; *S. lantoscana*; *S. atropurpurea*; *Aquilegia vulgaris*, a fine dark variety; *A. Skinneri*, true red and yellow; *Lithospermum prostratum*; *Trollius napellifolius*, *T. altaiacus*, *T. oreopaeus nanus*; *Orobis vernus*; *Primula amena lilacina*, *P. a. magenta*, *P. japonica* (a fine pan), *P. luteola* (beautiful); *Dodecatheon Jaffrayanum*; *Polygonatum giganteum*; *Symphytum variegatum*; *Cypripedium spectabile*, *C. acule*; *Iberis gibraltaria*; *Lychnis alpina*; *Myosotis Warleigh Surprise*; *Sempervivum montanum*; *Caltha palustris* (double); *Doronicum caucasicum*; *Funkia alba marginata*; *Trillium grandiflorum*; *Claytonia sibirica*; *Phlox setacea*; *Convallaria majalis striata*; and *Ranondia pyrenaica*, a fine mass.—THOS. WILLIAMS, *Ormskirk*.

Arnebia echioides.—The Borage-worts afford us some of our handsomest border flowers, and the subject of the accompanying illustration, though not so showy as some kinds, is certainly amongst

Arnebia echioides.

the most remarkable. It grows about 1 ft. high, and has lance shaped leaves from 8 in. to 10 in. long, covered with short, dense hairs. The flowers, which are of a bright primrose-yellow, have five black spots on the corolla, which gradually fade to a lighter shade, and finally quite disappear. It is perfectly hardy, and succeeds either on the rocky or in a well-drained border, and apparently prefers partial shade. It is a native of the Caucasus, Northern Persia, &c., and, though it has been introduced some considerable time, it is still amongst the rarest of our cultivated hardy flowers.—W. G.

The Woodruff (*Asperula odorata*).—This interesting British plant, with white-scented flowers, produced usually in May, but, like all other plants, later than usual this year, is well adapted for planting at the foot of such trees as *Arbor-vitæ*, or other evergreens, in order to furnish the bare ground commonly seen at their base. Its flowers have a scent somewhat like that of new-made hay, and if cut and dried, the plant is said to be a preventive of moths in woollen and other fabrics. The plant is easily increased by division of the root when growth begins in spring.—E. HOBDAV.

Time for Re-potting Ariculas.—I feel sure that all Aricula growers will join me in thanking the Rev. F. D. Horner for his very interesting note of last week, and will now feel quite safe in following Mr. Douglas in the advice he gave as to early potting. At the same time it is evident that there are two opinions, and it will be interesting to note the results if Aricula growers will keep a record of their experiences for future use. We commenced re-potting ours only on Monday last, so the whole stock will be late

potted this year. I shall keep a careful record of the results.—BROCKHURST.

TREES, SHRUBS, AND WOODLANDS.

RHODODENDRONS AT CAIRNSMORE.

At the very foot of the huge mass of granite, 2300 ft. high, which bears the name of Cairnsmore of Fleet, lies the pleasant, well-wooded park which surrounds the house of Cairnsmore, the residence of Major and Mrs. Colvin Stewart. It would take a large space to describe the charms of the park and pleasure grounds, musical with running water and the song of birds. Yet soft and rich as are the changing scenes within little more than a stone's-throw of the house, the visitor is not allowed to forget that he is in a sub-alpine region. For even should the impending mountain, with its grim precipices, deep glens, and purple moorlands be for the time hidden by the thick foliage, at every turn there are to be seen huge monoliths of granite, sometimes so long and slender as to be used where usually poles or posts would be employed, as, for instance, in the hay-shed, the roof of which is supported by granite pillars about 14 ft. high; and in the glen there may be seen a light bridge thrown airily across the burn from crag to crag, which, on closer inspection, turns out to be a single gigantic plank of granite.

But the specialité of Cairnsmore are the Rhododendrons. For many years Major Stewart has been an enthusiastic cultivator of this delightful shrub, and as the climate, moist and mild (like all the west of Scotland), and the soil (granite débris mixed with deep peat) are all that could be desired, the amplest success has rewarded his efforts, and he is now the owner of probably the finest specimens, if not of the largest collection, in the south of Scotland. The lodge is approached by a long drive through a glen, down which rushes a mountain stream through a rough wood where have been planted many hybrid Rhododendrons which promise, when more air and light is given them, to form a woodland scene probably unique in this country. On entering the lodge gate, the first thing that arrests the eye is a magnificent bush of the Cairnsmore Scarlet, a seedling which is said to have been raised there about thirty years ago, and which retains much of the arborescent habit of the Indian *R. arboreum*. This bush overhangs the approach, is 15 ft. high, and loaded with bloom. In pleasing contrast is a large bush of Cunningham's White, which makes up in quantity what is lacking in quality of the trusses. Passing along the approach, may be noticed on the right, at some little distance, a long border surrounding the garden walls filled with thriving Rhododendrons, of which there is something to be said presently. Some fine bushes of limbatum, loaded with Cherry-coloured blooms centred with white, next attract attention, and a little further on is a display of colour which for freshness and richness the writer does not recollect to have seen equalled. An immense bush of the Cairnsmore Scarlet, about 17 ft. high, absolutely crowded with brilliant blossom, is placed in striking contrast with a large double white Cherry. The contrast is so exquisite, backed up as it is with the tender green of a giant Beech, that most people would feel rewarded for a very long journey by this sight alone. But there is a great deal more to see. Returning to the long border round the garden walls, the visitor is introduced to some of the choicer varieties. The Major has for years been working plants upon their own roots, on which he finds that, unlike Roses, they are much more robust than when grafted. From these plants round the garden walls he has obtained a great quantity of layers.

Perhaps the first blooms to catch the eye are those of a true scarlet, which came to Cairnsmore years ago misnamed Louis Philippe, but which is quite unique in colour, being indeed truly scarlet. This is now called the Major, and if it finds its way into the market under that name, is worth looking after.

An exquisite white flower, with a quantity of dark purple spots, named George Cunningham, and sent out by the Lawson Seed Company, is worthy of special attention, as the flowers are quite distinct and the foliage excellent. Among the young plants which have not yet bloomed at Cairnsmore one is struck by the vigorous growth and immense leaves of W. H. Punshard (Waterer), and the neat foliage and compact growth of Lady Ilchester. Lawson's Sikkim hybrid Thomsoni is a free bloomer and very pretty; Sun of Austerlitz, a fine carmine and of grand habit; Verschaffelti, rosy-white with dark markings; Broughtoni, with handsome leaves and bright rose flowers; Altacrense, full of crimson bloom; atrosanguineum, of a fine blood-crimson; Auguste Van Geert, with immense heads of a cherry colour, and a beautiful unnamed sort, garlanded with rosy blooms in great profusion, were at the time of the writer's visit the principal varieties in bloom, but a great many other sorts were to follow, which have been delayed beyond their usual time by the ungenial season. A walk round this collection does more to convince the visitor of the mistake usually made in planting masses of the common *Rhododendron ponticum*, to the exclusion of these far more beautiful and interesting varieties, than pages of writing. Another irresistible conviction to which one is led is the superiority of plants on their own roots. Peat is accessible in many places, but pure peat out of a Scotch Moss will not grow American plants. It must be mixed with an equal proportion of sharp sand, the coarser the better. Sea sand, if it is coarse enough, does perfectly well, and a little good manure at time of planting does wonders to help robust growth. Even where peat is not available, *Rhododendrons* will grow and flower well in good loam not approaching to clay or chalk. They should, however, be supplied with manure and leaf-mould mixed with sand in order to become established. One more word: Let them not be exposed to cold cutting winds in winter, or to the full blaze of sunshine in summer. The former destroys the foliage, and the latter burns up the blossoms of many delicate kinds, and thus shortens the flowering period. In choosing a spot for choice *Rhododendrons*, let the winds be broken by surrounding but not overhanging trees or adjacent buildings; let the sun have frequent but not unbroken access, and let the ground be thoroughly drained before preparing the beds.

I cannot close my notes upon the Cairnsmore *Rhododendrons* without noticing a very remarkable circumstance in connection with them. The pyramids of blossom seem to have the property of attracting all the queen wasps for miles around, and Major Stewart has a very ingenious and thoroughly effective means of destroying these. A strong india-rubber band is secured by a string about 3 ft. long to the wrist. Armed with this, the sportsman, for so he may be termed, waits till a queen wasp settles on a *Rhododendron* (and on a sunny morning he has not long to wait), when, taking a steady aim, he fires the india-rubber band off the thumb of the left hand, and rarely fails to knock the wasp senseless on the ground. In this way from twelve to twenty queens were secured in one morning during my visit, and that of course represents the destruction in an easy way of so many nests.

SALMONICEPS.

A Beautiful Elm.—Mr. Cole called my attention the other day to a very beautiful Elm in Kensington Gardens, every branch of

which is feathered from top to bottom with young twigs, as if a colony of Ferns had established themselves over the whole tree. It forms a remarkable contrast to the other bare-branched and bare-stemmed Elm trees in the same park. It is a variety of the Dutch Elm, and the curious growth of twigs in question is owing to numerous excrescences developed on the branches and stems.—V.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

The Vanilla Tree.—Some foolish person has been writing a note in the "Times" about tree planting in Paris, as follows: "Any one interested in the planting of squares or boulevards, and with time to spare, would find a trip to Paris well repaid by a view of the Avenue d'Essling, now a mass of purple bloom, which quite eclipses the Chestnuts so familiar in this city. The Vanilla tree, with which that avenue is planted, has very handsome foliage, and would quite stand the London climate, making a pleasant variety and growing rapidly." This has caused many puzzled persons, who only know the Vanilla as a delicate hothouse Orchid, to ask what can be meant. The writer can only mean the common Paulownia, but he is courageous enough to write to the "Times" without taking the trouble to ascertain the proper name of the tree. Of course he also recommends it for use in London, without taking the trouble to enquire how it actually grows there, where it lives, but never makes any such growth or flowers so freely as we have noticed it about Paris. On warm soils in the south of England, and not far from town, it does much better and sometimes flowers freely. The Catalpa is a much better tree for London, so far as we have observed, and both grows and flowers very freely, even in the centre of the town.

Constricted Bark.—This disease is occasioned either through the action of the roots becoming too feeble for the proper support of the tree, or through very dry cold air playing upon the trunk and branches of a tree which has become exposed. It is occasionally shown by the bark becoming indurated and losing its elastic properties, whereby the sap vessels get confined and their proper functions suspended. In the Plane tree the outer layers of bark peel off; in the Oak they become torn longitudinally; and in the Beech stretched horizontally. When in this hide-bound state the trunks often become covered with Mosses and Lichens, and are preyed upon by insects. The only sure remedy is scoring the trunk, and perhaps the main branches, right through the bark from the top to near the roots. The operation may be safely performed about midsummer, and the relief given to the tree will become apparent directly. We have seen old Apple trees renovated by scraping or stripping off a considerable portion of the rough old bark, and hide-bound young ones instantly revive after scoring. By leaving the inner layers of bark uninjured, considerable liberties may be taken with the rough external coating.—A. J. B.

Canker in Timber Trees.—This disease, though more frequently found upon fruit trees in orchards than amongst timber trees, sometimes attacks both the Elm and the Ash upon very wet soils, the drainage of which is imperfect. It is more especially found in low situations, where there is not a free circulation of air. It may also arise from an unwholesome substance in the soil, or being lodged in the vessels of the young shoots, causing blisters near the buds, and at the bases of larger branches. The parts affected are generally chosen by insects, whose larvæ keep the diseased spaces open by feeding upon their margins. It is not unusual to find fast-growing trees in the above situations attacked by canker. The only effectual remedies for the disease seem to be good ventilation by means of open cuttings or rides in the woodlands, and thorough drainage.—A. J. B.

Lilacs.—These are now doing so much to relieve the ugliness of many parts of London, that one regrets that the many beautiful kinds grown in Continental gardens are not also grown here; and it is to be regretted that the Continental way of pruning the Lilac bush, that is to say, thinning out the shoots so as to induce a stronger bloom, is not carried out with us. The tendency of the Lilac to ramify into a number of small shoots frequently causes some of the varieties to produce very small flower-shoots, which a little judicious thinning would remedy. There are surely no shrubs more worthy of our attention than the different kinds of Lilac.

Hardiness of Emborrhium coccineum.—It may interest the readers of THE GARDEN to know that two fine specimens of this plant have lived through the late severe winter, and are now flowering well. I have lately measured both; one is quite 20 ft. high and 8 ft. through, and is flowering freely; the other is in the American Garden, which is in lower ground and in a less dry position; consequently it lost the chief portion of its leaves during the winter, but the wood is uninjured. It is 25 ft. high and 16 ft.

through, and as every twig is bearing flowers it resembles a mass of fire. Such trees as these are worth a long journey to see.—SAMUEL HORSMAN, *Combe Royal, Kingsbridge, Devon.*

Cerasus Rhexi.—Let me strongly recommend this shrub to the attention of your readers. It is one mass of bloom, and the most striking object I have seen for a length of time.—A. R., *Bromley.*

IDESIA POLYCARPA CRISPA.

ALLOW me to direct attention to a curious case of dimorphism which has appeared in two plants of the *Idesia polycarpa*. The general form of the typical *Idesia* is too well known to need mention; we shall, therefore, content ourselves with figuring and describing the monstrosity in question. This remarkable variation appeared for the first time at the Museum of the Garden of Plants in Paris in 1875 in a plant of about 8 ft. in height and in a single shoot. In the following summer another plant, stronger than the first one, produced two shoots, which were identical with the growths of the previous year. In 1878 several other plants developed similar shoots; it is probable, therefore, that this variation may become permanent. The following is the description of the variety of which we are speaking: The shoots are denuded at the base, somewhat twisted out of shape, with uneven surfaces, showing elevations and depressions here and there. The leaves are of different shapes and sizes, with long leaf-stalks, and frequently reach a length of from 4 in. to 8 in., and even longer. The whole of the leaf is corrugated and twisted irregularly, the veins and nerves being whitish.

The leaves of the variety consequently form the strongest possible contrast to the smooth, regular, well-shaped leaves of the parent plant, the monstrosity being made all the more remarkable by the shoots bearing normal and abnormal varieties of leaves growing on the same stalk. Practical men will tell us that this transformation is the result of an accident, while, on the other hand, botanists will say that it is an anomaly. These methods of accounting for the fact, although apparently sufficient, are in reality worse than insufficient, seeing that they simply put the difficulty on one side instead of solving it. The reflective mind, on the other hand, asks itself whether any of these changes of character in plants can be called accidents. Are not all those phenomena, which we call abnormalities, accidents, and anomalies, just as much governed by natural laws as those which we call normal? If we call such phenomena accidents, why should we not apply the same term to the thousands of varieties which are constantly being discovered amongst seedlings? Are not the latter phenomena analogous to the former? We commend these observations to the attention of vegetable physiologists.

Whatever may be the cause of this curious variation, the plant of *Idesia polycarpa crispa* is none the less interesting to both horticulturists and botanists. The *Idesia polycarpa*, which was formerly also called *Polycarpa Maximowiczii*, was, at the time of its introduction from Japan, much vaunted as a fruit tree, an idea which still obtains amongst cultivators. It does, indeed, bear fruits, botanically speaking, but, instead of being good to eat, they are, on the contrary, dry, hard, and disagreeably bitter.

E. A. CARRIERE.

A PUBLIC NURSERY.

THERE is no more pressing want for our public parks and gardens than a good nursery on ground belonging to the State and in pure air for the main supply of the trees and shrubs now required in the public parks and gardens of London and its neighbourhood. We find the following not very hopeful reference to this subject in an article on this subject by Lord Henry Lennox in the current number of "Time": "I am one of those who are strongly of opinion that we ought to have a nursery under the management of the Office of Works in which to raise both trees and shrubs. It is, however, fair only to add that in this view I have the misfortune to differ from no less a personage than my distinguished friend Sir Joseph Hooker, the director of Kew Gardens. Sir Joseph considers that, while it is certainly cheaper for the nation to raise its own bedding and fine-foliated plants, it is better to buy trees and shrubs when they are cheap, and at sales in the country, because he considers that the demand for the latter is intermittent. It is exactly on this point that I venture to differ even from so eminent an authority." One of the many reasons which it seems to us should lead to the establishment of a public nursery would be the purchase of trees and shrubs of desirable kinds which it is impossible to get at ordinary sales. If the parks of London are to be planted in a fitting manner, the stores

from which they are supplied should be removed from the fluctuation and very narrow limits of the ordinary sales of common shrubs and trees. They ought, indeed, to be independent of the fashion of the day. There should be represented in them all the fine northern trees of the world, and, as we know too well, comparatively few of these are obtainable in most nurseries, many of them not obtainable at all. Thus, for example, there are various American trees which are never seen in a nursery, and when rare trees are seen elsewhere they are not obtainable. To a properly organised nursery for supply

of the parks of London people from all parts of the world would be happy to send seeds and young plants, and we should be able to get up a splendid collection of the hardy trees of the northern world, and these not as single specimens, but as healthy young stock for distribution amongst the various parks in positions most suitable for them. The very cheap common trees and shrubs might be obtained at sales, no doubt, but not the rare and good things. Our nurserymen would be very glad to contribute to or exchange with such an establishment, which could not fail to have a beneficial effect on the tree culture of this country.

Nursery Convention.—The fourth annual meeting of the American Association of Nurserymen, Florists, Seedsmen, and kindred interests is appointed to be held at Cleveland, Ohio, commencing Wednesday, June 18, and continuing three days. Among the objects sought by this association are the following: The exchange and sale of nursery products, implements, and labour-saving devices; the exhibition and introduction of new varieties of fruits, trees, plants, &c.; the cultivation of personal acquaintance of others engaged in the trade; to perfect better methods of culture, grading, packing, and avoiding needless exposure of nursery products when in transit; to obtain a reduction in rates of postage on seeds, scions, roots, and cuttings; to avoid the evils of dishonest tree agents; and to prevent the taxing of nursery stock when growing.

Idesia polycarpa var. *crispa* (one-third the natural size).

VEGETABLE CULTURE FOR MARKET.

SEAKALE.—This is extensively grown in the neighbourhood of London, and is considered a much more profitable crop than Asparagus. The demand for it is, however, not so great as that for Asparagus. There are few people who do not like Asparagus, green Peas, and new Potatoes, but there are a great many who do not like Seakale. Large quantities of it are, however, sold in Covent Garden between the beginning of December and the end of March. This is proved by the immense breadths of land devoted to its culture, and the long trenches in which it is forced to be seen in the Fulham Fields and elsewhere. Market gardeners grow Seakale on a different system from that usually practised in private gardens; indeed, if they were not to do so, the crop would be a far less profitable one than it is. Seakale is a crop easy to cultivate and free from disease and insect pests; it gives little trouble, and is highly remunerative. Growers in the Fulham Fields, the Chiswick and Barnes Thames level, the Deptford and Woolwich neighbourhoods, and, in fact, for many miles round the metropolis, pay much attention to it, and consider it one of their best vegetable crops.

Some growers raise Seakale plants from seed, but the majority propagate them from root-cuttings. It is, however, advisable once in every few years to raise plants from seed in order to infuse fresh vigour into the stock. For seed sowing, a piece of ground is selected in March and deeply dug or trenched; no manure is applied if the ground had been liberally treated in that respect for the previous crop; 4-ft. wide beds, with 1-ft. alleys between them, are then formed, and on these the seed is sown rather thickly and covered with soil from the alleys or by raking them in. The seedlings are left unthinned and unmoved during the succeeding summer and winter, no care being paid to them whatever beyond weeding. When the plants are twelve months old from the time of sowing, they are lifted, and all roots, except the main ones attached to the crown, are cut off. The main roots are also cut to 4 in. long. These are then planted permanently with a dibble in good soil. The objection to seedlings, however, is that they occupy the ground for one entire year without yielding any return, and also that during the second summer they are sometimes liable to produce a profusion of small crowns; and, unless these are reduced, the plants form but weakly subjects for forcing. The reason why the seedlings are not thinned and planted out the first season is because if so treated the majority of the plants "bolt" during the summer, and at lifting time the roots are weak, and therefore are both troublesome and unprofitable.

The best way, therefore, of increasing Seakale is from the trimmings or cuttings of the fleshy roots cut away from the plants when they are lifted for forcing. These throngs or roots, when removed, are thrown into a heap in a shed, there to remain until all the plantations that are to be lifted for forcing have been dug up and trimmed. The best of the trimmings are then selected, cut up into pieces about 4 in. long, and laid in a heap by themselves, and the remainder thrown away. In January beds are prepared for the cuttings, about 4 ft. in width, any length, and raised 6 in. higher than the surrounding level, to keep the Seakale roots healthy and free from damp. The cuttings are laid thickly on the surface of the bed and covered with soil. At planting time, which is in March, the beds are uncovered, when the roots will have formed several eyes, all of which are rubbed off, excepting the strongest top one. Some growers do not cut the roots until planting time, but lay them on the beds as selected from the shed. In March, when the beds are uncovered, they select the best eye, then cut the roots at the

required length below it, and rub off all other eyes, as in the previous case. The Seakale cuttings, being thus prepared for planting, are inserted with iron-shod dibbles into ground which was well manured and deeply dug or trenched in winter, levelled in February, and lines drawn along it 3 ft. apart and planted with Cauliflowers, keeping them at the same distance asunder in the rows. Between the lines of Cauliflowers, other lines are drawn precisely in the middle, and in them are planted white or green Paris Cos Lettuces 18 in. apart. In the rows occupied by the Cauliflowers, too, Lettuce plants are inserted alternately. A Seakale plant is now placed alternate with the Lettuces and Cauliflowers, but in the same lines. The Lettuces are first ready for market, and are removed before they injure the Cauliflowers. By the end of June all of the latter crop is also marketed, leaving the Seakale, which by this time will be coming up strongly, in sole possession of the soil. Some growers plant Seakale sets 15 in. by 18 in. apart amongst spring Cabbages, which are all removed before they can materially injure the Seakale. Others plant them between Asparagus ridges; but in this case they must all be lifted at the end of the first season, as is also the case when they are planted between fruit bushes and Moss Roses. Some market gardeners who grow roots for sale plant their sets at 18 in. apart each way, and never intercrop the ground amongst them, but take great care of them; and, under such management, they get finer roots than those produced among other crops. No care is necessary among Seakale plantations throughout the summer and autumn beyond frequently hoeing the surface soil, cutting away all flower-spikes, and rubbing off all small shoots that may chance to spring around the main one.

When forcing-time arrives, if the field is to be kept to yield what is termed "natural" Kale, *i.e.*, without being forced in any way, every third row of roots is lifted as required for forcing, and thus the rows are left in pairs with a space of 3 ft. between them. The surface of the soil is then raked clean, and from this wide space the rows are earthed over to the depth of 6 in. to prevent the frost penetrating the ground amongst the crowns and thus rendering it cold and late. The Kale begins to push about the second week in March, and, according to the position of the field and nature of the soil and weather, a supply may be gleaned therefrom till the end of April. As soon as the point of a shoot of Kale is discerned above the ridge the head is fit for cutting. For early forcing, the very best crowns, and such as the leaves die away from earliest, are selected and trimmed, so that 4 in. or 5 in. of the main stem, with the crown on the top, only remain. These are then placed closely together in an upright position in a hotbed prepared for starting them in, which, in the case of the earliest batch, consists of a manure-bed covered with frames and sashes, and a few inches deep of soil levelled within the frames for planting the roots amongst. A heat of 65° or 70° is kept up inside the frames, if possible, by applying hot linings of manure and by placing litter or mats on the surface over the glass, which latter also keeps all dark and blanches the Kale. Seakale growers try to have a good cutting on Lord Mayor's Day; but this is considered too early for regular forcing.

Forcing commences in earnest about the first fortnight in November, and large trenches or beds, on which Cucumbers were grown during the summer, are cleared out and re-filled with hot manure, over which 8 in. of soil is placed, and therein the Seakale is planted thickly in lines across the bed, which are about 5 in. apart, and about the same space of a margin is left empty on each side. Amongst the roots, and all round the beds, rows of stakes are inserted, 18 in. of their length being left above the soil.

Some 6 in. or 7 in. deep of short litter is then strewn over the whole surface of the beds, which are then covered over with mats supported on the ends of the stakes. Hoops and mats are often used instead of stakes. In about three or four weeks after the beds are made up, cutting begins, when it is necessary to uncover the beds as the operation proceeds, drawing the short litter off the crowns to get at them, and replacing it as speedily as possible, as all the crowns are not fit to cut at the same time. Beds for later crops are prepared on a well-sheltered plot of ground as near home and the manure-heap as possible. The ground is marked off into spaces either 4 ft. or 5 ft. wide, with alleys 2 ft. wide between them. These spaces are used as beds, over which the soil from the alleys is placed, after finely breaking it, until the alleys are 20 in. deep. The Seakale crowns are then all lined into these beds as described in the case of earlier beds, and thus the beds are left uncovered until they are required for forcing; but, as a rule, two or more of them are always being forced, and others started to succeed them. As these beds have no bottom-heat, it is not necessary that they must be immediately covered, as in that case they, being incited at the bottom, would grow, no matter whether their crowns are cared for or not; but, in this instance, having no exciting agent, and being in a dormant state, they await the cultivator's convenience. In forcing them, the alleys between the beds are firmly filled with fermenting manure, and, the beds being covered as formerly stated, with short litter and mats supported on the upright stakes, all is finished. The Kale takes a longer time to push into growth by this means than when forced on a manure-bed, and it does not come quite so regularly. This method, however, has the advantage of less trouble and risk, and great convenience in keeping up a supply until it can be produced from the open-air beds, after which the forced roots are removed to a heap by themselves, or to the piggery, where their vitality is sure to be destroyed. If conveyed to a field at once, with the manure which formed the beds, and dug in, they would grow again, and prove a future annoyance. The manure being forked out from between the alleys, the soil is levelled, and the piece of ground will then be ready for digging over for French Beans, Cauliflowers, or Tomatoes.

Both forced and natural Kale are cut three days a week, for which purpose is used a small tool with a handle about 1½ ft. long, bent at the neck, and with a blade about 2 in. wide by 3 in. long. This is a handy instrument, and well adapted for its purpose, as it can be so deftly employed for cutting the Kale with a small piece of the root-stock adhering to it. When the day's cutting is over, the Kale is washed, tied in bundles of a dozen heads, placed on its ends in punnets, and again packed into baskets, which are piled on waggons and sent to market. After all out-door Kale is cut, the ridges are levelled down, and the spaces between the rows cropped with white Cos Lettuces. Immediately the Seakale begins to grow numerous crowns are produced; but these are all reduced to two, or at most three, of the strongest, and in this respect, in removing their flower-spikes, and in keeping the soil about them loose and clean, they are well attended to afterwards. These old roots are the principal ones used for early forcing next year.

RHUBARB.—This is an important crop, and the quantities of it sold in spring are enormous. Waggon-loads of it are sometimes sold at very cheap rates, but at other times good prices have been obtained for it. Early Rhubarb is especially acceptable, coming in, as it does, when Apples have become scarce and dear. Rhubarb forcing in market gardens is very simple, and is done in hotbeds covered with hoops and mats. In making young plantations, the sets are sometimes planted about 18 in. apart each way; and, at forcing-time, every

other row, and the alternate plants in the row left, are lifted for forcing; old plantations, too, are cleared entirely for forcing. The leaves will be decayed enough to be raked off by the middle of October, by which time the first portion is usually lifted for forcing. For this purpose trenches are cast out, about 4 ft. wide and 2 ft. deep, and filled with fermenting manure. Over this a thin layer of common soil is placed, and in it the crowns, after being trimmed of some of their rougher roots, are planted. Over the crowns some loose litter is strewn, and then the beds are hooped over and covered with mats, over which another layer of straw or litter is placed during winter. In the outside covering, apertures are made at gathering time, and closed again when done. In February, if the weather be mild, the hoops and mats are commonly dispensed with. In some gardens excellent Rhubarb is produced in pits, with some heating material underneath, and some loose straw merely shaken loosely over the roots. Mr. Yeldham, of Hammersmith, forces Rhubarb in large quantities in his fruit houses; the roots are packed closely together on the floors, a little leaf-mould or other soil is cast over them, and they are afterwards covered with mats, which remain on them until the stalks are fit to gather. Rhubarb forced in this way is not so good in colour as that produced in darker places, and which we see in the markets early in the season; but it is greatly superior to it in flavour, and meets with a ready sale.

Whole fields in Surrey are devoted to Rhubarb culture, but the bulk of it from London market gardens is grown under fruit trees, positions in which it grows well. In spring, when the produce is most wanted, the trees are leafless, and therefore they do not shade it much, but afford slight protection, and the produce comes naturally fit for use about a week sooner than from the open field. The soil for growing Rhubarb is a deep, rich, and moderately moist one; exposed positions decidedly produce the finest Rhubarb, but under fruit trees this crop grows almost as well as anything else that could be planted; therefore, in order to economise this space, few crops probably pay better. The varieties grown consist chiefly of the Early Albert, Myatt's Linneus, Myatt's Victoria, Red Champagne, and Johnson's St. Martin. Red Champagne is much sought after in the market on account of its fine red stalks; and, when forced, its colour is brighter and more imposing than that of other sorts. In making permanent plantations, divisions of the old stools are used, and they are planted in rows 2½ ft. or 3 ft. apart, and from 2 ft. to 2½ ft. asunder in the rows. No leaves are cut away from them the first year, but the space between the lines is planted with Lettuces or Coleworts. During the second season many stalks are not cut, but in the third year a fair crop is realised. As soon as time can be spared in winter, and before the leaves begin to grow, the ground between the rows is dug over roughly, and a large forkful of rank litter placed over each crown. It would be difficult to take the litter into the plantation on a wheelbarrow, owing to the softness of the newly-dug soil; therefore the workmen carry it in baskets. As a rule, people are employed to fill vegetable baskets, others to carry them on their heads, and a few more to empty their contents over the crowns of the plants. Under the litter the stalks come up clean, tender, and crisp—very much more so than if none were used. The leaf-stalks are pulled for market as long as there is a demand for them; and even in late summer large waggon loads are often disposed of to jam manufacturers. In bunching the Rhubarb for market, a piece of board, padded with a piece of an old bag, is nailed to the bench in the packing shed, and into it four nails or pegs are driven, two withies being laid crossways for tying. The finest stalks are placed

in the bottom, the top and ends being alternate, and over them some small ones, making up the outside again with large stalks, so that the small ones are entirely hidden. These bundles are then packed on waggons and taken to market during the night, and in the morning are sold to the dealers either by auction or otherwise.

C. W. S.

NOTES OF THE WEEK.

Fine Tomatoes in Spring.—The scarcity and inferior quality of Tomatoes have lately been very remarkable in Covent Garden. This is to be regretted, considering the way in which the taste for Tomatoes have grown of late years. Frequently inferior, spotted, or half-decomposed fruits that have travelled a long way are offered for sale, and apparently bought and eaten. Three shillings a pound has been the common retail price during the spring; it is therefore clear that our markets are insufficiently supplied, as an abundance of fine Tomatoes could be grown to pay the grower at less than one-half that price. The finest that we have seen for a long time are those that are grown by Mr. Gilbert, of Burgley. The sort which he likes best for winter cultivation is Criterion, inasmuch as owing to a peculiar habit which this kind possesses, the leaves fall down from the stem and the flowers stand erect, so that its fertilisation in winter is very much easier than that of the ordinary kind, and there is a marked difference in the freedom with which it produces fruit compared with the other kinds. It was sent to Mr. Gilbert by Mr. Bliss, of New York.

Tovaria oleracea.—This is one of the most striking hardy plants now in flower in the Kew collection. It is nearly related to *Smilacina*, and, in the present state, is similar to the old *S. racemosa*. The stems in the Kew specimen grow about 1½ ft. high, and gracefully arch, though in their native habitat they are said to attain a height of from 6 ft. to 8 ft. The leaves vary from eight to sixteen, and are oblong and pointed. The flowers are nearly ½ in. across, produced in terminal flat panicles, which attain 1 ft. in breadth, and are white, tinged on the outside with pink, as are also the slender stalks. It inhabits the temperate region of Sikkim, where it is found at an elevation of from 8000 ft. to 12,000 ft. above the sea; it is therefore quite hardy in our climate.

Anthurium Schzerianum Palmeri.—This is the name of a very distinct form of the strikingly showy and now well-known *Flamingo plant*. Its spathe is remarkably large, being about the size of Ward's variety, but differs from it in its not being so broad, but considerably longer. We noticed it amongst numerous other varieties in Messrs. Veitch and Sons' nursery at Chelsea.

Campanula Allioni.—The Rev. Mr. Nelson tells us that this beautiful Alpine Hairbell grows freely and flowers abundantly in his garden in Norfolk. It is a large-flowered dwarf species, and admirably suited for the rock garden, or the front margin of a choice border of flowers. We believe it is one of Mr. Backhouse's introductions, handsome specimens of it having been sent to us last year from the York Nurseries.

Gypsophila cerastioides.—One of the prettiest novelties in the way of Alpines which we have had the good fortune to note of late is this plant, which is now finely in flower at Mr. Parker's nursery at Tooting. It grows about 2 in. high, and has a spreading habit. The leaves are about 1½ in. long and spatulate from the axils, of which are produced small clusters of blossoms, which are ½ in. in diameter, white with a violet streak down the face of each petal, and heavily pencilled with the same colour on the back.

The Lattice Plant (*Ouvirandra fenestralis*).—It is not often that one meets with this singular aquatic plant in flower, but in such a state we saw it a few days ago in Mr. Williams' nursery, where several plants of it are thriving admirably and developing leaves to almost the maximum size. They are growing in large tubs of water, which, in order to keep it sweet, receives a surface-syringing and a small additional supply daily.

The Late-flowering Scillas.—Amongst the numerous kinds of spring-flowering bulbous plants of which we have now choice perhaps none are more universally esteemed than the common Blue-bell (*S. nutans*). Beautiful as it is pure and simple in its wild haunts, it is much more effective when associated with the many-coloured varieties that have emanated from it. The variety *atro-cerulea* is desirable on account of the rich deep tint of its bells, and it forms a pleasing contrast to the pure white-flowered form which, too, is distinguishable from a large-flowered kind, and one of dwarf habit called *nana*. Then, again, there is the rose or rather violet-coloured

form, which varies in intensity from a deep to a lighter hue. The Spanish Squills, or *S. campanulata*, are similar to the foregoing, and have equal variation in point of colour, but they are considerably larger in every part, and the bells are more spreading. In this group one or two superb varieties are especially noteworthy, viz. *Empress*, a kind with unusually large blossoms, white, lined with blue; and *Emperor*, a variety having a porcelain tint, also streaked with blue. These, too, have very characteristic foliage, being much broader, flatter, and of a deeper green than that of the ordinary forms of these Squills. Of these a beautiful display may now be seen in Mr. Barr's nursery at Tooting, where they are planted in large masses, and in close proximity to each other, so that there is a charming blending of colours. For the ordinary border Squills cannot be too strongly recommended, as they are easily grown, and they never fail to produce a good crop of blossoms, which are admirably adapted for cutting, a state in which they last for a considerable time in perfection. Their most natural position, however, is as undergrowth in woods, &c., and also in the wild garden, where they well repay the trouble of naturalising.

Flowering Trees in the Parks.—The parks of London are now beautiful with flowering trees, and the air sweet with their fragrance. In this respect the gardening in the London parks is more successful than in any others, mainly because trees are let alone and allowed to assume their natural forms. The most that one can wish to be done for them is thinning them out and opening them up a little here and there. We notice with pleasure that this has been done very tastefully in Kensington Gardens by the edge of the Serpentine. By thinning the trees and letting the turf spread among them here and there much improvement has been effected. Something of the same kind may well be done by the Long Walk, which is now very beautiful. Many rare trees and shrubs there will be all the better for being protected from over vigorous neighbours. One of the tasks which both hybridisers and collectors might well set before them is that of obtaining for us later-flowering trees and shrubs. One must regret that the glorious bloom of the real summer trees should so soon fade away, and in many gardens not be followed by any succession of blooming trees. To secure late-flowering varieties of the real summer ones would be most desirable. Still more so should we aim to obtain and give good places to late-flowering species.

Rare Hardy Flowers from Zurich.—We have received from Messrs. Fröbel & Co., of Zurich, specimens of the beautiful white-flowered *Ramondia* (*R. pyrenaica alba*). Its blossoms are, however, not quite white, but are suffused with a delicate bluish tint, and are furnished with a central orange-coloured ring. It is a charming acquisition to our list of rock plants. Associated with it was *Nigritella Heuffleri*, a kind in the way of *N. angustifolia*, but with flowers of a much brighter colour, resembling both in form and colour the crimson ones of the common *Trifolium incarnatum*, except that the flower-hues are shorter. The white-flowered variety of *Omphalodes verna*, also in the same collection, is a pretty addition to early spring-flowering Alpines, and another pretty plant which accompanied it was *Orobis formosus roseus*, which produces an abundance of blossoms of a deep rosy tint when first expanded, but which afterwards change to a bright purplish-blue.

The Trees and Shrubs in Victoria Park.—The effect of the foliage of the trees and of the flowering shrubs in Victoria Park is now remarkably beautiful. Nothing is more agreeable at this season than wandering about in the noble parks, which are now happily open to us, in London, and seeing the flowering trees in all their glory of bloom, and finding out the rarer kinds and finest specimens. No effort hitherto made in gardening has had so good a result as that of planting hardy flowering trees, and it should encourage the superintendents to turn their attention more and more to this subject, because of the permanence and the value of the results obtained. Little schemes of garden and temporary decorations are naturally short lived, no matter what we do; but the planting of fine flowering trees Londoners will have reason to be grateful for for many years.

Carolinea elegans.—A handsome stove shrub bearing this name is now in flower in Mr. Bull's nursery. It has an erect habit, and digitate leaves similar to those of a Horse Chestnut, the leaflets being more leathery in texture, and of a deep green hue. The flowers are produced singly from the axils of the upper leaves, and are from 6 in. to 8 in. in length, of a yellowish tinge outside, and covered with soft whitish down. The most attractive point is the red colour of the stamens, which are numerous and nearly as long as the petals. Like all the other kinds of *Carolinea*, it is a native of the Tropics of the New World.

New Pelargoniums.—Mr. Hawkins, of Twickenham, is now sending out two very beautiful Pelargoniums—the semi-double *Vesta*, and the beautiful double rose *Madame Thibaut*—both excellent kinds. Likely to be very popular.

New Dwarf Phloxes.—These bright little flowers are now very beautiful in Mr. Nelson's garden at Aldborough. Mr. Nelson has raised a considerable variety of colours from Phlox subulata. Any new varieties will of course be very welcome in the case of such a favourite plant, which we only know hitherto in the pink and the white form. It would be interesting to know if there are many varieties where the plant is common in America; if not, our American friends will have to come to us for these.

Saxifraga Wallacei.—In the note (p. 442) in reference to this plant we omitted to mention that it was a seedling, sent out about two years ago by Messrs. Dicksons & Co., of Edinburgh, to whom a first-class certificate was awarded for it by the Royal Caledonian Horticultural Society last year. The above name was given to it on the suggestion of the late Mr. James M'Nab, who as well as other competent authorities, considered it distinct from any other kind in cultivation.

Muscari armeniacum.—This is one of the handsomest of all the Grape Hyacinths, and the beauty of it is considerably enhanced by its flowering at a period when most of the other kinds are past. Its flower-stems grow 8 in. high, and are terminated by a dense raceme from 3 in. to 4 in. long, of bright dark-blue flowers, with small whitish teeth. The foliage is much the same as that of the ordinary M. racemosum. It is now in full beauty in Mr. Parker's nursery at Tooting.

Tabernaemontana Camassa.—A highly desirable stove shrub under this name is now in flower in Mr. Williams' nursery at Holloway. It has a neat compact habit, being 1½ ft. high, and has glossy Laurel-like leaves of a bright green tint. The flowers are in terminal clusters of about half-a-dozen; they are double, pure white, and much resemble those of a Gardenia, for which they might be advantageously substituted, their fragrance being similar; being to some extent freer both in growth and flower, this plant is indeed preferable to a Gardenia, and therefore deserves to be better known.

Cymbidium Parishii.—This rare and beautiful East Indian Orchid is now in flower in Mr. B. S. Williams' nursery at Holloway. In habit it closely resembles the superb C. eburneum, and its flowers are also about the same size, but differ materially in the colour of the lip, which in this is copiously spotted and mottled with a deep rose tint on a white ground, and also a tinge of lemon. The waxy, pure white consistence of the sepals is the same, and the delicious aromatic perfume exhaled by the blossoms is not less powerful than that emitted by its better known congener.

Trichocentrum tigrinum.—This exquisite little species is amongst the rarest of Brazilian cultivated Orchids. It is a stemless and bulbless epiphyte, with leaves very similar to those of Oncidium Lanceanum in form and markings, but considerably smaller. The flowers are large for the size of the plant, and have sepals of a yellowish ground colour beautifully barred with rich chocolate. The lip is unusually large and wedge-shaped, with the lower half pure white and the upper of a deep rosy hue, surmounted by a golden crest. The perfume is delicious and very powerful. It is now finely in flower in Mr. Williams' nursery at Holloway.

Astragalus adsurgens.—This is one of the brightest flowered of the numerous kinds of Astragalus grown at Kew. It is not more than 3 in. high, its leaves being composed of about a dozen pairs of leaflets, which are covered with a hoary substance. The flowers are produced in dense heads, 1½ in. across, and are of a deep purple-magenta. This, and the beautiful Hedysarum humile previously mentioned and still in flower, are amongst the most desirable of the dwarf Leguminous plants used for adorning the rock garden.

The "Times" on Mr. Marnock's Portrait.—The "Times" critic of the pictures of the year in the Royal Academy says of this: "Robert Marnock, Landscape Gardener" (1951), by T. Blake Wigram, is one of the most masterly and thoroughly truthful and vigorous portraits of the year, without any sacrifice of delicacy and finish to force. The picture will bear near as well as distant view. All the rest of Mr. Blake Wigram's portraits are eclipsed by his 'Robert Marnock.'"

Elæocarpus dentatus.—One of the most interesting and beautiful plants now in flower at the Pine-apple Nursery is this greenhouse shrub. It is about 5 ft. high, and has small lance-shaped slightly toothed leaves, from the axils of which, and also from leafless nodes, are produced clusters of pretty white bell-shaped blossoms, beautifully fringed round the margins similar to those of the Alpine Soldanelles, and highly attractive.

Saxifraga squarrosa.—This charming pigmy Alpine is the smallest of the Crustaceous section of Saxifrages which we have in cultivation. When not in flower it looks like a Lichen when not closely observed, but in flower the hoary mass is studded with small white blossoms, which have a very pretty appearance. It is now in flower in Messrs. E. G. Henderson's nursery, Pine-apple Place.

Ipochroma longiflora.—This rare and handsome Solanaceous shrub is now flowering in the temperate house at Kew, and is very desirable for greenhouse culture. Its blossoms, about half-a-dozen in number, are produced in terminal, drooping clusters; they are from 2 in. to 3 in. long, tubular, 1 in. across the mouth, and of a bright violet-purple colour. The leaves are ovate and pointed, and are covered with a downy substance on both surfaces. Like all the species, it is a native of South America.

Exochorda grandiflora.—This highly ornamental shrub has produced its large white blossoms abundantly during the past few weeks on the walls at Kew. It is a fine species, and one which cannot be too highly recommended for general culture. A good idea of its beauty may be gleaned from a coloured plate given in THE GARDEN (Vol. XI., p. 152).

NOTES ON HARDY PLANTS IN FLOWER.

Kew.—The collection here is now well worth a visit, though the late season has considerably retarded the flowering period of the majority of the plants. Amongst those of special interest may be mentioned the Black Sarana Lily (*Fritillaria kamschatcensis*), which, though far from being a novelty, is not often seen in flower, but which, from its peculiar aspect, is highly desirable. It grows about 9 in. high, and the leaves are arranged in whorls of four. The flowers, borne three or four in number, are over 1 in. across, cup-shaped, and almost black, the inside shining with a metallic lustre, relieved by a tuft of golden stamens. It is a native of Eastern Siberia, Kamschatka, &c. *Ourisia coccinea*, represented by a fine example, is flowering freely, its bright scarlet blossoms being very attractive. Near it *Pentstemon Scouleri* is producing pretty lavender-tinted flowers. The hardness of this plant has now been thoroughly tested, as it has withstood the past winter quite unprotected. *Reseda glauca*, though not at all showy, is an interesting species, the leaves of which are narrow and very glaucous. The finest of the Borage-worts in flower is *Symphytum hibernicum*, which is bearing a profusion of pretty cerise-coloured blossoms; *Polemonium humile* in an adjoining bed is also a neat-flowering kind, dwarfier and smaller in every part than the ordinary kind. The exquisite little *Trifolium uniflorum*, with its magenta and white blossoms, is an interesting object on the rockery. An exception to the generally brilliant-flowered Larkspurs is to be found in *Delphinium triste*, which is now producing a profusion of sombre-tinted blossoms. *Phlox bifida* and *pilosa* are desirable kinds, which make capital companions to their dwarf congeners *P. subulata* and its varieties, all of which are now in great beauty. The best of the Irises are *I. tectorum*, a Japanese species with large purple flowers beautifully mottled with lines of a darker hue, and surmounted by a whitish crest; *I. pallida* is a lovely kind, the flowers of which are largest of all the cultivated species, and of a delicate lavender tint; *I. Cingiatii* is a dwarf species resembling *I. pumila*, but has flowers of a deeper shade, with a light-coloured beard. Amongst bulbous plants, *Pancratium illyricum* is finely in flower; its blossoms are pure white, and their large size, number, and delightful perfume render this *Pancratium* a most desirable plant, and it is perfectly hardy. *Ornithogalum orthophyllum* and *latifolium* are very similar to each other as regards flowers; they have stems nearly 3 ft. high, terminated by a pyramid of pure white blossoms, each as large as a shilling, presenting a striking appearance. The old *Camassia esculenta*, with its dark-flowered variety (*atro-vioacea*), together with the newer *C. Leichtlini*, with its tall spikes of large greenish flowers, are very attractive. The various kinds of *Calochortus* and *Cyclobothra* are now beginning to flower, and *Cyclobothra elegans* is already flowering freely. *Clintonia borealis*, which can neither lay claim to novelty nor showiness, has flowered very freely, though now almost past. *Chrysobactron Hookeri*, a very showy New Zealand plant, delights in moist, peaty beds, where annually it produces a good supply of bright yellow blossoms in long racemes.

Tottenham.—Amongst hardy flowers now in bloom at Mr. Ware's the following are of unusual interest, viz., *Fritillaria recurva*, a beautiful Californian species, with rich orange and scarlet blossoms; the Ram's-head Lady's Slipper (*Cypripedium arietinum*), a singular looking kind, the flowers of which are greenish-yellow, with a small roundish lip of a pretty rosy tint. A very dark flowered form of *Camassia esculenta*, named *atro-vioacea*, is also very attractive and decidedly superior to the type. The white flowered form of the mealy Primrose (*Primula farinosa alba*) is another pretty acquisition, the small white flowers forming an admirable contrast to those of the original. The pretty Alpine Forget-me-not (*Myosotis alpestris*) is also very fine in this establishment, its sparkling azure-blue flowers quite enlivening their surroundings. Another charming mountain gem is *Armeria setacea*, a plant which forms dense cushion-like tufts of the deepest green, studded with many heads of pretty

pink flowers. *Saxifraga Wallacei* is here, as at other places, one of the finest ornaments of the rock garden; its large pure white blossoms, which are borne in great profusion, rendering it very effective. The pretty *Primula sikkimensis* has apparently withstood the past winter unscathed, and is bearing gracefully drooping canary-yellow blossoms plentifully. A capital plant to associate with it in damp borders is *Viola pedata*, one of the prettiest Violets we know of; a peat border at Mr. Ware's is literally covered with its delicate lavender-tinted blossoms. In the same border is a mass of a large-flowered variety of *Trillium grandiflorum*, a kind much superior to the ordinary form as well as being later in flowering. *T. erythrocarpum* is a charming species, which grows about 6 in. high, and has erect flowers $1\frac{1}{2}$ in. across, pure white, with a bright carmine centre colour. The Blue Daisy (*Bellis rotundifolia cærulescens*) is finely in flower, though not of such a cerulean tint as its name would lead one to infer. The Alpine Windflower (*Anemone alpina*) is a very handsome plant, with elegantly cut foliage, forming a large rounded head, from which spring numerous pure white blossoms 2 in. across, and which have a very pretty effect.

Tooting.—In Mr. Parker's nursery the exquisite little *Campanula Allioni* is flowering in a frame. Its blossoms, which are large for the size of the plant, and borne quite erect, are of a violet-purple tint. In the same frame is *Dianthus neglectus*, quite a gem, with bright rose and white-mottled flowers, produced in abundance. A thriving batch of *Houstonia cærulea*, with star-like, mauve-tinted flowers is also very showy. *Onosma taurica* is a desirable Borage-wort for growing on dry parts of the rockwork; it has clear yellow blossoms borne in drooping clusters. The white-flowered variety of *Dielytra spectabilis* is a desirable plant, but scarcely of so robust a constitution as the original. A bed of *Primula Munroi* forms quite a pleasing feature, its pure white clusters, when seen in masses, being very pretty. Amongst the showiest of the larger plants is *Verbascum phœniceum*, now bearing tall spikes of rich purple blossoms. The sulphur-flowered variety of *Anemone alpina* is also a striking plant, its feathery foliage and large pale yellow flowers contrasting well with each other. Some rockwork covered with *Atragene austriaca* in flower is very ornamental; its large purple blossoms are scarcely inferior to those of some of the hybrid Clematises. There is also a white-flowered form which is equally desirable.

Fulham.—Bulbous plants, such as the rich purple-flowered *Camassia esculenta* and its handsome congener *C. Leichtlinii*, with its tall spikes of greenish-white blossoms, $1\frac{1}{2}$ in. across, are now very attractive at Messrs. Osborn's nursery. The various kinds of late-flowering Squills are also noteworthy, the white and the rose-coloured forms of the well-known *Scilla campanulata* being very ornamental; also the varieties of our native *S. nutans* with flowers of the same colours. The canary-yellow-flowered *Tulipa Celsiana* and the not very showy *T. viridiflora* are also now in flower in this nursery.

Effects of Local Influences on Garden Culture.—Mr. Quin will, I have no doubt, pardon me for again saying that I think the view which he takes respecting the cause of failure in the case of the plants in Mr. Tonks' greenhouse is incorrect, and not warranted by the circumstances as related. The fumes from alkali or other chemical works, such as those at Widnes, with the neighbourhood of which I am well acquainted, and where even Couch Grass for a short distance appears unable to live, are very different from those that arise from the ordinary manufactures carried on in either the Black Country or in the cotton districts, and I should have little hope of any one succeeding with plants, even under the protection afforded by a greenhouse, if near enough to the place from which the noxious gases proceed; but I do not think that at a distance of ten miles (which the Packwood plants are represented to be from the places whence Mr. Quin supposes the injury in this case comes) they would suffer perceptibly, much less be reduced to the condition in which these are said to be. In fact, I know some places where general collections of plants are successfully grown very much nearer Widnes than the distance which Mr. Quin names, and I do not think there is a place in this kingdom, or any other, where poisonous exhalations so destructive of vegetable life exist. It is impossible to grow plants without air more or less according to their kinds, and when the air is charged with impurities sufficient to injure or destroy vegetable life, the most skilful management would avail but little. The injurious effects upon plant life of poisonous gases from manufactures is a subject of great importance in this country, where works from which these arise are ever on the increase; much more is it so in the case of outdoor subjects than in that of those grown under glass; but I think in the case that has given rise to this discussion the cause must be sought for beyond atmospheric influences.—T. BAINES.

PLATE CLXXXIV.

THE MOCK ORANGES.

(PHILADELPHUS.)

THESE beautiful and usually perfectly hardy shrubs are commonly but erroneously known by growers of ornamental shrubs under the name of *Syringa*, a name which belongs to the Lilac. If an English name be preferred to that of Philadelphia, as it is by many, Mock Orange seems to be about the most appropriate, most of the representatives of the family having a perfume resembling that of Orange blossom, though of less overpowering intensity. Some of the kinds are, however, almost wholly devoid of fragrance, as, for instance, the beautiful and distinct Mexican form, which is also, alas, decidedly less hardy and robust in constitution than most of the other members of the family. The number of known varieties of these beautiful shrubs is comparatively very large, as many as fifty-five named kinds being in cultivation in the wonderfully rich collection of M. Alphonse Lavallée, at Segrez, near Paris, the accompanying plate being, I believe, drawn from specimens kindly furnished by that gentleman. Seedling hybrid varieties are also introduced and distributed from time to time by Continental growers, one of the best of which seems to be *Souvenir de Billard*, a very free blooming sort, even in a small state. The last new variety sent out this year by M. Lemoine, of Nancy, under the name of *P. multiflorus plenus*, seems, however, to be the freest blooming of them all, and well deserving its name, the small cutting-plant sent to me having three heads of bloom showing on it. There are also several other double-flowered varieties named *P. dianthiflorus*, *P. deutziflorus*, and *P. primulaeflorus*, the last said to be the most double and best of them all; but, though I have had a plant of it for three years, it has not yet bloomed, so it cannot, I think, be said to be a free flowerer. There are also two pretty varieties with ornamental foliage, one of them possessing light golden foliage, and the other having a distinct silver variegation.

W. E. G.

Children's Gardens.—Every young creature of the human race descended from Adam shows its garden origin by an instinctive love of stirring the soil in the season of vernal sunshine, and of planting in it seeds and shoots. It should be the business of those who are placed where they are responsible for the future common weal to see that all who are charged with the education of the youth of the nation shall take especial care to cultivate this tendency. Above every other temporal thing it has power to secure health, peace, and competence. A young man or woman who has learned to take interest in a garden and to grow plants well, is secure from the worst enemies of life; secure of procuring food and clothing by direct means, if indirect ones fail; secure of healthful and contenting employment for mind and body, and of innocent objects of attention and interest countless in number, and changing every day. Fortunate indeed is one whose early youth has been imbued with a liking for these pursuits and pleasures, and fortunate the society possessing such members. For they are not liable to fall into the unlawful courses which conduct the idle and the untrained into vice and crime, and make them the shame and the burden—and often the terror—of the industrious and the orderly. Our schools must find some way to teach the eager little ones the principles of plant growth. Much can be done in a city schoolroom with small pots of soil and seeds. In the country, where there are grounds fenced in, some sheltered part might easily be laid off and divided by narrow boards nailed on stakes driven down to keep them in place into a row of little lots, on each of which some easy-growing and productive plant may be set out to show what it will do when it has room, good soil, and sufficient support. On part of each lot the occupant for the season can try any of the experiments that children's whims suggest so freely. These will fail more or less, but their failure will be a lesson. The reason will appear; and the reason, too, why the Strawberry plant (grown in a pot for setting out), or the Radishes, or Tomato (trained up a stake), or Peas, or Potato, or Cucumber, or Rose have made such complete and profitable growth; these latter being protected and cultivated under the teacher's advice and care. Such instruction is given in thousands of schools in other countries. There is quite as urgent need of it here.—"New York Tribune."

***Primula cortusoides amœna* in Water.**—Is it generally known that this is a very lasting flower in water? I lately took with me to the Highlands a nosegay in which were some of these *Primulas*; all the trusses had flowers out, but some had buds. I put them into the tin on the 12th May, and into water on the 13th, and on the 30th some flowers were still in full beauty. I enclose one dried on that day; the colour has changed in drying, but it will be seen that it has kept its full shape. I saw symptoms of the severe winter in good-sized Ash trees completely barked round by rabbits as high as they could reach.—G. F. WILSON.

GARDENING FOR THE WEEK.

Stove.

THE general stock of stove plants will now be in active growth; those that bloom during winter and spring, and that are afterwards cut back and treated in a way to induce them to make mature growth preparatory to a similar production of flowers when the season again comes round, must be encouraged, so as to get them up to the requisite size before the days begin to shorten, so far as to interfere with their shoots and leaves being well matured. Cut-back plants of most kinds, as their pots get full of roots, will be much benefited by the use of manure water, but the efficiency of this very much depends upon its being applied at the right time, that is, when the greatest development of both roots and branches is going on. The stove, and likewise intermediate house, will now require more air, both as regards the amount admitted and the length of time when the ventilators are open. The much less than usual amount of sun heat which we have had all through the spring, will, except in the best houses that admit the fullest complement of light, have produced foliage of a softer and weaker character than ordinary, and which will be much disposed to flag when extra air is given; but this will do no harm if the roots be sufficiently supplied with water, and the atmosphere of the house be not allowed to get too dry during the time when air is admitted. Close both stove and intermediate house early in the afternoons, accompanied by a free use of the syringe in the case of all plants that need it; any that have flagged through the daytime will thus quickly recover, but do not keep up too much atmospheric moisture at night.

Final Potting of Winter-flowering Stove Plants.—Such winter-blooming stove subjects as are raised from cuttings annually in spring will require shifting into their blooming pots before the roots become in any way cramped. The size of the plants and their condition will determine when this operation should be carried out, and on no account ought it to be delayed longer than necessary, as it is desirable to get them fully established with a plentiful supply of roots in the pots in which they are to flower before the season gets too far advanced, for when the growth of all stock of this description is made sufficiently early in the season to admit of a short maturing process before the weather gets too cool in autumn, by giving them more air and less shade than they need when in the full height of their growth, they will always bloom more profusely than when, to attain sufficient size, it is necessary to urge on their growth until late in the season. As to the size of pots required, that must be determined by the more or less vigorous nature of each plant; such, for instance, as the free-growing *Salvias*, *Eranthemum pulchellum*, and the strong *Begonias*, will want much more root-room than the spare-rooting *Euphorbia*, *jacquiniaeflora* or *Poinsettias*, and similar plants. In all cases it is well to steer between the extremes of so confining the roots, as would be sure to result in the loss of the lower leaves, and of giving more root-space than is needed, as the latter, with anything of a coarse-growing character, has the effect of making them too large, and inducing a disposition to leaf and root extension rather than the production of bloom; and as all plants of this description can be very much assisted with liquid stimulants, when their pots get full of roots it will mostly be better not to use over-large pots, especially where the whole space available for accommodating such plants, both whilst growing and when in flower, is limited, as a larger number of moderate sized examples will be better calculated to give a succession than when a comparatively few larger specimens are prepared. Particular attention should be paid to stock of this kind through the next two months, in order to keep it near enough the glass of the pits and frames occupied, to prevent the shoots from becoming weak and long-jointed, for when this takes place, no amount of after care will ever induce the plants to flower so profusely as they ought. In order to still further effect this, whatever shading material it is found necessary to use should not be thicker than is requisite to shield the plants from injury; ordinary bast mats, which from want of a more suitable material are often made shift with, exclude too much light; the shading thus applied should never be on the glass longer than needful. Fixed shading, in the shape of canvas tacked on the glass, or any of the various compositions used for smearing it with a view to save labour, are all more or less objectionable, for the simple reason, that for the few hours in the middle of the day during the brightest weather that it is necessary to temper the effects of the sun's rays, there is a much longer period during the morning and evening, when they minimise the light which the plants want in the fullest amount available.

Nepenthes.—The cultivation of these is now so much better understood than it was at one time, that no one need hesitate growing them who is in possession of a house, large or small, wherein is kept

up a temperature sufficient for the warmer section of stove plants; they may be grown as climbers either planted out or, still better, in pots, as more control can be kept over their roots, with a view of preserving them in a good healthy condition. They can be run round a pillar or up a rafter, but in the case of most of the best and finest species, after the growths have attained a few feet in height, they assume a condition known amongst plant cultivators as "run-out," that is, the pitchers assume a different shape, and generally become destitute of some of the parts which they possess before the shoots extend so far, and in this state are very much less interesting than they otherwise would be. For this reason they display their full development, and are usually most attractive when their growth is confined to pots of comparatively small size, so as to admit of the plants being suspended from the roof of the house in which they are grown in a way so as to keep their heads near the glass. They must now be regularly shaded, as the sun at this season is much too powerful to be allowed to shine directly upon them; but the shading used should be thicker or lighter, according to the position in which they are placed; if in houses that stand with one side fully facing the sun at midday they will need it thicker than if in structures standing in the opposite direction. I allude particularly to this, as if the material employed excludes too much light, the plants are drawn up weakly, and the pitchers are devoid of the high colouring that so much enhances their beauty. They will now require a good soaking of water every day at the roots. I have found it best to give them this in the mornings, as when the soil has been recently moistened, it enables the plants to better withstand the drying influences of the midday sun, and air which it is necessary to admit to the house; at the time of closing, let them be freely syringed with tepid water, an operation to which it is necessary to attend regularly, otherwise thrips are very liable to establish themselves on the under sides of the leaves, where from their drooping position, unless care is taken that the water reaches them, they are enabled to remain secure; thus they very soon increase to an extent that proves permanently injurious to the leaves. There are few plants, if any, with which I am acquainted that need so little root room as *Nepenthes*; but when any have become evidently too large for the pots which they occupy, they should at once be moved into others 1 in. or 2 in. larger, according to the condition of the roots and the size of the specimens. In this operation neither the old soil nor even the crocks should be disturbed further than removing such as can be got away without interfering with the roots which are extremely brittle, and more impatient of injury than those of any other plants with which I have met. Let the material used, which should be similar to that recommended for the general winter potting before growth commenced, consist almost exclusively of vegetable fibre, intermixed with a very small portion of earthy matter; as the shoots extend each will require a stick to support it, but when inserting these in the pots be careful not to disturb the roots more than may be unavoidable.

Cephalotus follicularis.—This interesting little plant is sometimes assigned to the stove, and sometimes to the greenhouse department; the fact is, it may be cultivated in either, but the treatment which it should receive in these different temperatures requires to be considerably varied; as a matter of course, in the stove or intermediate house it grows much quicker than in the greenhouse; but, unless subjected to more light by being placed near the glass, the luxuriant growth made for a time will be so far deceptive that the plants will become exhausted, and ultimately dwindle away altogether. The best position I have found for them when grown with more or less heat is where there happens to be a shelf just beneath the lower end of the roof lights, where the bell-glasses necessary to cover the plants will be all but touching the roof; grown in heat in this way, the glasses should be tilted continuously during the growing season, more or less in accordance with the amount of air that is admitted to the house. This *Cephalotus* being really a swamp subject, should never be allowed to get dry at the root; and if the pots are well drained, and the material in which the plants are grown be of an open fibrous nature, there is little to fear from over-watering. It may be propagated freely by division of the small crowns, or side growths, usually produced from the main stem, which when they have got three or four leaves each generally form roots; if they are placed separately in the smallest pots, and filled with vegetable fibre from the best *Orchid* peat, added to an equal portion of chopped sphagnum, a little sand, and a few bits of charcoal or crocks broken fine—material in which they all grow freely. In the case of either fine or small examples of this plant, the pots in which they are grown should be placed in another pot sufficiently large to accommodate them, and filled with sphagnum, to admit of the covering bell-glasses standing within the rim of the pot. Where there is stock enough, a correspondingly more effective specimen may be made by plunging a number of pots containing individual plants in a large pan, or pot, covering the whole with a bell-glass.

Dionæa muscipula.—This plant, which is so suitable for associating with the *Cephalotus*, like it can either be grown in a cool house or in an intermediate temperature; but I have found it to be more influenced by light than almost any other plant. When grown in too dark a position the leaves produced become much attenuated, are less enduring and with correspondingly fewer roots, and not so vigorous in condition collectively; but, if too much elevated, so as to be over-near the roof, unless regularly shaded when the sun is on the glass, it generally dies altogether. I should recommend those who attempt its cultivation, or who have tried and failed, to place it in different positions in the house; when rightly placed, the trap-like appendages at the ends of the leaves will assume a beautiful reddish-bronzy colour, which may be taken as certain evidence that the situation suits it, and that it will not only continue to thrive, but increase so as in a few years to enable the cultivator to have considerable stock at command. Where it is at all strong, and throws up flower-stems through the spring or about the present time, as soon as these are apparent they should be at once removed, as the interest attached to them is not sufficient to compensate for the weakening tendency which they have on the plant. Keep the plants daily supplied with water, and from time to time see that they are free from green-fly, from the presence of which they suffer more than most plants. They sometimes succeed admirably in a house where there is a good deal of air given, with a bell-glass over them, tilted so as to admit air. They will grow in material such as that recommended for the *Cephalotus*.

Droseras.—There are now several forms of these singular plants quite distinct in habit from the ordinary British species; they grow to a height of 10 in. or 12 in., and have elegant subdivided leaves, profusely armed with glands, similar to those of the usual bog species. They thrive well grown in small pots in soil the same as that named above, the general treatment being also similar. They should have water in sufficient quantity to keep the soil continually wet, and a light position, in which the glands assume the beautiful red tint natural to them, and which so much enhances their appearance. As a rule, they succeed better a little more confined than the *Cephalotus*, that is, with the bell-glasses placed over them not so much tilted. —T. BAINES.

Flower Garden.

Auriculas.—It seems from remarks in last week's GARDEN that it is quite time that repotting was finished. I meant to say (p. 457) that ours were not yet potted, owing to want of time, although the largest proportion are finished. I have noticed in repotting that those potted in April and May last year have well filled the pots with roots, which are exceedingly healthy, and that those potted later, in July and August, are not nearly so satisfactory as regards the state of the compost or the health of the roots. It is evident that the Auricula does not make the largest quantity of roots between the last week in July and the end of the blooming time. Those who sowed seeds in July or August last year would do well to pay considerable attention to the plants at present, in order to get as much growth as possible, so that that they may be strong enough to flower next season; for if they do not flower, there will be the trouble of growing them for another year. See that they are kept clear of aphids by brushing them off or fumigating. We have occasionally dusted the plants with fine dry Tobacco powder, which will also destroy aphides to a limited extent. There has been no need to warn growers about injury from too much sunshine; but, should very hot, sunny weather set in after so much dull, cool weather, it will be desirable to shade when the sun shines directly upon the plants.

Carnations and Picotees.—In town gardens where green food is scarce, sparrows attack the flower-buds of these just as they are formed. This warning may be necessary, as the mischief is usually done early in the morning, even before five o'clock. The buds where injured look as if they were bruised by the fingers. White threads stretched over the plants sometimes keep them off, but a net placed over the beds is most effectual. Some of the most forward of our plants now require disbudding; it is desirable to remove the centre bud, when three side ones will push out strongly and flower about a week later. Those intending to exhibit will do well to take note whether they are likely to be late or early for a certain date, and disbud accordingly. The stems grow very rapidly, and it is necessary to frequently look over the plants, in order to furnish them with fresh ties, and to see that the stem is not injured by the old ones.

Dahlias.—These have not yet been planted out, but we hope to do so at once; the plants are quite ready, and no danger need be apprehended now from frosts. They have been kept longer in pots than usual, but we have not allowed the roots to become matted, which should always, if possible, be avoided. Our plan is to drive the centre permanent stick into the ground firmly, and then dig out

about two spadefuls of soil in front of it. We then fill this opening with good loam, enriched with about one-third part of rotten cow or stable manure, or what is perhaps preferable, both sorts mixed. In this the plants are put out, pressing the soil firmly round their roots with the hands. The their tops to the sticks at once, in order to preserve them from injury. The present moist state of the ground and atmosphere is very favourable for slugs; therefore, see that they do not eat the leaves at night.

Pinks.—The earliest of these should now be in flower, but there is no sign of bloom at present; the plants are, however, healthy and the flower-stems strong, giving promise of a good display, even if late. The stems have just been tied to neat sticks of dried Osiers; the surface soil has also been stirred up, and the beds cleared of weeds.

Pansies.—These are now making a healthy growth, and the flowers are large and of fine quality, though the rains occasionally injure them. The plants delight in a moist atmosphere and plenty of moisture at the roots. Peg the stems out if the plants have not covered the beds.

Phloxes, Pentstemons, and Pyrethrums.—These are placed together, because the work required to be performed is very similar in each case. Old-established plants are apt to become overcrowded with flower-stems; these must, therefore, be thinned out before they injure each other. The stems must be tied to their sticks as they advance in growth.

Aquilegias.—These are now exceedingly beautiful. The light blues, *A. corulea* and *A. corulea hybrida*, are charmingly brought out when the plants are grown in pots and protected from rain under glass; they form at present quite a feature in our greenhouse. When in flower they require considerable supplies of weak manure-water; the leaves ought to be free from red spider and green fly before the flowers open.

Polyanthuses.—Old plants of these put out in the open ground from pots seem to revel in the dripping weather and moist atmosphere which we are now experiencing. See that the surface of the beds are lightly stirred and weeds removed. Seedlings come into flower much more rapidly than those of Auriculas. Seeds of them sown in March or April make strong-flowering plants by the end of the year. I sowed in pots about the first week in April; the seedlings were pricked out into boxes, and when the leaves meet together the plants will be put out about 6 in. apart, when they will flower the following spring. —J. DOUGLAS.

Indoor Fruit Department.

Vines.—Continue to attend to timely thinning out of both bunches and berries, stopping lateral growths, watering, &c. Growth now goes on so rapidly that a single day's procrastination in the execution of any of these operations cannot take place without injurious consequences; an effort should, therefore, be made to perform every operation at the right time. It is curious to note how, under entirely opposite conditions, the same end is sometimes attained—a case in point being our large house of Lady Downes; this, for the past two seasons, did not set its fruit so well as was desired, some few of the best bunches having to be cut off, and yet every pains was taken to disperse the pollen, and the weather was all that could be desired, and now this season, though there has not been a single hour's sunshine during the time when they were in flower, and no attempt at artificial fertilisation made, other than a shake of the trellis, every bunch is so thickly set that it is with difficulty they can be thinned. Such a circumstance is calculated to set one thinking, and the only solution I can at present give is, that the Grapes were cut and bottled a month earlier than usual, hence the Vines have had a longer rest, and are consequently better able to stand a strain at this early stage of growth than they otherwise would have been; should my surmise be confirmed by another season's experience, I shall look upon early harvesting of the ripe fruit as an important item in the cultivation of this best of all late Grapes, for surely it deserves this designation, seeing that we have bunches now (June 7) with berries as plump and carrying as fine a bloom as when they were cut at Christmas, and in flavour at least equal to newly-ripened Hamburgs.

Peaches and Nectarines.—As these will not keep long after being fully ripe, in order to lengthen out the succession let the houses be freely ventilated night and day, in order that full maturity may be developed as gradually as possible; the flavour will also be better in consequence. As soon as all the fruit is gathered the trees may receive the same treatment as they did in the earlier stages of growth, and the shoots intended for next year's fruiting should have full exposure to sunshine by the removal of all others that are not required for furnishing the tree. The border, too, must be as well attended to as it was before the fruit was gathered; indeed, at no time should it be allowed to get dry, or even dryish, as is sometimes

recommended, under the delusion that it aids the ripening of the wood. Thin the fruit in succession in late houses, and regularly stop all lateral growths, but particularly when the fruit is in its last stage as regards swelling; well ply the syringe till it begins to change colour, and this will keep down red spider. For green fly nothing is so effectual as fumigation, and for mildew plenty of root moisture and sulphur dusted over the affected parts. Fire-heat ought not now to be necessary, but growth should be pushed on by closing the ventilators early, and so making the most of sun-heat.

Pines.—Usually at this season there is a redundancy of ripe fruits which it is desirable to keep in good condition for as long a time as possible, and one of the best ways of retarding them is just before they are fully ripe to transfer the plants to a cool, airy house, and shade them from sunshine. A well ventilated fruit-room, if not too damp, is an excellent place for them. Where room cannot be had for the plants, if the fruit be cut and suspended in a cool, airy position, it will keep a considerable time in that way, but the former plan is preferable. If there be any fruits required by a certain day, and it is thought doubtful as to their being ripe at the time, a push can be made by keeping a closer and moister atmosphere than is generally desirable when the fruit is ripening, but it must be remembered that such extra forcing will to some extent be a loss as regards high finish and flavour, and therefore such extra forcing should never be put in practice, except under the most unexceptionable circumstances. All varieties of Pines attain the highest perfection of finish and flavour if, as soon as they begin to colour, they have what may be termed greenhouse treatment, and are allowed from this stage to ripen as slowly as possible. It is usual to withhold water when this stage has been reached, but having broken through this rule by keeping them moderately moist to the very last, the results are so largely in its favour that now we always water moderately. The autumn and winter fruiting varieties now showing fruit should have the most liberal treatment. A bottom heat, ranging from 85° to 90°, must be maintained, and the plants must be well supplied with water; they should be examined twice a week with reference to this matter, and guano water or other liquid manure should be used at every alternate watering. Until they are in flower the air-moisture cannot well be too excessive, but at that time a drier but not arid state is necessary till they are out of flower, when moisture may be again increased. Seeing that there has as yet been only a few fitful gleams of sunshine, and the tissues of the plants are too tender to withstand bright weather, particular care will still be requisite, more particularly in the case of smooth Cayennes and recently potted plants. The strongest suckers from the earliest ripened Queens may now be potted, and if grown on freely from the first, they will make the finest summer and early autumn fruiters next year.

Strawberries.—From the experience of the present season, it seems to me that these will attain perfection without sunshine, for one hears on all sides how good they have been, not only to look at, but to eat. I interpret the matter thus: the weather has been continuously dull and cloudy, so comparatively little water has been required, increased fire-heat has been neutralised by increased atmospheric moisture, and so a moist heat has been engendered (the entirely opposite of that afforded by sun-heat), and this, combined by free ventilation, which all know Strawberries must have, has ended in the production of as finely-flavoured fruit as could have been expected in the most favourable season. That old and long-continued favourite forcing kind, Keen's Seedling, cannot be excelled in quality, but, having gained some notoriety for its knack of non-setting and blindness, its popularity is on the wane. Sir Charles Napier, however, well ripened, is too acid for many palates, and so also is Sir Joseph Paxton, whilst British Queen is too shy a bearer, at least under ordinary conditions, so that the varieties President and Vicomtesse Héricart de Thury, with me at all events, must have first places. These are still producing as fine fruit as anyone could desire, and all the cultural aids now requisite are a full supply of clear manure-water and the removal of redundant fruit.

Figs.—As soon as the first crop has been gathered, thoroughly cleanse the trees, walls, and glass by means of a free use of the garden engine, and, if necessary, apply a fresh top-dressing to the border; in any case there should be a renewal of the mulching, and the inside borders should be well soaked with warm water. All surplus second-crop fruit should be at once removed, and the trees should be syringed early in the morning and at shutting-up time. Very little fire-heat will now be necessary, all the forcing requisite being obtainable by early closing on sunny days. The same remarks are equally applicable to trees growing in pots, except that those bearing ripe or ripening fruit must be kept drier both at root and top.

Melons.—As we never attempt the growth of these in any other way than in houses heated by hot water, the notes under this head are only applicable to the growth of Melons treated in that manner.

The earliest fruit will now be cut, and if the plants have retained their foliage good to the last, they may again be left to produce another crop. In order to encourage this, let the bed be thoroughly saturated with warm water, and immediately mulched with 3 in. or 4 in. of droppings. Shorten back the laterals to within two or three joints of the main stem. Syringe regularly, and otherwise treat as recommended in the case of young plants, and a crop of fruit will be had much earlier than from young plants. Of course if the plants have been damaged by spider or otherwise it is best to discard them; cleanse the house, renew the border, and replant with young plants. Support swelling fruit with pieces of netting before there is any danger of their weight breaking down the Vines, and take every pains to keep the foliage clean to the last, tying any aside that overshadow or prevents the sun from reaching the fruit. Succession plants should be examined for the purpose of fertilisation when the maximum daily temperature has been reached, and if three, or at most four, on each plant can be fertilised at the same time, it will conduce to more even and certain swelling off. Stop the laterals to reasonable extent only; so long as there is room without overcrowding, the more foliage there is the better. In case the old plants get injured, and are not equal to the production of a second crop, another sowing may now be made.

Kitchen Garden.

If, as is generally believed, a long and severe winter kills slugs, how is it that they are now as numerous as ever? At this place they certainly are, if anything, more numerous, or at least more troublesome, than in any previous season; and to save such seedlings as Beet, Cauliflower, and Lettuce, we have had to apply repeated doses of lime and soot, and also to trap them with Cabbage and Lettuce leaves and small patches of bran. This latter bait must have the palm for effectiveness. It appears to be a dainty morsel to them, for so long as a bit remains nothing else is touched. Peas are, I suppose owing to the wet, growing abnormally tall; we have, therefore, topped them, hoping to prevent the injury that might befall them through their getting too tall for the stakes. Doubtless in good ground all kinds will this year grow taller than usual, and topping may be done with advantage. Late kinds may still be sown, except in cold, bleak localities, and there early sorts should be put in. William the First is about the best of all the early kinds, being within a day or two as early as Kingdealer, and equal in quality to Champion of England. French Beans have grown very badly this season, and those who took the precaution to sow in boxes, with a view of transplanting, have acted wisely. Now, however, they must germinate out-of-doors, and should be sown in quantity for autumn use—2 ft. apart from row to row, and 9 in. asunder in the row. The taller-growing kinds, such as Canadian Wonder, ought to be supported with Birch twigs; double produce may then be had, for this variety grows so tall, and bears so profusely, that the haulm is weighted down, and much of the produce gets spoiled if the plants are not thus supported. Lose no time in finishing the thinning out of seedlings of Parsnips, Carrots, Onions, and Beet; the last of these transplants fairly well, but care must be taken to keep the points from doubling up in the process, or forked roots may be the result. Fill up every spare bit of ground with winter greens, Coleworts, and Cauliflowers. Prick out Broccoli ere they get spindly by being left too long in the seed-bed. A few of an early kind, such as Veitch's Self-protecting or Snow's, should be permanently planted to succeed the autumn Cauliflower. Celery, too, must now be got out. We always plant in double lines, in trenches 30 in. wide and 9 in. plant from plant, using the best manure at command. If the weather be dry when first planted, a good watering is given, and once weekly in dry weather to keep the plants growing; for, if once drought checks growth, they are sure to run to seed. Free, unchecked growth never fails to produce solidity, which enables Celery to withstand any reasonable amount of frost without protection. Sow Lettuces and Endive thinly where they are to stand, and thin out those previously sown to 9 in. or 12 in. apart, and prevent slugs from attacking them by the means just named. Sow Radishes, Mustard, and Cress in any spare corner every week or ten days. If Herb seedlings and the Herbery generally have not yet received the attention recommended (p. 395), it should be given now, or several kinds may be wanting when required by-and-by. We have generally made it a rule to discontinue cutting Asparagus as soon as Peas are plentiful; but, as a full supply of these will not be had this year till quite the end of the month, or perhaps July, it is evident that that rule cannot be adhered to this season, more especially as the demands on it have already been greater than usual, through the winter destroying other vegetables. All who can afford it will, therefore, act wisely to discontinue cutting forthwith. Scrupulously guard the stems of any that has been recently planted from injury. The plan of sowing Lettuces, Radishes, &c., between the rows cannot be too severely condemned.—W. V.

THE INDOOR GARDEN.

CULTURE AND PROPAGATION OF SOFT-WOODED HEATHS.

CAPE Heath is rarely found in good condition in small gardens, many not even attempting their culture from the mistaken impression that it presents difficulties which a small grower with but limited glass accommodation cannot surmount. So far is this from being the case, that any one who possesses a greenhouse and a cold frame, or even only the latter convenience, may grow these interesting plants, as well as those who enjoy the convenience of an extensive range of glass. The free-growing varieties of the Cape Heath should indeed be regarded as especially suitable for amateurs, inasmuch as they may be grown during a portion of the summer in the full sun, not needing the slightest protection from its rays, and in winter they will be content with the accommodation of an ordinary frame, and will bear, without manifesting any signs of distress, a considerable amount of frost. I have known one of the largest collections of Heaths in this country to be repeatedly frozen, the soil in the pots being so hard that a pointed stick could not be thrust in it. I would not, of course, advise this treatment; I merely mention the circumstance as tending to prove that Ericas are not of such a tender nature as many suppose them to be. Neither does their general culture present any formidable difficulties, as any one who can grow an Azalea may succeed in cultivating any of the soft-wooded section of Cape Heaths. Many causes of failure in the culture of this tribe of plants may be attributed to undue confinement, both in summer and winter. Abundance of light and air is indispensable to their well-being. I need scarcely urge the decorative value of the Heath tribe, most plant lovers being well aware that it exhibits considerable variety of form and colour, and that many varieties have the merit of flowering at a season when bloom generally is scarce.

Soil and Potting.

With respect to soil, the beginner can scarcely make any mistake, as the only suitable compost is fibrous peat. Every care should be taken to secure some of the very best quality, as although Heaths will live and even grow a little in poor peat, they never attain a vigorous development, but linger on in a miserable way, utterly failing to develop the floriferous tendency which characterises this family of plants. Sour peat produces even more disastrous results; the rootlets, which are of a minute, hair-like description, absolutely refuse to mingle with it, and a healthy plant shifted into peat of this description will generally turn yellow, make scarcely any growth, and when turned out the old ball will come away from the new soil in much the same state as when potted. I have felt it necessary to dwell somewhat at length upon this matter, as so many failures occur from this cause alone, and I know from experience that few families of plants are so particular with respect to soil as are the Cape Heaths. Give them a good, generous, suitable compost, and any one may grow them to perfection; pot them, on the contrary, in soil which does not fulfil these conditions, and failure and disappointment will assuredly follow. In preparing the soil for use many of the best growers prefer breaking it up by hammer to chopping it; it should be broken into pieces about the size of a nut, and about one-sixth of silver sand should be added to and intimately mixed with it. If very dry it should be moistened before being used, which is best effected in the following manner: Spread a thin layer of soil upon the potting bench and sprinkle it; follow up with another layer of soil, which must also be moistened, and continue this until the entire heap of compost is worked through. Allow it to lie until the following day, when it will be found that every particle of mould is moistened through, thus bringing it to just the right state of moisture for potting. When used in a dry state, heavy waterings are rendered indispensable, in order to thoroughly moisten it, and it often occurs that a considerable amount of injury is thus inflicted upon the young fibre. If the base of the plant to be shifted is in a moist condition, and the compost employed is also moist, immediate waterings are obviated, and the roots will have commenced to penetrate the fleshy soil before much water is needed. Good free drainage is of great importance. For 4-in. and 6-in. pots a piece of crock large enough to nearly cover the bottom of the pot should be employed. Upon this place a layer of fine crocks from which the dust has been sifted; finish off with some of the most fibrous portions of the compost. When about to repot make sure that the base of each plant is thoroughly moist. The best way is to look through them the night before potting, well watering those that appear at all dry. Do not attempt to remove any of the old soil, as such a practice is sure to entail the destruction of many of the best feeders, and be careful in extracting the old drainage not to bruise or break off the roots, which are almost always to be found amongst it. The fresh soil should be pressed in firmly,

and the surface should also be made firm, which has the effect of causing the water to percolate gradually through and thoroughly soak every particle of soil in the pot. A small lath is often employed for ramming the soil down; but I should warn the inexperienced against making a too free use of this implement. I have known the soil to be pressed in so tightly as to render it almost impenetrable to the roots. In this matter there is a happy medium, which if attained will ensure success.

General Treatment and Varieties.

We will now suppose that the plants have been potted in the manner recommended, and have been placed in a cold frame upon a well-ashed bottom. They will need a little air on fine days, and may be slightly syringed in the afternoon, watering when needful, but not heavily. As they begin to grow both air and water will have to be more liberally supplied, gradually increasing the ventilation until the sashes can be entirely removed both day and night. Heaths enjoy a maximum of sun and air, and they do not flower freely unless they get it. Market growers and nurserymen generally arrange their plants during the summer months in long beds, allowing plenty of space between each plant, and the success which attends this treatment fully testifies to its value. A sturdy, close habit is thereby induced, the foliage takes on a healthy green colour, and the flowers are produced in profusion. In hot weather copious supplies of water must be given. The most strict attention in this respect is needful, as if once a plant droops from want of moisture, it never appears to grow with any degree of vigour afterwards. In the hot days of July and August, when the pots have become full of roots and a large amount of foliage is developed, evaporation in the full sun goes on so rapidly, that some of the plants are almost sure to suffer unless they are looked through twice during the day. The rule should be to water them that need it in the morning, somewhere before midday, and then towards evening give them all a thorough soaking. In very parching weather a good moistening overhead will also prove beneficial. Should the season prove damp, mildew will often make its appearance, and if unchecked will completely paralyse the energies of the plants. It is, however, easily destroyed if taken in time in the following manner: Enclose flour of sulphur in a fine muslin bag, invert the plants, and dust the whole of the under side of the foliage. Wherever there is mildew the sulphur will adhere, and will, in about a fortnight, quite dry it up. By the end of September the plants should be placed in their winter quarters. If there is a scarcity of room in the glasshouses they may be successfully wintered in a cold frame. In some large trade establishments many thousands are thus wintered, and although in a severe season the frost may penetrate to and freeze them a little, they do not appear to be the worse for it. I would of the two prefer to have them rooted to placing them in a house where they would not be sure to enjoy the amount of air which is so necessary to them. The treatment which, in this respect, the ordinary run of bedding plants receive during the winter will also suit the Heath family. Plenty of air without cold draughts should be the rule. Plants in 4-in. and 6-in. pots are very suitable for room decoration, but those who wish to preserve them in health and grow them in for another year should not keep them more than a week at a time in the dwelling, neither should they be placed in an apartment where a fire is constantly maintained or gas burnt. They may be employed to decorate those apartments which are kept comparatively cool and airy, and if taken out and well sprinkled, and allowed to remain for a few days to recruit their strength, they will not suffer, and may be again employed in the same manner. As soon as each plant is done blooming, let it be cut down below the flower-spike, and be placed in a cold frame in readiness for shifting. Although the generality of soft-wooded Heaths are found to be most useful for general decorative purposes when grown in small pots, yet larger specimens will be found very effective. In large conservatories, for instance, well-grown plants in 8-in. and 10-in. pots are useful, and, owing to the pleasing neutral tints which many of them display, they associate well with and help to subdue the glare which is often rather too pronounced when a quantity of very bright-flowering plants are brought together. The following are a few of the best varieties, all or any one of which are suitable for beginners, and afford a succession of bloom during the winter and spring months: *hyemalis* and *gracilis* autumnalis, the two best winter-flowering kinds; *gracilis* vernalis, similar to the last-mentioned kind, but flowering in early spring; *Willmoreana*, a strong grower and very effective; *Sindryana*; *caffra* nana, a dwarf-habited, free, white-flowered kind, of an enduring nature; *propendens* tubiflora, a very pretty variety; *candidissima*, pure white; *colorans*, and *Bergiana*, the latter an extremely fine-flowering pink-coloured kind, admirably adapted for growing into a large specimen; *persoluta* alba and *rubra*, easily grown kinds, very useful for cutting. The above are some of the most useful varieties. There are many more good kinds, but those enumerated will suffice to keep up a succession of bloom during the duldest part of the year.

Propagation.

In trade establishments where the culture of Heaths is made a speciality, the method of propagating is as follows: Early in the year healthy plants of the kinds it is desired to propagate are introduced into gentle warmth; in due time they produce a quantity of soft shoots. These are taken off, and the lower portion of each cutting is trimmed up with a small pair of scissors, the greatest precaution being taken to preserve them from the drying influence of the air. Six-inch pots, which have been filled to about one-third of their depth with drainage, are filled up to within 2 in. of the rim with fine fibrous peat, which is surfaced with silver sand. The sand must come up to the rim of the pot, and should be shaken down firmly, so that when moistened it does not sink any lower. When filled, place the pot in a tub of water, so that the whole body of soil may become thoroughly moistened, when they should be allowed to stand and drain several hours before using them. Then take a

fest, a little air should be given for a few hours each day, tilting the bell-glass slightly on one side, and increasing the ventilation as growth progresses until the glasses may be altogether removed. The hardening off must, however, be very gradually conducted; undue haste will cause a very serious check, and will often entail the loss of the little plants. When fairly hardened off they may be potted in 2½-in. pots and kept in a warm house until well established, when they may be removed to a cold frame. During that season and the following they will need to be kept pinched back, so as to induce a bushy dwarf habit, and promote the formation of a mass of feathery foliage near the pot. Unless a Heath is well furnished with healthy foliage down to the soil, it can scarcely be said to possess any true decorative value. On the Continent a different method of propagating is practised from that above described. There cuttings are inserted in the month of August, and inserted much in the same manner as in this country, but they are placed in a cold

Chysis Chelsoni; a new Hybrid Orchid, between *C. bracteescens* and *C. aurea*.

bell-glass and imprint its outline upon the sand, thus exactly indicating the area to be filled with cuttings. If straight lines are then drawn from one side of the circle to the other, the cuttings may be neatly and expeditiously inserted. As each pot is finished it is covered with a bell-glass, and a gentle watering given over the glass. It is, indeed, only in this manner that future moistenings can be administered, as sprinkling in the ordinary way generates mould, which is so deadly in its operation, that two or three days only suffice to sweep off a potful of cuttings. The pots should be plunged up to the rim in a tan bed, and strict attention must be paid to shading them, as half-an-hour's exposure would suffice to destroy the most promising of cuttings. Every morning the glasses should be taken off and the insides wiped quite dry, at the same time giving a glance at the state of the cuttings. Should there be any signs of damping, remove at once the decayed portion before it has time to infect the remainder. As soon as any signs of growth are mani-

frame until housing time, when they are transferred to a warm house. During the winter they take root, and are potted off in the spring. Both systems have their advantages; by the former a great number of cuttings are obtainable from a single plant, as, by keeping it in a warm house, fresh shoots are continually forming to replace those taken off; therefore, so many plants are not required to furnish cuttings, and a stock may be quickly worked up. J. C. B.

Chysis Chelsoni.—The annexed woodcut represents a fine hybrid raised at Messrs. Veitch & Sons' establishment at Chelsea, and, on account of its distinct character, a decided acquisition to the small genus to which it belongs. It is the result of a cross between *C. bracteescens* and *C. aurea*, and partakes of the character of both parents. The colour of the flowers is nankeen yellow, with a large rosy blotch on the tips of the sepals; the lip, which is bright yellow,

is pencilled and spotted with purplish-red. As evidence of its superior merit it has received first-class certificates from the Royal Horticultural and Royal Botanic Societies.

SHADING CAMELLIAS.

The ability of Camellias to stand exposure to the sun depends upon circumstances, and, meanwhile, I would recommend "Enquirer" (p. 466) to be cautious as regards exposing his plants that have been grown in a glasshouse and partially shaded, though he may, without hesitation, place them out-of-doors behind a high north wall or hedge where they will be protected from the fiercest rays of the sun. The plants should, however, have completed their growth before being put out and showing their rudimentary flower-buds. July is usually soon enough to place Camellias out-of-doors, and they may remain out two or three months. The practice is, however, only advisable when the Camellia house is wanted for other purposes during summer, for there can be no doubt of the advantages of keeping them indoors all the year round when practicable. As to exposing Camellias to the "full blaze of the sun" under glass, that is a point on which "Cambrian" differs from most other cultivators. My own experience is that in our fitful climate it is not safe to dispense with a slight shading after April. After a period of dull weather particularly I find that the foliage is almost sure to suffer from bright sunshine, notwithstanding abundant ventilation day and night, and the vigorous health of the plants. The scorching, or whatever it may be called, is due sometimes, I fear, to lenses in the glass, as I have not unfrequently seen a bush struck right across in a straight line, and the same thing happen at the same place at different times, but as a rule blighting occurs indiscriminately when the plants are exposed to bright sunshine through a glass roof; and this appears to be the experience of most cultivators. Nurserymen and owners of some of the finest collections of Camellias round London and elsewhere, shade their houses, and also recommend the practice. One of the finest houses of plants with which I am acquainted, whether as regards size and health, or the abundance and quality of the blooms which they produce, are permanently shaded by scrim canvas throughout the summer. Another private collection which includes some of the oldest Camellias in England, all in robust health, has been shaded every summer for many years back by having the roof painted green. Many of the plants are trees in size, and have never been out of the house. Upon the whole, I think the best advice that could be given on the subject is to shade slightly from bright sunshine. It is certain, at least, that shading will do no harm, and it may very probably prevent serious injury. That the Camellia when grown out-of-doors will stand the most intense sunlight there can, however, be no doubt. Plants growing in shrubberies in the full blaze of the sun are common enough, and for my part I never saw one injured. An old bush here has been growing against a south wall, where it is exposed to the sun all day, and yet it is as green and healthy as can be. In the dry summer of 1863, and in more recent years, when the outdoor thermometer in the shade registered 85° and 90°, this bush did not suffer in any way, but retained its foliage fresh and green; yet it must often, and for long periods at a time, have been exposed to a sun temperature of 130° or more against a brick wall. The fact, however, that Camellias will endure such exposure out-of-doors does not affect the question of shading them when grown under glass. There are not a few subjects besides the Camellia that will stand strong sunshine and a high temperature in the open air that would become blistered or scorched under a glass roof.—J. S. W.

—The query put by "Enquirer" as to the most suitable position in which to place Camellias in the open air is one that will doubtless be answered diversely, just as the Camellias under notice have been grown in shade or sunshine. As a rule, in house culture there can be little doubt that shading more or less is employed, especially if the plants be near the glass. If Vines or climbers partly cover the roof, then generally more than enough shading is provided. The chief danger to the foliage when exposed to the full glare of the sun under glass is blister, but this is no doubt produced by excessive concentration of the sun's rays upon a given spot through some defect in the glass. Therefore, it is not certain that the same mischief would follow in the case of plants in the open air, as there the sun's rays are equally distributed; the heat is never so great, and the sun does not possess scorching power until the foliage is hard and the wood partly ripened. Camellias planted in the open ground are fully exposed to the sun with impunity at all seasons, but the foliage does not suffer. From this fact it is but fair to infer that the more the foliage is exposed to light and air under glass the less danger is there of its becoming scorched. Probably the chief danger to Camellias in pots likely to arise from full exposure to the sun would be the extreme hardening and drying of the balls of earth

that might follow. This could be obviated by the use of some plunging material, but I think in placing them somewhat in the shade in the open air growers will prove as thoughtful of the roots as of the foliage.—A. D.

—In old dark houses, the roofs of which are constructed of almost half wood, with small panes of glass and their innumerable dirt-holding laps, Camellias can doubtless be grown without shading and without their leaves being burnt or discoloured, but not in houses of modern construction, built, as they ought to be, in a way capable of affording the most light to the plants they contain, which may be Camellias one season and plants of a wholly different character another—not but that Camellias are very much better for being grown in a structure that affords plenty of light, but the admission of light and allowing the leaves to be injured by full exposure to the sun's rays are very different. And in how many houses of fair construction can Camellias be put to make their growth without their leaves being absolutely burnt, unless shading of some sort be applied? The position of a house has a good deal to do with the sun affecting the plants within it. I have had to deal with Camellias in a good many houses, varied in character and standing in various positions, lean-to's and hip-roofs facing south, as well as span-roofed with the ends east and west, and in the opposite way, and also a good many of my own planning, in which I have used all care in selecting the best British glass, but not even in a roomy span-roofed structure, with its ends north and south—in which direction, as is obvious, the sun's rays reach the plants in an oblique direction, still further protected at mid-day, when most powerful, by the bars and also rafters, where the latter were employed—have I ever yet been able to dispense with shade of some sort without the leaves suffering to some extent; neither have I ever seen these plants with others in a good modern-built house do without shade at the time when they were making their growth in the spring and summer months. As to turning them out-of-doors fully exposed to the sun, much depends upon the time when they are so turned out; if towards the end of summer, little injury may follow, and their susceptibility to be affected by the sun will be influenced by the way in which they have been treated whilst their growth was being made, and also by their being gradually brought from a shady position into a sunny one; but I have frequently seen those who have thus exposed their plants regret it; many of the leaves, although not burnt as when under glass, became reddish-grey, a colour which they often assume when so treated, and which is not only unsightly, but does serious mischief by shortening their duration. May I therefore ask what is gained by attempting to either grow Camellias unshaded, or by exposing them to the sun out-of-doors after their growth is completed, especially the latter? For my own part, in the case of such as are in pots or tubs, I much prefer, when their growth is finished, putting them in a lean-to north house where available. If this be not at hand, I set them under a few lights improvised to cover their heads on the north side of a wall or building, and where these are not obtainable I employ a piece of tightly-stretched thin canvas or white calico, sloping so as to throw off the rain, which, saturating the ball, frequently causes the buds to fall. In such a position there is also much less danger of the soil unobserved getting too dry, which is another cause of the buds dropping, although in both cases the effects of the injury may not be apparent until months afterwards, and the cause then forgotten. Such makeshifts as the above cost little in material or labour, and will preserve the plants from injury. But even dispensing with them, I can scarcely imagine a place where there is not a wall, building, or a few trees, on the north side of which Camellias can be set where they will be shielded from the sun during the middle of the day. In bushy dense growth, healthy condition in every way, size and profusion of flowers, there are thousands of examples to be seen throughout the country that I think afford sufficient evidence that the system of management with shade during the summer months of the year, hitherto admitted to be the right treatment for Camellias, is not likely to be surpassed by full exposure to the sun. Even when the leaves were not actually injured, I never saw Camellias fully exposed out-of-doors that had not more or less yellow colour in the foliage, not only unpleasant to look upon, but also an indication of want of good condition.—T. BAINES.

—If "Enquirer" (p. 466) cultivates his Camellias in the same way as we do, I can assure him that exposing them to the sun, either in or out-of-doors, during the greater part of the summer will do them much more good than harm. The Camellias which bloomed best with us during the past winter were specimens planted out in the conservatory; but all the lights were off the house last year from May to October, and, as will be remembered, the sun was exceptionally powerful last summer. I am of opinion that the less all plants that have either to produce fruit or flowers during winter are shaded in summer the better. I am not so fond of shading now as I was at one time, as I have frequently of late strongly suspected

it to be injurious. It is not the general exposure to the sun which causes the foliage of Camellias to blister, nor is blister confined to Camellias. On the contrary, it may often be seen on Vine and Pine leaves; and, indeed, on nearly every plant grown under glass. Bad speckled glass is the sole cause of blister, as any one may prove who will examine the roof of a glass house under which blistered leaves occur when the sun is out; a bright spot, like that produced by a lens, will be seen on each blister. We have sometimes found these specks so powerful that a match could be ignited under them at a few yards distant from the glass on a bright day. Therefore if they will do this no one need be surprised if leaves are blistered. Rather than shade the whole roof of a house glazed with speckled glass, we have had the specks all dabbled over with white paint, and this has effectually prevented burning while it did not exclude much sunshine.—CAMBRIAN.

BEGONIA ABEL CARRIÈRE.

THIS is the result of a cross between *B. discolor* and *Rex*, *discolor* being the male parent. *Rex* and its varieties are mostly stemless or nearly so, and have persistent variegated leaves which are continually being reproduced; the roots, too, are fibrous or filiform. *B. discolor*, on the other hand, is tuberous, caulescent, and has leaves uniformly green on the upper side and red on the under, whence the

Begonia Abel Carrière.

specific appellation *discolor*; moreover, the stems, and consequently the leaves, are annual. It will therefore be seen that these two plants differ greatly, both in appearance, mode of growth, and general character. The hybrid in question is the result of crossing these two very different species, and it participates in the characteristics of both its parents. It has the aspect and growth of *B. discolor*, but with variegation and marbling on its leaves which remind one of *B. Rex*. Its habit of growth is also slightly modified, and its aerial portions last much longer than those of *B. discolor*. The roots, too, are fleshy and smaller, less so, however, than those of *B. discolor*, which form tuberous masses. As for the hardiness of this variety, we can say but little at present, but it will endure more cold than *B. Rex*. New varieties, crosses between *B. discolor* and *Rex*, produce bulblets like *B. Rex*, but in smaller quantities, and always much more slowly, a state of things which may explain the facility with which they may be kept in leaf during the winter. These bulblets are neither uniform in size nor form. The two species in question were crossed in 1875 by M. Svahn, who collected the seeds of the hybrids thus produced, and sowed them again the following year. From these seedlings were obtained eight varieties, which have been introduced into the market by M. Bruant, a horticulturist of Poitiers. One of these is the Abel Carrière variety, of which the annexed is an illustration. It is an upright-growing plant, with a straight, strong, fleshy-ramified stem, which with the leaf-stalks of

a red colour. It often reaches a height of 18 in., its general form reminding one of that of *B. discolor*. The upper surface of the leaves is silvery, marbled with rose, and the under side pale pink. The flowers are also pink, and closely resemble those of *B. discolor*.

This variety, in addition to its other merits, possesses the recommendation of being perfectly hardy, as the experiments of M. Bruant prove most conclusively. Ten plants of it were left out in the open ground at the beginning of last winter without shelter of any sort. In November, a hard frost, with the thermometer at nearly 3° Fahr. below freezing point, left their foliage intact, although the parent *Begonia discolor* was completely stripped of its leaves a long time before. Some days after, a cold of nearly 6° Fahr. below freezing point stripped them almost completely, a few leaves, however, remaining at the base. By the 25th of January, after having gone through a severe winter, during which the temperature sank several times to 18° Fahr. below freezing point, in spite of their being planted in very damp soil, they appeared to have passed through the trial unscathed. The eyes at the collar of the root were very apparent, being well swollen, and evidently in an excellent condition for an abundant growth. It would seem, therefore, that certain of these new *Begonias*, which remind one, owing to their variegated foliage, of their congeners in the hothouse, may be grown in the open ground with perfect impunity. Such addition to our list of hardy ornamental plants is a welcome one.—“Revue Horticole.”

Bright-flowering Cacti.—At this season the large-flowering Cacti are very showy, producing, as they do, large blooms, and, when properly treated, abundance of them. For either greenhouse or window culture they are well adapted, and not being very pretty objects when not in flower, they are very accommodating, bearing considerable adverse treatment if not making their growth, at which period, however, they should be well exposed to the sun and get a good supply of water. The soil best suited for them is a good rich sandy loam, not chopped up very fine, as the roots require plenty of freedom to creep freely through it; plenty of drainage to allow the water to pass off is also necessary. During the cold wintry days they should be kept almost dust-dry, as anything like a stagnant soil is certain destruction to the roots. They are easily propagated by means of cuttings. Any sized cutting is almost sure to grow. Cut off a piece of a branch, put it in sand, and in a few weeks it is rooted, when it can be potted, and will shortly make a good plant. They have quite a variety of colours, some of a bright crimson, others of a pink, while some of them are almost pure white. *Cereus Corderoyanus* is a bright scarlet, *C. Gordonianus*, a rose-coloured one, and *C. crenatus*, a large-flowering, creamy-white, of good form, and well worth growing.—M. MITTON, in “Albany Country Gentleman.”

Mr. Peacock's Catalogue of Succulents.—We are informed by Mr. Croucher that certain printers' mistakes account for the errors in the spelling of the new catalogue, which, in any case, are of slight importance, and may be easily remedied in another reprint. The satisfactory thing is that the owner of the best and richest collection of succulent plants ever got together has published for the convenience of all interested in the subject a complete catalogue of his collection. If other amateurs were to do as much for their favourite classes of plants as Mr. Peacock has done for his, one could hardly imagine to what extent our garden wealth would grow. We do not know, however, a more unsatisfactory class of plants, because, do what one may, there is nothing will make the public take to their cultivation. At one time we could not understand this, and believed there was a future for them with the general public; but, notwithstanding the various effective ways in which Mr. Peacock has shown them to us, they do not seem to be more popular. We confess that there seems a reason for this, and that is the uniform aspect presented by them. They are, to a great extent, the same all the year round, and even Hawthorns or Roses could hardly withstand such a test as that. Yet there is one section which is deserving of attention from the cultivator, and that is, the kinds that flower freely and handsomely. As frequently grown, the Cacti do not flower in a remarkable degree; but some species, fairly well grown, flower in the most lovely manner, and Orchids themselves are not so exquisite in show of bloom as some of the flowering Cacti. It seems to us that if anything remains to be done by one who has already done so much for this strange family, it would be to make known or get together in some way the really fine-flowering kinds of Cacti, and there is nobody so well fitted to find out what is valuable in this way as Mr. Croucher.—R.

Todea superba.—A fine group of this elegant filmy Fern is now one of the leading features at the Pine-apple Nursery. A remarkable fact connected with these is that they have been subjected to as much as 14° of frost in an unheated house during the past winter.—W.

THE FRUIT GARDEN.

SWELLING OF FRUIT.

THERE is a considerable difference of opinion among cultivators as to whether size or weight in fruit are best attained by a comparatively high or low temperature. I saw it recommended some time since in a calendrical column to subject forced Strawberries to a temperature of 90° or 100° if high finish and size were desired, and in another contemporary I read that the best and finest-looking Peaches which appear at our horticultural exhibitions are those which have been subjected to excessive high temperatures during the swelling period. Is this so, may I ask? To me such advice seems to savour of inexperience, as those who follow it will find out. As regards Strawberries, I have always found that the fruit that was grown in a moderate temperature swelled to the largest size, and was also best in quality in every way. This also was the opinion of the late McEwen, who "swept the decks" as an exhibitor of forced fruit in his time. He was obliged to finish much of his fruit in stoves, but he acknowledged that the temperature of such structures were too high. I see also that "S. D." objects to the exposing of the fruit on pot plants to the sun late in the spring, and he is quite right. When the weather is very dry and bright in April and May, fruit under glass will be of quite as good quality and superior in appearance if its back is turned to the sun about the time when it begins to colour. I have done this many a time. As to Peaches and Nectarines, I have always found that those forced early or pushed on under a high temperature were the lightest by a good deal, while outdoor fruit, if well matured, was the heaviest, the size being equal in both cases. It is often necessary to push crops on in a higher temperature than is desirable, but moderate temperatures should prevail where practicable. It is much better to start sooner than to force vigorously towards the end.

It is just the same with the Pine-apple. This struck me very much a number of years ago on one occasion when, in order to meet a large demand, about a couple of score of Pines were treated differently to fetch them in together—one lot was pushed on in as high a temperature as they would stand, and the other and earlier lot was held back and allowed to swell leisurely, to end with plenty of air. The fruit of the last were not only the finest-looking, but the heaviest by a good deal. I tested the fruit in the scales, and found in one case that the hurried fruit was about half-a-pound lighter than the other, both being of the same size. I have frequently proved the same thing since.

These are facts of some importance to those who sell their fruit by weight. I am not so sure about Melons, but probably the rule holds good in the case of all fruits. Nor is the reason far to seek, and physiologists corroborate what practice demonstrates. A certain degree of heat is, no doubt, necessary to the production of fruit of the highest quality, but when this figure is exceeded it is at the expense of solidity of tissue, which requires time to form. Hard forcing may cause distension, but it is that kind of distension which we see in a bladder—hollow. The effects of a too high temperature are well exemplified in the case of the Pear previous to the stoning period. There is nothing more certain than that the crop can be made to drop at that stage by simply raising the temperature to a certain point. After stoning this result would not happen, but premature ripening would be the consequence, and the difference is only one of degree. We notice, as regularly as the season comes round, that the largest and finest fruit is always that furthest removed from the hot end of the house or furthest from the pipes, and is generally on the top of the tree where the last fruit ripens.

J. S. W.

FRUIT GROWING IN ENGLAND.

Now that the export of American Apples is becoming an important business for fruit growers everything connected with the subject becomes a matter of interest to them. A discussion on the growing of fruit for market in England has recently taken place in the *LONDON GARDEN*, from which we gather the following statements, and which naturally have some bearing on the character of the foreign market: A correspondent of that journal says that the demand for fruit in England has increased during the past few years "to an enormous extent." It always finds a ready sale. Notwithstanding the cheap and quick transit from the Continent, and the excellence of the Apples from America, the extension of fruit culture is on the increase. We are told by one writer that about 30,000,000 dols. are annually paid to other countries for imported fruits. Another correspondent of the same journal says that nearly 50,000,000 dols. were expended last year for fruits and vegetables imported into England. It is supposed that the city of London consumes about a million, and a half. We are informed that England receives fifty times as much as fifty years ago, the prices varying but little at the two periods. It

appears that the same trouble occurs there as in this country, namely, low prices and a want of demand in abundant seasons, and large quantities rot when the market is over-stocked, and the prices do not pay for gathering. The mode of preserving by canning, so extensively adopted here, is recommended in that country in such cases. One of these correspondents states that in Kent first-class Keswick Codlings brought only fifty cents per bushel, and of this sum one-half was paid for conveyance to market and expenses. Another correspondent says that many of the market gardeners near London left tons of Plums to fall and rot on the ground in 1875, the market being overstocked with fruit from the Continent. The same writer mistakenly asserts: "The American fruit grower, who obtains 400 bushels of Apples every year from his rich, cheap soil without manure, and with a minimum of labour and cost, can easily compete with the English grower, who pays an annual rent equal to the whole purchase money of his competitor's land, and has to spend as fully as much more in manure and labour; but if the Western grower should, by fertilising his land, double its yield, the extra 400 would not be grown at a profit." American orchardists, who have adopted the same opinion as this writer, are the very men who make fruit growing a failure. Their second-rate, scrubby, knotty Apples find a slow sale at a low price. Those who, with good culture, manuring, thinning, assorting, and careful packing, place the finest specimens before purchasers, obtain good prices and ready sales, and as soon as their products become known, they are eagerly sought on account of their excellent quality, even in abundant seasons. In looking toward a European market it would be extreme folly to attempt to send bad fruit that long distance with the expectation that it would pay expenses, and the damage to the reputation of American fruit, caused by such shabby attempts to thrust poor fruit on purchasers, would be many times greater than any possible gain.—"Country Gentleman."

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JUNE 10.

THE plants exhibited at this meeting, though by no means numerous, comprised several interesting novelties, to some of which first-class certificates were awarded. These were—

Cattleya McMorelandi (Veitch).—A superb variety, with large blossoms having sepals of a delicate blush tint, and a shallow lip much crisped at the margin, and blotched with bright orange.

Begonia Mrs. Arthur Potts (Veitch).—A beautiful variety in the way of the fine Peruvian B. Davis, but the blossoms are much brighter in colour, and produced more abundantly.

Gloxinia Yakob Khan (Veitch).—A handsome form belonging to the erect-flowering section. The blossoms, which are large, have a spotted throat and a broad ring of rich purple on the limb, copiously spotted with the same colour on a white ground.

Ochna multiflora (Williams).—A remarkable stove shrub shown in a fruiting stage, from four to six green Pea-like fruits being placed on a bright red fleshy disc surrounded by reflexed calyx segments of the same colour.

Imantophyllum concinnum (Williams).—A beautiful Amarylloid, similar in habit to the old I. Aitoni, but with blossoms of bright orange-red colour.

Begonia Marie Bouchet (Laing).—A splendid double-flowered variety which has elsewhere received the same distinction twice previously, and which has been already described.

Begonia Clovis (Laing).—Another superb double-flowered kind, similar to the preceding, slender in habit, and having large finely-formed blossoms, with deeply-toothed petals, very bright in colour.

Begonia J. H. Laing (Laing).—A fine addition to the single-flowered forms, being remarkably robust in habit and free flowering, the flowers being large, good in form, and bright in colour.

Begonia Souvenir de Gand (Osborn).—Also a kind of sterling merit, and well deserving of the distinction which was conferred on it.

Pelargonium Nellie Hayes (Hayes).—A robust variety, good in habit, and bearing large trusses of delicate pink blossoms, with blotches of a deeper shade.

Pelargonium Maid of Kent (Hayes).—A very useful variety, similar to the P. Duchess of Bedford, but of a better habit, freer flowering, and of a more delicate tinge.

Saxifraga Wallacei (R. H. Society's Garden).—A handsome Alpine, allied to the fine Algerian *S. mawana*, but freer, both as regards growth and flower, and more amenable to cultivation.

At the last meeting the following hardy plants were also certificated, but overlooked at the time:—

Primula sikkimensis (Dean).—A herbaceous variety with long narrow leaves and pale yellow bell-shaped pendent flowers, produced in scapes, on tall stems; a very distinct and pleasing variety, and perfectly hardy.

Polyanthus superbus (Dean).—A full border variety, having large scapes of flowers of good form, the eye clear lemon; ground colour, deep maroon-crimson, shaded off like an Auricula.

Miscellaneous Plants.—Of these Messrs. Veitch & Sons exhibited a choice collection, the most noteworthy amongst which were the beautiful white-flowered *Cattleya Wagneri* and the lovely *C. Mossii* delicata. The ornamental *Torenia Fournieri* was shown in this collection in fine condition, and displayed its distinct erect habit admirably, contrasting well with the yellow-flowered *T. Bailoni*. From the same establishment came also *Geniera Cheloni*, a remarkable hybrid between *G. macrantha* and *Dolichodora tubiflora*. The blossoms are tubular and from 2 in. to 3 in. long, of a pale flesh tint, and downy on the outside. A pretty white-flowered variety of *Weigela* (*W. hortensis nivea*) was also exhibited, and though the specimen was small, it was enough to show that eventually it will be a very desirable plant. A remarkably handsome *Lilium*, bearing the name of *L. bulbiferum aureo-variegatum*, was shown by the same firm in fine condition. Its flowers, which are produced in umbels, are of a bright orange-red colour, with the margins of the petals of a paler hue. *Rhododendron Prince Leopold* and *Duchess of Teck* were likewise very attractive; also the brilliant little *Begonia Davis* and the elegant *Begonia elatior*; the showy *Dendrobium Bensoni*, *D. tortile*, with its singular twisted sepals, and *Cypripedium Parishii* were also conspicuous amongst the Orchids; and amongst plants remarkable for their singularity were the *Arum trilobum*, with trilobed leaves and flowers, with a chocolate-coloured spadix and purplish spathe, and *Beckia astartoides*, an interesting shrub with Heath-like foliage and numerous small white flowers. From Mr. B. S. Williams, Holloway, came, in addition to those already alluded to, the rare *Cymbidium Parishii*, an Orchid described elsewhere in our columns. Messrs. Osborn & Sons, Fulham, contributed a collection of hardy plants, amongst which were *Saxifraga Wallacei*, *Anthericum liliastrium*, the charming Alpine *Myosotis rupicola*, *Iberis saxatile*, the white-flowered variety of *Erimum alpinum*, and others. The same firm also exhibited cut blooms of hardy *Azaleas* in rich variety of colour. From Mr. W. Fisher, Woodlands, Clapham, came admirably-grown examples of *Saccolabium retusum* and *Dendrobium Falconeri*, to which a cultural commendation was awarded. Mr. Turner, of Slough, sent good plants of *Polygonum Illuminator*, a superb new kind, having brilliant cerise blossoms with a white eye. Messrs. J. Laing & Co. showed, in addition to the *Begonias* mentioned above, *B. Kosy* Box, *Maude Churchill*, and a collection of cut blooms of *Pansies*. Of the latter a choice exhibition also came from Mr. Fleming, Berwick, which received a cultural commendation. Mr. G. Lee, Clivedon, sent cut blooms of *Viola argentea*, which were rather large, and of a greyish-blue tint. A form of the white *Lilac* was exhibited by Messrs. Paul & Son, Cheshunt, which showed a great improvement on the original, both as regards size of flowers and their abundance. From the Society's gardens was sent a collection of Cape *Polygoniums*, many of them original species. *P. Schottii*, with its very rich-coloured blossoms; *P. crispum*, *P. cuculatum*, and *P. ignescens* were amongst the most noteworthy. From the same source also came examples of the exquisite *Saxifraga lantoscana* and others; also cut blooms of *Begonias*, one flower of which (*Nellie May*) was unusually large, and of a pleasing rosy hue. Cut flowers of seedling *Columbines* were also shown from Chiswick, and afforded a striking instance of the many hues which the seedlings of this variable plant assume. Some admirable examples of a species of *Rhododendron* from Bhotan were also shown in the form of cut blooms, which were large, and varied from white to a rose tint. *Choretia glauca* was also exhibited in flower by Mr. J. Burnett, The Deepdene, Dorking. It much resembles *Pancratium speciosum* in general appearance, but the umbels are fewer flowered. It is no novelty, but its flowering is of a somewhat rare occurrence.

Fruit.—About half-a-dozen Melons only engaged the attention of the Fruit Committee. These were contributed by Mr. Miller, Clumber, who showed a green-fleshed netted Melon named *William Tillery*, to which a first-class certificate was awarded. The same exhibitor also sent a variety named *Clumber*. Mr. J. Atkins, of Wantage, also sent Improved *Colston Basset*; and Mr. Johnston, Bayham Abbey, *Freeman's Luscious*.

ROYAL NATIONAL TULIP SOCIETY.

THE closing days of the great Whitsun exhibition at Manchester were enlivened by the annual show of this Society, which took place in the Botanical Gardens, Old Trafford, on June 5. At one time it was feared the show of Tulips would be a very poor one, but the change to mild, growing weather on the 29th ult. greatly helped the development of the flowers, and they grew into size and coloured with remarkable rapidity. The best blooms were decidedly those of the Rev. F. D. Horner, Kirkby Malzeard, Ripon, who had taken the precaution of covering his bed with a glass erection, and thus brought on his flowers with more rapidity than would otherwise have been the case; the next most successful growers were Mr. Thomas Haynes, of Derby, and Mr. William Whittaker, of Salford.

The show was larger than was expected, and the flowers, on the whole, large and well marked. The champion prize, that of a cup for the best twelve dissimilar blooms, two feathered and ten flamed flowers of each class, was won by the Rev. F. D. Horner, who had Madame St. Arnaud, Dr. Hardy, Commander, Modesty, Mrs. Cooper (a beautiful new feathered byblomen of rare quality), Talisman, Demosthenes, Duchess of Sutherland, Bessie, Mabel, Ajax, and Mrs. Lomax. Modesty, Bessie, Commander, Madame St. Arnaud, Dr. Hardy, Talisman, and Mabel were in beautiful form, pure and well marked. The second prize was taken by Mr. Thomas Haynes with Aglaia, Dr. Hardy, Mrs. Lea, George Hayward, Queen of the Universe, Helena Mary, Duchess of Sutherland, Mrs. Lomax, Adonis, and Sir Joseph Paxton. Sir Joseph Paxton, shown in its feathered as well as flamed form; Helena Mary, Dr. Hardy, Aglaia, and Adonis were finely shown. The Rev. F. D. Horner had the best stand of six dissimilar Tulips, one feathered and one flamed of each class; he showed Talisman, Mabel, Commander, Sir Joseph Paxton, Mrs. Cooper, and Barlow's Bion, Mr. Thomas Haynes being second with Sir Joseph Paxton, Aglaia, Heroine, Bessie, Sulphur, and Violet Amiable. Mr. William Whittaker was third. There is always a similar class for half-guinea subscribers, and this is provided to give those having small collections a chance to win a prize. The first was taken by Mr. H. Houseley, who had good blooms of Lord Byron, President, Mabel, and Violet Amiable, the latter two being shown both feathered and flamed, Mr. R. Yates, of Leigh, being second. The best three feathered and the best three flamed flowers came from the Rev. F. D. Horner, who had in the first case Mrs. Cooper, Storers' No. 6, and Heroine; and in the second Lady Sefton, Adonis, and Orion. Mr. Whittaker came second with three feathered Tulips, viz., Adonis, Mrs. Lea, and Masterpiece; and Mr. T. Haynes was third with three flamed Tulips, viz., Aglaia, Sir Joseph Paxton, and Bessie. In the class for two Tulips, the Rev. F. D. Horner was again first, with Dr. Hardy and Modesty; and in the maiden growers' class for the same number of flowers, Mr. James Turner was first with Abbot's Gem and Aglaia. In the class for the best feathered and flamed Tulip in each class, six classes in all, a goodly number of flowers was staged, as ten prizes were awarded in each class, making sixty in all, with the exception of the class for feathered bizzars. The Rev. F. D. Horner took the first prizes in all the rest, Mr. T. Haynes being first in the former class.

Prizes were also awarded for breeder or unbroken Tulips. These were very beautiful in their self-form, and where large, pure, and finely tinted, they were highly attractive. In the class for six breeders, two of each class, viz., bizzars, roses, and byblomen, Mr. T. Haynes was first, with Dr. Hardy, Talisman, Mabel, Adonis, Madame St. Arnaud, and Mrs. Lea. When these break or rectify, it will be into the character of the Tulips whose names they bear; but some may be of a finer strain than others. The Rev. F. D. Horner came second, with Alice Grey, Music, Annie McGregor, Dr. Dalton, Lady Grosvenor, and William Lea; Mr. D. Barber was third. The best three breeders also came from Mr. T. Haynes, who had Madame St. Arnaud, William Lea, and Alice Grey; the Rev. F. D. Horner was second. There were also classes for the best rose, the best bizzar, and the best byblomen breeder.

The premier feather flower was Mrs. Cooper, from the Rev. F. D. Horner; the premier flamed Tulip, Sir J. Paxton, from Mr. T. Haynes; and the premier breeder Tulip, William Lea, from Mr. David Barker.

National Rose Society.—A meeting of the General Committee was held at the Horticultural Club on Tuesday, when some brief hints on the culture of Roses were agreed to; these will be circulated amongst the members and the different societies which have affiliated themselves with the National Society. Arrangements for the Crystal Palace exhibition were also made.

Erratum.—It was inadvertently stated in our report on the Whit Monday show at South Kensington that the first prize for fifty pots of Musk was awarded to Mr. Reeves, of Acton; it should have been to Messrs. J. & J. Hayes, of Edmonton.

OBITUARY.

DR. MOORE.

ALL who know anything of the horticulture of Ireland will learn with great regret of the loss of its most distinguished exponent, for Dr. Moore and Glasnevin have long led the horticulture of Ireland; few reputations were better deserved, as Glasnevin is a beautiful and richly stored garden, and David Moore was the beat ideal of a curator or director, which title he recently obtained. Always active and vigorous, full of enthusiasm for plants in recent years as much as in his younger days, he yearly continued his travels throughout Europe in search of beautiful or rare plants for his garden. Now in Sweden, now in Austria, another year in the south of England—anywhere where there was a botanic garden or a fine collection of plants, David Moore was sure to be there sooner or later in quest of interesting subjects for Glasnevin. The stay-at-home curator is sure to have a poor garden, and Dr. Moore was most wisely allowed the fullest liberty for travel, and took advantage of it in a way most profitable to the Garden and Ireland. Death has lately been busy in the ranks of leading horticulturists. It is sad to record within such a short time the loss of many of the most distinguished men connected with our great gardens—McNab, and Moore, and Niven, of Drumcondra, all within a short time of each other. David Moore was one of a band of young Scotch gardeners who, judging by their work and their progress in life, certainly were men of which any country might be proud, and included the energetic Niven, of Drumcondra, the Curator of Glasnevin before David Moore; Fraser, the eminent landscape gardener, and author of a well-known guide to Ireland; and the dignified and much-esteemed Wilkie, of Phoenix Park, Dublin, all now no more.

Dr. Moore was a native of Dundee, and in early life commenced his career as a gardener in the gardens of the Earl of Camperdown, at Camperdown, near Dundee. He afterwards went to the nurseries of the late Mr. James Cunningham, at Comely Bank, Edinburgh, where he remained till 1828, when he left to take the appointment of assistant to the late Dr. Mackay, Director of the Dublin University Botanic Garden. Under such a master all young Moore's tastes for natural history were cultivated, and he rapidly became an authority on the Irish plants. About 1834 the Ordnance Survey of Ireland was commenced, and David Moore was appointed on it. In 1837 the first volume of its memoirs was published, under the title of the "Ordnance Survey of Londonderry," and contained a memoir on the geology of this district by Captain Portlock, on its political and antiquarian history by George Petrie and J. O'Donovan, and on its botany by Dr. Moore. This was Moore's first contribution to science, if we except the assistance he gave to his old master, Dr. Mackay, in the production of the "*Flora Hibernica*," an assistance gratefully acknowledged in the introduction to that work. The projected survey of Ireland was, however, commenced on far too elaborate a scale to be in like manner continued; and although a vast amount of material was collected towards elucidating the history of others of the Irish counties, yet these were never published, and the botanist of the survey soon after this date resigned his post, and was elected Director of the Gardens at Glasnevin, then belonging to the Royal Dublin Society, with the improvements of which the name of Dr. Moore will ever be connected. Often hindered for want of funds, with but few sympathetic spirits to cheer him on, the Doctor laboured long and hard, until he has, as now, made these gardens to hold their own amid the gardens of Europe. Pleasantly situated by the bank of the little Tolka, associated with the memories of Tickell, Swift, and similar men, Nature has done much for them—the gardener's art but little.

It is now a story—too well known to need repeating—how Moore, working in unison with Nature, made these gardens useful to the practical gardener as well as to the botanist and citizen. Many of our readers will recollect the numbers of new plants first introduced to our gardens from Glasnevin, the numbers of interesting plants first flowered or fruited there, and the numbers of new hybrid forms first raised there. Of Dr. Moore's more original botanical work we can here only mention the "*Cybele Hibernica*," undertaken conjointly with A. G. More, F.L.S.; his works on the Irish Mosses; on the Irish Liverworts, and on the Irish Grasses. For a record of his practical researches, of his many tours to Russia, Italy, Spain, France, Germany, and Norway in quest of botanical information, we have left ourselves no space. He was a member of the council of the Royal Irish Academy, whose president, Sir R. Kane, at the meeting last evening expressed deep regret at his death, and observed that he had contributed most valuable and interesting memoirs upon vegetable physiology and upon the botany of Ireland. He was also a member of the Linnean Society, and a corresponding member of the leading botanical societies of Europe. He died early last Monday

morning in the Garden, and was interred at Mount Jerome Cemetery at Dublin on Wednesday. He was for more than forty years curator and director of the Royal Botanic Gardens at Glasnevin, and was for some time assistant examiner in botany in the Medical School of the University of Dublin. As a recognition of his services, the University of Zurich conferred upon him the degree of Doctor of Philosophy in 1865.

The Dublin "Daily News" of the 18th inst. says that, "Dr. Moore's eldest son is Curator of the College Gardens, Dublin, and, since his appointment to that post, has given unqualified satisfaction to the board of that college and the medical professors who visit the gardens and its collections for their lectures. Up to a few days before his death Dr. Moore was a man of very active habits and excellent health. On Friday, feeling some unpleasant symptoms, he called on Dr. Butcher, who carefully examined him. His ailment turned out to be a very serious one, and the severity of the symptoms increased with alarming rapidity. Dr. Butcher was unremittent in his attentions, but no care or skill could avert the fatal end. Dr. Moore expired on Monday at 2.30 a.m. We presume that his eldest son, an accomplished practical botanist, carefully trained at Glasnevin and afterwards in some of the most famous foreign schools, will be promoted from the curatorship he now holds to the more valuable post held by his lamented father."

H. NOEL HUMPHREYS.

It is with deep regret that we have to announce the death, on Tuesday morning, the 10th inst., of Henry Noel Humphreys, who, although only, as one might say, an occasional worker on horticultural subjects, was long known in connection with them. After considerable artistic training in early life, he, at a time when art was not so much a fashionable profession as at present, deserted it for literature; but, before doing so, he had already, when a very young man, done many beautiful drawings of plants for a publication issued in connection with the Birmingham Botanic Gardens nearly fifty years ago, the name of which, for the moment, escapes us. Years afterwards, friendly with the Loudons and related to them by marriage, he again took up botanical drawing for a time, illustrating Mrs. Loudon's well-known works on the "Flower Garden," "Hardy Bulbs," &c., books most successful in their day, and still on the library shelves of many lovers of plants. He was very intimate with Mr. Loudon when he lived in Porchester Terrace, Bayswater, and wrote some memorials of him in *THE GARDEN*. Then came a long interval of active literary and other employment, and a total severance from any horticultural work, until the time of the appearance of Moore & Ayres' "Magazine of Botany," which was illustrated by some beautiful sketches from his pencil. At that time, and several years before, he was acknowledged to be one of the most graceful artists on wood in London, and much sought after by publishers and authors requiring tasteful work in that way. Again, after a considerable lapse of years, he undertook the drawing of a number of beautiful Alpine flowers, intended as the first series of a work on the subject. To do this he remained at York for nearly two months and made a series of studies, which are admitted by all who have seen them to be very beautiful, and in which he has caught well the delicate grace and exquisite beauty of these flowers. In this case, for the first time, so far as we know, in drawings of the kind, the plants were drawn not merely in detached portions, which is the rule in books, but as they grew on the rocks with their surroundings of Moss and other minute plants, so that one gets an accurate idea of their size and character, as well as of the beauty of the individual parts. No man could have devoted more painstaking and loving attention and precious time to a work of this kind than did Henry Noel Humphreys. His early love of drawing plants being once revived, he continued that work till a day or two before his death, making studies from plants gathered in the gardens round London, and frequently drawing a plate for *THE GARDEN*. This slight sketch of his labours in one direction may serve to give a feeble notion of the wondrous activity of the man in other and in different directions, some of which have no relation whatever to our art. He travelled much, making many landscape and other sketches on his way, and was an excellent linguist. Those who knew him in early life speak of him as one of remarkably bright parts and ready wit, qualities which he retained to the end. His abilities and devotion, to anything which he took in hand were such, that the results could only be appreciated by those who knew in how many diverse ways his energies were devoted. He died at his house in Westbourne Square after an illness of but a few days, aged seventy-two years. He was born at Birmingham, and educated at King Edward's Grammar School and in Brussels. After a residence in Rome, he, in 1840, published his first work, the descriptions to "Views in Rome," by W. B. Cooke. He was joint author with Mr. J. O. Westwood of "British Butterflies and their

Transformations," published in 1840; of "British Moths and their Transformations"; and author of "Illuminated Illustrations of Froissart's Chronicles," in 1843; of "The Parables of our Lord" (Illuminated), in 1846; of "The Illuminated Books of the Middle Ages" (folio), and "The Art of Illumination," in 1849; of "Ancient Coins and Medals," illustrated with fac-similes of Greek and Roman coins, in relief, in 1850; of "The Collector's Manual," in 1853; of "The Coinage of the British Empire," in 1854; of "Stories by an Archaeologist and his Friends," in 1856; of "Ocean Gardens," in 1857; of "Butterfly Vivarium, or Insect Home," in 1858; of "Göthe in Strasburg: a Dramatic Novelette," in 1860; of "Holbein and the Dance of Death," in 1868; of "A History of the Art of Printing," in 1867; of "Masterpieces of the Early Printers and Engravers," published in 1870; of "Rembrandt and his Etchings," in 1871; of several novels, published anonymously, and of tales, magazine articles, and other works, and numerous contributions to journals.

Canon Beadon.—We have also to record the death of that veteran horticulturist, to whom allusion was lately made in THE GARDEN, viz., the Rev. Canon Beadon, Rector of North Stoneham, near Southampton, which took place on Tuesday last, at the great age of 102. He was born December 8, 1777, and it will be remembered that Her Majesty wrote him a letter on his attaining his hundredth year.

EFFECTS OF THE WINTER.

AMONGST the uninjured in the gardens here may be mentioned all the kinds of Pinus, including excelsa and insignis; all sorts of Picea, including nobilis, magnifica, amabilis, cephalonica, lasiocarpa, Nordmanniana, Pinsapo, and others; Cedrus atlantica and Libani; Abies Douglasi, Menziesi, polita, canadensis, and orientalis; Retinospora obtusa, pisifera, filicoides, squarrosa, plumosa, and plumosa aurea; Cryptomeria japonica; Araucaria imbricata; Torreya myristica, very slightly browned; Cupressus Lawsoniana, L. evicta, and L. aurea; Chamaecyparis spheroides variegata; Cephalotaxus Fortunei, and drupacea; Juniperus chinensis, c. aurea, drupacea, occidentalis, phoenicea, virginiana, and v. glauca; Prunopitys elegans; Thuioopsis borealis and dolabrata, this last even greener than usual; Thuja various, these also wonderfully fresh; Biotas, all fresh; Cerasus lusitanica and laurocerasus, Wellingtonia and Cedrus Deodara, some of the tips of which are browned; and Hibiscus syriacus. Amongst the damaged are Magnolia grandiflora, Cryptomeria Lobbi, Sequoia sempervirens, Cupressus macrocarpa, Phyllyrea angustifolia and latifolia. The killed consist of Verberna triphylla, Ceanothus aureus, Myrtus parvifolia, Eucromocarpus scaber, all of which survived the winter of 1877-78; Escallonia macrantha; Cupressus lusitanica, Corneyana, and sempervirens, but this last had been recently moved.

ANON.

—Effects unaccountably variable as regards the winter show themselves even in the same localities. Large Bays on dry, sandy soil, even under the immediate protection of high walls in the northern counties, are in some places killed down to the ground, whilst in others not far distant they are little injured. Hollies have had their last summer shoots killed back, and are half denuded of leaves. In one garden all the Pampas Grass is killed outright, or nearly so, and in another garden adjacent this and other plants are little the worse. In one large establishment in the midland counties, many Wellingtonias, planted when first the tree was distributed, are either killed, or so far injured as to be worthless. Cedrus Deodara has suffered severely, whilst, standing close to it, Cryptomeria japonica is as green and fresh as if we had passed through a mild winter. These are only a few instances of the many that have come under my notice of the very partial effects left by the late severe and protracted winter.—P. G.

—The following is the condition of hardy and half-hardy plants and shrubs near the shore of the Atlantic in Cornwall: Killed—Abutilon striatum, Aster argophyllus, Calceolaria aurea floribunda, Cassia corymbosa, Escallonia macrantha, Eucalyptus globulus, Fuchsias (all killed to ground), Pelargoniums (various), Locust tree, Physianthus albidiflorus, Polygonum complexum (several), Spiraea Lindleyana, Veronica (several), Sweet Verberna (Aloysia citriodora), and almost the entire stock of frame plants and cuttings, except Verbenas and Chrysanthemums. Injured severely—Cornilla, Farfingium grande, Habrothamnus elegans, Myrtle, Rhododendrons (some), Veronica Andersoni, Vitex Agnus-Castus. Injured slightly—Camellias, in foliage (some), Eucyonium japonicum, E. variegatus-aureus, Laurel (some), Myosotis dissitiflora, Ozothamnus thysoides, Taxodium sempervirens. Escaped uninjured—Acacia dealbata, Berberis Darwini, B. intermedia, Boconia japonica, Chamaerops excelsa, Camellias (some), Cryptomeria japonica, C. elegans, Forsythia viridissima, Gunnersa bacca, Hydrangeas, Japanese Honeysuckle, Primula japonica,

Liquidambar, Louis Philippe Rose, Magnolia conspicua, Maclura aurantiaca, Rose Maréchal Niel (on south-west wall), Myrsine undulata, Paulownia imperialis, Phormium tenax, Symplocos japonica, Sciadopitys verticillata, Schizostylis coccinea, Smilax aspera, Thuja Doniana, Pinus austriaca, P. Pinaster, and P. insignis, three most valuable nurses, which suffered more or less in 1860-61, seem to have escaped uninjured in all situations this season.—J. J. ROGERS.

—Plants in the west of Ireland have suffered considerably; even at Killarney Arbutus and Fuchsia are cut to the ground. Such shrubs as Escallonia, Buddleas, and Laurustinus are much damaged, and the New Zealand Flax is killed. Glengwruff appeared to be the one favoured spot which had escaped any serious injury; the Fuchsia hedges which exist here were very little damaged, and in the charming garden attached to the Eccles Hotel it was hard to believe that there had been any winter at all; even the variegated shrubby Veronica was uninjured. In another garden, at the same place, there were some magnificent clumps of New Zealand Flax; one was 57 ft. in circumference, and only the tips of the outer leaves were browned. Near Dublin, I noticed that the Eucalyptus globulus, though killed to the ground, was pushing up fresh shoots, and I hear that this is also the case at Chislehurst.—A. K. EASTCOTT.

ROSES.

TO DESTROY MOSS ON THE BRANCHES OF ROSE TREES.—These Mosses or Lichens, which are frequently yellow, but oftener of a greyish-green, grow rapidly on Rose trees planted in the open air in heavy, damp soil, as well as on Briers after having been planted for two or three years in light soil. A rotten stake well grown over with Moss is apt to infest the Rose tree which it is supporting. These parasites are easily got rid of in the following manner: Stir up 1 lb. of quicklime in 6 pints of water, which will give a creamy liquid, with which wash the parts with an ordinary whitewash brush. Under this treatment the Moss and Lichens turn red and fall off at the end of a few days, carrying with them the layers of the old bark. The tree soon becomes improved when thus cleared of Moss and Lichen, which always harbour a large number of destructive insects and their eggs. This operation should be performed between the months of December and February, and keeps the trees cleared for upwards of three years. As most amateurs do not like to see their pet trees daubed over with whitewash, we may use lime water instead. This is prepared by throwing 1 lb. of lime into 3 gallons of cold water, stirring the mixture well with a stick, and allowing it to settle. The clear liquid alone should be used. It should be made and used at once, as it will not keep its strength longer than a couple of days. It may be applied with a whitewash brush or the syringe, which should be well washed after use. Instead of lime-wash, cement-wash may be used in the proportion of 1½ lb. of Portland cement to 8 pints of water, and may be applied with a whitewash brush, the syringe, or the garden engine.

WHITE FUNGUS.—This peculiar growth makes its appearance in the middle of summer, and only disappears with the first frosts. It grows in the form of a mass of white filaments, which cover the leaves, buds, and seed vessels with an irregular mass of threads. The leaves which are attacked with this disease speedily curl up, wither, and drop. I have proved that this disease is most rife in dry hot summers, and that Rose trees with a southern or eastern aspect are the first to be attacked. The varieties which are more particularly liable to this disorder are the Géant de Batailles, Caroline de Sansal, and the Lion des Combats. It is easily got rid of by sprinkling the trees with flour of sulphur as soon as the spores are seen upon the leaves. If the disease spreads it must be stopped by repeating the process three or four times. If it still makes head, the infected leaves and shoots must be rigorously cut off and burnt. In order to preserve the young seedlings from this disease, we must sprinkle them and the surrounding soil with flour of sulphur as soon as ever the first leaves begin to make their appearance. The sulphur which falls on the root plays its part in the cure by disengaging a certain amount of sulphurous acid which takes place at ordinary temperatures.

ROSE CANKER.—The Rose tree is frequently attacked by canker, a disease which is developed sometimes as the result of the bark of the shoots having been accidentally bruised, and in others from similar wounds formed by the branches chafing against each other. The prick of an insect will often bring it on, especially if it has deposited its eggs beneath the epidermis, the eggs producing larvae, which make matters worse by still farther disorganising the tissues of the bark. In either case we must thoroughly wash the wound, taking care to destroy the larvae if there are any to be found. The edges of the bark must be deeply pared away, and the new place well covered with a thick layer of grafting wax. J. LACHAUME.

ANSWERS TO CORRESPONDENTS.

Orchids.—I have on blocks several plants of *Oncidium Forbesi* and *Cattleya Mossiae* which are growing so strongly as to have pushed out beyond the edges of the block; and, fearing they may be injured, could you advise me how to make them grow back, so that they may look more compact and not so one-sided? Could they be cut partially through with a sharp knife, so that more energy may be thrown into the lower part? How could I cultivate the *Acanthophippium bicolor*? It grows very strongly, making three large bulbs every season, but I cannot induce it to flower.—ARGONAUT. [This is a difficulty often experienced when Orchids are grown on blocks, and it can in some cases be remedied by planting the lower part of the wood into a pot of compost, and for the same plants when grown in pots, and into which they are thus induced to root. In some cases the block itself may be enlarged with advantage by splicing or tying another piece of suitable wood to it firmly. The result of partially severing the rhizomes, as suggested, will be to induce the back pseudo-bulbs to break or throw out new growths. As the *Acanthophippium* grows so strongly without producing flowers, it is possible the growths do not become sufficiently ripened, to which end allow the plant more sunshine, and water sparingly when the bulbs attain their full size. A one-sided habit of growth is natural to a large proportion of all known Orchids, and especially of *Cattleyas* and other rhizomatous kinds, so that, to obtain compact and symmetrical specimens, one must either plant several individual plants in the same pot, or, what amounts to the same thing, induce the "back bulbs" to break by severing the rhizome between the pseudo-bulbs. It is so unusual for *Cattleya Mossiae* to grow strongly when cultivated on a block, that it would be interesting to know the size of "Argonaut's" specimens so grown, and their yearly proportion of bulbs, leaves, and flowers.—B.]

Roses at Cannes.—The foliage of the *Macartney Rose*, leaves of which have been sent to me, is quite different from that of the *Rosa Camellia*. The leaves of the latter are much larger, and have a gloss resembling that of *Camellia leaves*; neither is this *Rosa* at all like *Rosa rugosa alba*, except in the flowers, which are single. As I did not return home straight from Cannes, I regret that it was impossible to bring one of these *Rose plants* with me. They were for sale at the *Jardin Massieu*, which garden, I need not tell you, though small, is, I may so term it, a perfect curiosity shop of rare shrubs and plants, unfortunately crowded together that most of the finest are badly shaped, and I have great doubts if this *Rose* has been brought home, or, at all events, is to be purchased at an English nursery. I visited *Villa Franzolini*, Lake Maggiore (mentioned some years back in *This Garden*), and never saw anything before to equal the quantity of *Camellias* there; in fact, one approaches the villa through a grove of them, out I come to the opinion, after looking for some minutes on their tens of thousands of blooms, that one's eye rests with much greater pleasure on the tree *Rhododendrons*, which grow well in that district. The *Pinetum* at *Franzolini* contains the finest specimens of *Thuja gigantea* I have ever seen, planted in clumps of three. The trees at *Isola Madre*, too, are worth a visit.—J. H. THOMAS, Belmont, Carlisle.

Seedling Briers.—I have got a quantity of two-year-old seedling Briers which were more than a fortnight ago sent each to one of my old plants in rows in a shady border, and are of heights varying from 5 in. to 14 in. How soon will they be fit to bud? and should they be used for Hybrid Perpetuals as well as Tea Roses, or only for the latter? and, when the time comes, should the buds be inserted on the main stem close to the stem, or on a side branch? Seedling Briers will probably be ready to bud by the 20th July. Hybrid Perpetuals succeed equally well as Tea Roses on this stock. The buds should be inserted on the main stem as low as possible.—A. W. P.]

Gooseberry Caterpillar.—The ravages of the Gooseberry caterpillar this year almost equal those of the locust. Bushes a fortnight ago pictures of health and beauty are now skeletons, the almost total destruction of the fruit being threatened, and eventually the bushes. Is there any other mode of destruction besides hand-picking? Last year there were few or no caterpillars, and the bushes have had their usual top-dressing &c. [Sprinkling with lime, or spraying affected with freshly-powdered Hellebore when they are wet is said to be one of the best of the many remedies proposed for the destruction of this pest.]

Primula amœna.—We have received a few fine blooms of this beautiful Primrose grown out-of-doors in Mr. Nelson's garden at Norwich. They are of large size, the colours well defined, and in considerable variety, affording additional proof that it is quite amenable to outdoor culture.

Pelargoniums.—J. W.—Keep the plants in a well-ventilated frame, and, in the case of tricolours, keep the flower-buds pinched off, and treat the plants liberally. The same applies to the others you mention, except that the flower-buds must only be pinched off till within about a fortnight or so of the time when you require them to flower.

Seedling Petunias.—The blooms of the Double Petunia sent are very fine, the colours bright and distinct, and the flowers of good form and size, and pretty fringed, and they are very well worth growing and marketing.

Names of Plants.—C. R.—*Paulownia imperialis*. P.—*Tradescantia mundula*. G. R.—Apparently *Pavia californica*. A. E.—*Genista hispanica*.

Names of Fruits.—J. B.—Sir Charles Napier Strawberry.

Primulas.—A. J.—Enquire at some of the principal London nurseries.

Questions.

Southern Palms.—In a book of travel which I have been lately reading, a Palm is mentioned as growing in the mountains near Christchurch, Canterbury, New Zealand. From the name one would naturally suppose that *Kentia* (Canterbury) came from the neighbourhood, but I have been unable to ascertain that it was brought from Lord Howe's Island in lat. 31° S. *Areca* sapida is found in New Zealand as far south as lat. 38° S. Does it extend to the Southern Island? I also anxious to ascertain what is the southern limit of *Jubaea spectabilis* in Chili, and at what altitude it is found there. I shall be much obliged to any correspondent who can give me this information.—E. G. L.

Rhododendron Hardyana.—Who is the raiser or grower of this *Rhododendron*? The size of the truss is large and bold, and the colour nearly crimson. It has stood the late winter almost intact. Its foliage is almost perfect, though next to a Holly and Aucuba, which are some years in the habit of being on either. It would be invaluable to all wishing to grow *Rhododendrons* near a town and in a smoky atmosphere, which seems not to have the slightest effect upon it. I am within 2 miles of the Manchester Exchange.—W. A. S.

Mildew.—Can any of your readers help me to find a recipe against mildew in Roses, given, I think, by a late Rose grower in some of the public papers on gardening? It consisted chiefly of sulphur boiled over the fire in an earthen pipkin, and I proved so efficacious last year that I wish to make more, but have forgotten the particulars.—CONSTANT READER.

GARDEN LABELS.

WE noticed in Mr. Ewbank's garden at Ryde a label which differs from any other that we have seen, and which seems to have some very good points about it. A representation of it is annexed. The transverse part of the label is made of a small strip of wood, which is twice painted white and once black. The supports are made of stout galvanised wire, which fit into two holes on the lower edge of the

New Plant Label.

little piece of wood. The name of the plant appears in white letters, which are very easily scratched upon the black surface. Mr. Ewbank prefers these labels to those which are made of iron, because they are less cumbersome, and they cost with him not more than a fifth part of the iron labels. Also it is much easier to scratch a name upon wood than upon iron. They are better in his opinion than labels which are wooden throughout, because the lower parts of these latter are sure to decay in the ground. They have a great advantage over zinc labels because the writing on them is so very legible, and no wetting is required to make it plain. They are not injured by frost, or broken by a knock, which is so commonly the fate of labels when made of terra-cotta. Altogether, on the score of appearance, of duration, of cheapness, and of uprightness in the ground, these Isle of Wight labels are worthy of some consideration. A common carpenter makes and prepares, with three coats of paint, the little transverse pieces of wood for Mr. Ewbank at a rate which does not exceed 1s. 6d. per hundred. A pound of the galvanised wire can be purchased in Ryde for 4d., and any gardener can make the holes, and cut and fit in the supports on a wet day, or when he has nothing better to do. If these labels were made by machinery, the price could be brought down to a very low figure. Mr. Ewbank is taking to this form of label entirely, and he intends by degrees to exclude all others from his garden.

Sheltered Nooks.—These, when formed by boundary walls or low buildings, and not by shrubs or under the drip of trees, can be turned to account for protecting delicate plants which would be likely to suffer in severe winters from entire exposure, and are very useful for striking cuttings of *Pelargoniums* in the late spring and early autumn months. Last year most of mine were raised in a place of this sort, and for the protection that such a locality affords to the more delicate subjects that usually have to rough it in winter in the open borders, I can instance the case of the *Aquilegia cerulea*. This winter's cold killed all that were entirely exposed, but I have two now coming into bloom that were turned up to their rims about six weeks ago. They had been plunged up to their joints in the place already mentioned with no other protection whatever but the wall, 2 ft. from them. I have now above 100 cuttings of *Pelargoniums* there, some of which had to encounter the frosts in the early part of May, and not one appears to have suffered. I ought, perhaps, to describe the place, for it has peculiar features, rather favourable than otherwise, to the use to which it has been put. It is of a long and irregular shape, open at its north and south extremities; but there are some buildings, which, though they do not close the opening at the north end, afford protection from the keenness and violence of the north wind, and the sun's rays can only reach the little borders during winter in the middle of the day, but they are then scarcely felt, owing to some lofty trees whose branches intercept them for nearly half the year. This I consider to be no disadvantage, as it tends to keep vegetation dormant in this confined quarter, and excessive dampness is provided against by the free circulation of air. In striking the cuttings of *Pelargoniums* and *Chrysanthemums*, I usually, but not always, raise the height of the borders, and supply a little silver sand to the heel of each cutting when planted in this spot.—B. S.

WE learn that Mr. Head has been appointed successor to Mr. Thompson in the management of the horticultural department at the Crystal Palace. Mr. Head was formerly foreman in the flower garden department at Kew, and lately he held the post of superintendent of a garden in India.

Vol. XV.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE EARLY ALEXANDER PEACH.

VARIOUS notices have appeared in THE GARDEN respecting the existence of an American Peach said to be the earliest of all Peaches; this is the early Alexander. In 1876 I received from Messrs. Capps & Son, of Mount Pulaski, Illinois, two varieties which they described as being earlier and larger than the early Beatrice, which had been largely planted in American orchards; these two sorts are the early Alexander and the Amsden Pine. Although I have fruited the early Alexander, I have hitherto grown it principally with the view of testing it, but after the experience of three seasons, I may venture to say that it is a really valuable early Peach, good either for forcing or for unheated orchard houses, or for walls, and the fruit grower for market may plant it in the fullest confidence of realising a handsome return from it. The fruit is large, of a brilliant colour, and good in flavour, and it will ripen at the same time, and in some cases earlier than the early Beatrice hitherto the earliest Peach known. The early Beatrice, although remarkable for its precocity, is too small; the Alexander when well grown is as large as the Grosse Mignonne.

In a forcing house this year the Alexander ripened ten days before the Early Beatrice; but I do not attach much importance to this fact, as the position of a tree will alter the period of maturity very materially; but the fact is, nevertheless, important, as proving its precocity. In a letter received in July, 1878, from Messrs. Capps, they remark—"Our Alexander Peaches were large and beautiful this year; they were very highly coloured, and commenced ripening about the middle of June, and were all gone by the 10th of July." On walls in England it will probably ripen about July 20; in the orchard house it has ripened from the 6th to the 10th of the same month. I think it may be assumed that a fine early Peach is now in existence. The tree is hardy and grows vigorously; it has stood the severe test of the past winter as well as the hardest English varieties. The Amsden Pine, which I received at the same time, so much resembles the Alexander, that it is hardly necessary to grow the two sorts. The Peach season is now considerably prolonged, the Alexander, Early Louise, Hale's Early, Early Rivers, and Early York being an extraordinary advance upon the Early Nutmeg, Double de Troyes, Early Ann, and Acton Scott.

It is to be hoped that the refrigerating process will not be the means of inundating our markets with American Peaches, but I think there is good cause for thinking that the English grower will have to compete against the Transatlantic orchards, and therefore it may be necessary to select sorts that will ripen before the American harvest begins.

Sawbridgeworth.

T. FRANCIS RIVERS.

Vicomtesse Héricart de Thury Strawberry is the best general kind for pot culture.—A. D.

Strawberries and the Frost.—Not only are Strawberry plants not injured by frost when exposed to it previous to being forced in pots, but I am convinced that it does them good. All our Strawberry plants in pots here this spring have been unusually vigorous and fertile, so much so, indeed, that I must say that I never saw any pot Strawberries better, and yet the whole of them were frozen hard for weeks together, most of them only being "strawed" when placed in their forcing quarters. A few fruit of Black Prince shown early in March were admitted to be the best ever seen at that season of the year. Black Prince is not, as has been stated, "an inferior variety in all cases." Here it proves to be a very superior sort, and much preferred to many varieties often recommended.—J. MUIR, *Margam Park.*

BLACK ROT IN THE VINE.

IN this country and in America this disease is known by the expressive appellation of Black Rot. Unlike Oidium and the Phylloxera, it has not been imported into Europe at least within the memory of man. Its history appears to be coeval with that of all Vine growing countries, having been minutely described by all the earliest naturalists who have treated of the Vine. M. H. Mares, in his remarkable treatise on the Vines of the south of France ("Traité des Vignes du Midi de la France") gives a translation of a passage from "Theophrastus" which describes this disease in such striking terms, that no one can fail to recognise in it the Black Rot, which raged with such violence in so many Vineyards in France, Italy, Switzerland, and several other parts of the wine-growing zone in Europe. The antiquity of this pest has in no way diminished its virulence; it seems to have preserved its destructive character through a score of centuries, and differs in no way in the year of grace 1879 from what it appears to have been when the learned Greek wrote his immortal "History of Plants," some 350 years before the Christian era.

The first evil effects of the Black Rot generally make their appearance with the first shoots of the Vine somewhere about the middle of the month of May, and increase in intensity, according to the temperature and the variety of Vine, until the month of August, always attacking the young herbaceous shoots as well as the Grape itself from the time of its formation until it begins to ripen. Rainy weather, a fog, or a heavy dew appear to be amongst the principal causes of the disease, above all if damp weather alternates with strong sunshine; on the other hand, dry weather diminishes the mischief. Vines imported from hot countries, especially those which leaf abundantly, are particularly subject to the Black Rot, the indigenous Vines of the north and centre of France suffering much less. The foreign varieties which suffer most are the Greek Rosaki, noticed by M. Mares; the Asia Minor Chaouch, the Crujidero, the Lignau, the Insolia, and the Muscat of Alexandria. In the southern Vineyards, the Carignan and the Clairette are peculiarly subject to this disease. The first traces of it make their appearance in the form of little round specks or spots of a brownish-black colour. They are unequally distributed over the shoot, leaf, and Grape, upon all of which they appear simultaneously, as shown in the annexed woodcuts. These specks and spots enlarge, still, however, preserving their circular form, and passing from a dark brown to a black. They penetrate more deeply into the young shoot, and either check its growth or dry it up according to their number, and the conditions for their development being more or less favourable. If the attack is very severe the leaves and fruit follow the fate of the young shoot. If, on the contrary, the spots are few in number, and the conditions for their development are unfavourable, the young shoot grows up without suffering irretrievably from the injury; but for all this, the leaf and fruit may suffer very severely, seeing that the leaves and Grapes on a perfectly healthy shoot may be utterly destroyed by disease. These three parts of the Vine, the stem, the shoot, the leaves, and the Grapes are, however, more frequently attacked simultaneously by the black rot; but it also happens somewhat frequently that one or other of them are preserved from the evil according to their state of health as well as to the resistance they can make to the attack of the enemy. When these spots implant themselves on the ribs of the leaf before it has attained its full development, it twists it up, curving it over on its under side, causing it to perform its functions only very imperfectly. As for the fruit, it may be a prey to the disease at any time from its first formation, even before the flower is formed, to the moment it enters on maturity. When once the skin becomes tender the disease has no longer any evil effects upon it.

As for the leaf, as in the case of the fruit, the damage done becomes more serious, and ends most frequently in the drying up and death of these organs as soon as the disease reaches the stalk of

Vicomtesse Héricart de Thury Strawberry.—My remarks upon this Strawberry for pot culture (p. 441) were well borne out by the plants from Chiswick shown at the great exhibition held at South Kensington last week. Better fruited plants it would have been difficult to produce, as of the dozen staged all carried from twenty to twenty-five fine ripe fruits, richly coloured, and fit for any table. With them were staged a few plants of the new Early Proflic of the Sir Charles Napier type, but although the fruits were a trifle larger, they were not so well coloured, and produced not more than one-half the crop. Properly grown, and that is easy enough,

either of them. These black spots which cause such damage to the Vine have some sort of analogy with those which we find on the leaves and fruit of the Pear and Apple. The latter make their appearance under precisely the same circumstances as those on the Vine. They never apparently seem to attack the wood, and they rarely cause the death of the leaf, although they may injure it, but they produce a kind of gall upon the fruit, which may harden the skin and sooner or later cause the fruit to rot. As we have already remarked above, damp or wet weather, heavy dews and fogs, always precede these attacks of Black Rot, and appear to be amongst the principal conditions of its development. A Vine which can be protected from rain, dew, and fog is never attacked by this pest. One fact which we shall quote will prove this assertion most conclusively. We have now growing in the rich soil of our kitchen garden a strong healthy stool of the Agastenga Grape, which has formed three separate cordons. The first of these is trained vertically against an east wall, and covered by a movable shelter, which projects from the wall some 12 in. or 16 in.; the second is trained horizontally against an unsheltered wall with a southern aspect at a distance of some 8 in. above the soil; while the third is trained as an espalier at a couple of yards distance from the preceding. The third cordon shows every trace, more or less serious, of having been attacked by this disease. In 1877, for instance, its fruit was completely destroyed by successive attacks of Black Rot, which, so to speak, burnt up the shoots, leaves, and fruit; but the cordon turned towards the south, on which no signs of disease could be perceived in ordinary years, nearly a quarter of the yield of Grapes was entirely destroyed. We now come to the third cordon, which was

in the production of the disease, and that it shows the possibility of opposing the propagation of the pest by attacking the spores before they have had the time to produce their mycelium on the epidermis of the tender shoot." Up to the present time, in order to guard against the attacks of the Black Rot, we have only taken the necessary precautions at the moment when the disease has made its first appearance—in other words, when it has been too late; but from what we now know it is very evident that we must be on our guard before—at any rate at the exact moment when the spores of this cryptogam are beginning to be disseminated.

Fig. 3.—Young Grapes suffering from Black Rot.

It is not difficult to recognise the Black Rot in the malady which the Italian authors on diseases of the Vine describe as the "male nero" (the black disease), and the "male della bustula nero" (the disease of the black spot), which committed such havoc in certain of the Vineyards of the Italian peninsula in the year 1877. Most of the German authors on this subject, Herr H. Goethe amongst others, speak of this disorder under the name of "schwarzen brenner," or literally the black burner.

This disease is prevalent not only in nearly all the Vineyards of Europe and probably in all those of the ancient continent, but it seems to have attacked those of the New World, where it is known as the Black Rot. M. Planchon, it should be stated, was one of the first to point out the identity of the European anthracosis with the Black Rot of America. There is another form of this disease which the Americans call the Grey Rot—a form of the malady which is at present unknown in Europe, but which seems to have caused more damage to American Vineyards even than its swarthy congener, as we know it in Europe; but, unlike the last-named disease, it only attacks the Grape after it has entered on the period of maturity—in other words, it seems to take up its work as soon as the Grape is no longer susceptible to the attacks of the Black Rot. The first traces of the Grey Rot is a small brown spot surmounted by a globule. This spot enlarges and spreads, and soon destroys the whole of the Grape—both pulp and seeds—by rotting it, and not by drying it up, as in the case of the Black Rot. The Vines attacked by the Grey Rot have outwardly no signs of weakness or disease, but they are suddenly attacked by this pest while they appear to be in the plenitude of their vigour, and that with such violence that the most promising Vineyards are totally destroyed in a few days. The Grey Rot generally makes its appearance after a succession of warm or damp weather, and ceases when these conditions become altered.

It is an interesting question as to whether the Grey Rot is a particular form of the Black Rot, or whether it is a special disease *per se*. This is a problem which can hardly be decided at present, for the Grey Rot does not seem as yet to have made its appearance in French Vineyards. M. Meissner, of St. Louis, Missouri, to whom we are indebted for the above particulars concerning the Grey Rot, states that having visited in September last the Vineyards of the Charentes, the Bordelais, Provence, Languedoc, the Côtes du Rhône, and du Beaujolais, he could perceive nothing throughout the whole of those districts which in any way resembled the Grey Rot of America, and he seems to think that, luckily for us, the French climate is not favourable to the development of this cryptogamic disease.

We insist upon these details because it is not true, as some of the detractors of the American Vines persist in repeating, that they have been the means of introducing into France this same disease of the Grey Rot which has committed such fearful ravages in the Transatlantic Vineyards. The Grey Rot appears to have been confounded with the Black Rot, the effects of which are perfectly distinct, inasmuch as the latter disorder attacks the whole of the Vine from the very earliest stages of its growth, while the ravages of the former are confined to the Grape which has reached or passed the ripening stage. The French Vine has already had quite enough to undergo from Oidium, Phylloxera, and anthracosis without its being accused of suffering from a disorder which, unlike those storms of which we have lately been the victims, appears to be as yet confined to the American Continent.—"Revue Horticole."

Preserved Rhubarb.—Persons who have a taste for Rhubarb or Pieplant are reminded by "The Western Rural" that the stalks may be pared, cut in pieces an inch long, and dried the same as Apples or Peaches, or stewed and canned like small fruits, thus affording an excellent relish out of season.

Fig. 1.—Portion of a Vine leaf attacked by the Black Rot.

Fig. 2.—Shoots of the Vine attacked by the same disease.

trained against a wall with an eastern aspect and protected at the top, but its yield was uninjured, and in no way suffered either in quantity or quality like that of preceding years.

M. Marès, whom we have already quoted, thinks that the mischief done by the Black Rot to the shoots, leaves, and fruit of the Vine is produced by unexpected changes of temperature, which coincide with the sudden appearance of rain, fog, or sunshine. The damage done, says M. Marès, has too much analogy with that produced by late white frosts for the cause not to be similar, and that the fungoid bodies found by several naturalists in the portions of the Vine injured by this disorder are not the primary cause of the evil in question, but nothing more than one of its consequences. An eminent cryptogamist, M. de Barry, a professor of the University of Strasburg, has lately made a discovery which seems to throw an entirely new light on this interesting question. M. de Barry has succeeded in inoculating the Vine with the Black Rot at will by means of the excessively small spores of this particular cryptogam—the *Sphaeloma ampelinum*. He collects these spores by means of a damped camel's-hair pencil, and places them with all the necessary precautions on the seed of a healthy Vine, and finds that after a few days the anthracotic spot begins to develop itself. "The experiment devised by M. de Barry," says M. Planchon, who has been good enough to communicate to us the article written by the learned Strasburg professor, "proves incontestably that it is produced by the cryptogam which has been named by this author *Sphaeloma ampelinum*. This discovery is of primary importance, because it gives an explanation of the reason for the necessity of the intervention of water, or at any rate of a certain amount of humidity

THE FLOWER GARDEN.

ROCK AND ALPINE PLANTS IN YORKSHIRE.

CHEIRANTHUS ALPINUS and *C. Marshalli* are now finely in flower, and have healthy foliage, while last spring we could scarcely grow them. Such little gems as *Cortusa Matthioli*, *Hutchinsia alpina*, *Arenaria cespitosa*, and *Veronica saxatilis* have continued a long time in bloom. *Erodium Reichardi* may not be a plant of the rarest description, but certainly it is one of the prettiest of rock plants; *E. Manescavi* is more straggling in habit, but an abundant bloomer. *Erinus hispanicus* is strong and well-bloomed, but *E. alpinus* was nearly lost during the winter, and that has been the case I find in several other gardens in this neighbourhood. *Genista prostrata* is growing and blooming well, the present humid weather seeming to suit it perfectly. *Papaver alpinum album* is a most graceful subject, and *Potentilla alpestris* is throwing out its prostrate bloom stems to an unusual distance, the tips becoming erect, and carrying beautifully-formed, soft, clear yellow flowers that last a long time in perfection. *Anemone sylvestris* has had a bad season, owing to the heavy rains which we have had, otherwise it would have done well. I never saw the dwarf *Phloxes* so good; even *P. Nelsoni*, which always before with me bloomed so indifferently, is now completely covered with flowers. Such quaint plants as the *Ajugas*, *Erigerons*, *Euphorbias*, and *Salvias* are perhaps more characteristic than pretty; still, there are many gayer plants that could be better spared if need be. *Delphinium nudicaule* stands out richly with its singular-coloured flowers of orange-scarlet and dark, spare foliage. *Arenaria balcanica* is a good plant; it has glaucous foliage and large white flowers, possessing great substance. *Antennaria hyperborea* is densely bloomed, and, owing to its ashy-coloured foliage and lumpy pale red flowers, it somewhat resembles a nearly-extinguished coal-fire. A small piece of *Dryas octopetala* is prettily in flower. *Iberis corniculata* is simply grand, masses of it being sheets of snowy whiteness. Irises of all kinds here are most sparing of bloom. *Myosotis rupicola* and *M. alpestris* are new members here, but so fine are they that they are sure to win more patronage. We cut our first bloom *Rose* outside (on south wall) on the 12th inst. *Linaria alpina* has come up strongly from seed which has been eighteen months in the ground. *Dicentra spectabilis* is very weak and poor. *Anthericum Liliastrium* (St. Bruno's Lily) in front of dwarf shrubs, in good bold clumps, looks most chaste. *Lewisia rediviva* (a small plant) is doing well here. *Aquilegias* have made rampant growth—4 ft.—and are well bloomed. The variegated-leaved *Veronica gentianoides* is most satisfactory, and, what is not usual with variegated species, it carries finer flowers than the type.

Woodville, Kirkstall.

JOHN WOOD.

MOSAICULTURE.

WHETHER the particular style of gardening known to the French as mosaiculture and to us as carpet gardening is in accordance with good taste or not we will not now stop to enquire; that the system exists and is fashionable is sufficient for our present purpose. In order to practise it in perfection the laws of form and colour must be studied. Amongst the most successful cultivators of the art in France is M. Comesse, and those who had the good fortune to visit

the gardens of the French International Exhibition held last year had ample opportunities of seeing numerous specimens of his work. In a late number of the "Revue Horticole" was published a bed of this kind, contributed by M. Comesse, which we reproduce below, along with the list of plants with which it is to be filled, their places in the figure being indicated by numbers: No. 1, a Palm; 2, a group of Begonias; 3, *Coleus niger*; 4, *Lobelia compacta*; 5, *Eupatorium aureum*; 6, *Alternanthera versicolor*; 7, *Alternanthera amabilis*; 8, *Alternanthera amena*; 9, *Sedum sexangulare spirale*; 10, *Crassula Cooperi*; 11, *Echeveria pachyphyllum*; 12, *Kleinia repens*; 13, *Crassula Bolusi*; 14, *Yucca quadricolor*; 15, *Mesembryanthemum cordifolium*; 16, *Echeveria glauca metallica elegans*; 17, *Antennaria tomentosa* or *Sedum glaucum repens*; 18, *Echeveria secunda glauca*; 19, *Alternanthera paronychioides*. These may, of course, be varied at will, either by a complete change of colour, and even of size, or the size and colour may be adhered to although the plants themselves may be changed.

C. W. Q.

A ROCK GARDEN IN KENT.

As a pendant to the interesting description of the far-famed Alpine garden of the Messrs. Backhouse, at York, I should like to give one of a garden in the other extremity of the island. I know, I am glad to say, that described by your correspondent, and I think it quite impossible to exaggerate its beauty or importance.

Anything more natural than the arrangement, or more varied than the plants cannot be imagined. Its accomplished owner has, of course, unusual facilities. He has, independently of any commercial interest in his plants, a real hearty love for them; is an excellent botanist, and, with his correspondents in all parts of the world, he can bring together the various treasures which he receives from them. The result of

Mosaic Bed. Designed by M. Comesse.

all this is an Alpine garden which, as far as I know, is unequalled for beauty and extent; and every lover of hardy plants who has seen it will ever regard the first time that he did so as a day to be indeed "marked with white chalk." The garden which I am about to notice is of a different character. It is that of an amateur; it does not equal in extent or variety that of Messrs. Backhouse, yet, as an example of tasteful arrangement and successful culture, it is one well worthy of notice, and amply repays the visitor who may be induced to go there.

St. Alban's Court, the residence of Mr. W. O. Hammond, is situated about three miles from the Adisham station of the London, Chatham, and Dover Railway, close to the village of Nonington, and about nine miles from Canterbury and Dover, and is one of a cluster of gentlemen's seats which combine to make that nook of Kent very lovely. It closely adjoins Fredville, the seat of Mr. Plumtre, and Goodneston Park, that of Sir Brook Bridges—parks which are noted for their fine timber, especially Oaks, the Fredville Oak being entirely new—indeed, barely finished—and is one of the very best examples of Tudor architecture. The admirable taste of its owner has led him to keep free of all absurdities, such as are too often found in modern copies of those days, and every portion of it has been the result of careful study and personal superintendence. It is somewhat elevated, the terraces are now being finished, and will quite correspond with the building. They lead down to a well-kept lawn, in which is a parterre, on which the eye will rest with pleasure, the walled-in garden and shrubberies being out of

sight on the left; but the fine wood of the park shows well from the house and terraces. At the back of the shrubberies, and close to the garden, was a deep pit in which shrubs would not thrive, and so, by a happy thought, the owner determined to convert it into a rock garden. But there were no rocks in the neighbourhood, and so here is another instance, like that at York, where all the necessities for forming the garden had to be brought from a distance—in this case, I believe, from Tunbridge Wells, some thirty or thirty miles off. The garden is in the form of a semicircle; the rocks gradually rise from the bottom around the sides of the amphitheatre, which I should imagine, although I did not measure it, would rise up some 20 ft., and is some 30 yards or 40 yards across, giving ample space, as may be supposed, for a large variety of plants, which are carefully planted according to their several wants. At the period of my visit (June 4) some of the earlier spring flowers were over, and some of the later ones were not in flower; but there were many of great interest. *Gentiana verna* was one, and had evidently been flowering well in different parts of the rockery and had established itself completely. *Lychnis Gascasae*, with its deep rosy coloured flowers, and *Lithospermum Gastoni*, of an intense blue; *Potentilla rupestris*, with white flowers; *Arenaria purpurascens*, with its purple flowers, were in good condition; *Silene acaulis* had established itself most completely, and its dense cushions of bright green were a picture in themselves, recalling my first sight of them on the Col du Balme, in Switzerland. *Ranondia pyrenaica* was just coming into bloom, but a sad calamity had occurred in connection with this lovely plant. There was, when I saw the garden last year, a very large number of it in various parts of the rockery, but during last winter the mice attacked it, first carrying away the leaves and then eating the roots themselves. The place it especially delights in is a narrow fissure between two rocks, where it receives no sun, but where its broad, leathery leaves close to the surface of the rock, and its lovely mauve coloured flowers throw themselves up in great profusion. This colour is, I think, unique in herbaceous plants.

Of the *Androsaces*, *A. carnea* was over, and *A. lanuginosa* just coming into bloom, but *A. villosa* was especially beautiful with its soft silky foliage and white flowers with yellow eye. The white *Ranunculus amplexicaulis* and the pale sulphur *Meconopsis nepalensis* were flourishing, while *Mazus Pumilio* was forming a dense carpet, from which its pale violet flowers will come up in great profusion. There was a large variety of the *Saxifragas*, *Sedums*, and *Sempervivums*; amongst them a variety of *acraeoidium*, with a good deal of red on the rosettes, was very good and robust. *Saxifraga coriophylla*, *longifolia* vera, *Burseriana*, and others were fine. *Daphne Cneorum*, *Linaria prostrata*, *Primula Monroi*, *Astragalus monspessulanus*, *Sisyrinchium aneas*, *Anemone narcissiflora*, are doing well; but, in general, Mr. Hammond has not been successful with *Primulas* nor with his bog plants, although he has made an artificial bog, which it would seem ought to grow them; but the *Pinguiculas* were not thriving and the *Droseras* had perished. *Cypripedium spectabile* was growing very strong, and some of our British Orchids were also doing well. The lovely little *Myosotis rupicola*, with its intense bright blue flowers nestling down on its dwarf foliage, was so beautiful that it may well console growers of herbaceous plants for the impossibility of growing the lovely little *Eritrichium natum* in the garden. This latter is one of those difficult plants over which a grower never breaks his heart. Mr. Backhouse told me some years ago that he had spent £100 in trying to introduce it, but had failed. Mr. Elwes also informed me that he had tried it and sent some fine plants to Mr. Atkins, of Painswick; he had himself lost it after one season, and Mr. Atkins had managed to keep it alive for two, and then it had died; while Mr. Hammond had equally to record its failure with him. The lovely *Iberis juconada* was in good condition, but Mr. Hammond has the same fault to find with it that I have noticed—that so many of the plants lose their leaves and then seem to perish. However, it seeds so readily, and the seeds germinate so freely, that it is very easy to replace the plants when they become shabby. Various kinds of *Lilies* were doing well, and promised for a fine bloom, the early flowering kinds being already expanded. *Omphalodes Lucilae* was also in excellent condition, and is certainly an extremely interesting plant, and one that should be included in every collection.

I have only indicated a few out of the many plants that are cultivated in this rock garden—a garden which is certainly calculated to stir up a love for Alpine flowers in those who visit it, and to encourage those growers who have already essayed their cultivation; although to those who, like myself, can only indulge in a very small affair, it makes one feel somewhat humble. However, we cannot go beyond our capabilities of space or pocket, and so must rest content. I think I may say for its owner that he will gladly welcome any one who, possessed with the same taste, would desire to see his garden.

DELTA.

A BUTTERPOT BOUQUET.

IN the Academy exhibition last year was a pretty flower picture showing the use that may be made of a Dutch butterpot. It was one of the many good flower pictures painted by Miss Mutrie, who is a bright exception to artists who take this line, and who, generally speaking, conspicuously fail. The finest flower picture I can call to mind if one by Mignon, in the gallery at Amsterdam. It is a group of huge *Pæonies*, *Roses*, and other large flowers confusedly heaped up in a vase. The charm of that picture is to be found in the fact that the painted flowers are like real flowers, and give delight to the beholder. The average of flower pictures are like bits cut out of wall papers much more than like living flowers, and give pain rather than pleasure to the eye that is accustomed to note the characteristics of the reality. Miss Mutrie's picture reminded me of that of Mignon, and both reminded me that I had in my museum a fine old Dutch butterpot of a hard slaty grey colour with an uncouth pattern of blue and white stars on each side. I brought it out, and I crammed it with *Tulips*, *Pæonies*, flowers of *Seakale*, sprays of *Berberis*, *Trumpet Lilies*, *Asparagus*, the leaves of purple *Beech*, and many more such things as might by some be accounted coarse, and in about ten minutes I had a truly gorgeous butterpot bouquet. For a week it stood on the sideboard and defied the critics. Then I cleared it out and filled it with flower spikes and leaves of scarlet *Chestnut*, purple and white *Lilac*, *Scarlet Thorn*, *Trumpet Lilies*, double *Tulips*, and smaller oddments, and again it carried on the defiant trade, and misanthropes who witnessed its splendour instantly loved each other and all mankind. I advise all and sundry who possess Dutch butterpots to bring them out while there are many showy subjects in flower, and there is perhaps a new delight in store for them. The spread of the huge bouquet should be 18 in. or 20 in. over, and the whole should be as rich and full as flowers and leaves can make it, with bits of light spray peeping out to tone it down and prevent suspicion of vulgarity. The white flowers of the *Seakale* are invaluable for the purpose if they are properly wedged in between fiery *Pæonies* and *Tulips*, and there is scarcely a flower in the garden but may be pressed into the service to assist in the composition.—S. H., in "Gardeners Magazine."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Orchis foliosa.—This handsome terrestrial Orchid is one of the finest of the hardy kinds which thrive in our climate. It grows from 1 ft. to 2 ft. or more in height, and produces long dense spikes of rosy-purple blossoms, spotted with a darker hue. It begins to flower about the middle of May, and continues in full beauty for a considerable time. In the outdoor garden it delights in moist sheltered nooks at the base of the rock garden, or in some similar place, and it should be planted in deep, light soil. It is also perfectly amenable to pot culture, for which, on account of its neat habit, it is peculiarly well adapted, and it associates charmingly with other subjects used for greenhouse decoration. For this purpose the plants should be grown in a cool, airy frame, potted in fibry loam enriched with decayed manure, and when about to flower removed to the greenhouse, where for several weeks they will be a source of great attraction. It is also an effective exhibition plant, and, when well grown, such as we saw it a few days ago in Mr. Williams' nursery, at Holloway, it is scarcely inferior to some of its more showy epiphytic congeners from the Tropics. It is a native of Madeira, and has been introduced for some considerable time.—W. G.

Cypripedium Calceolus and C. spectabile.—We grow these here in large quantities in borders, where a little shade can be had. I used to adopt the water system with bad effects, but since I made a lucky find my compost has simply been peat mixed with small limestone shingle. In this the growth is astonishing, and some of the clumps of *C. Calceolus* bear some fifty blooms, all two on a spike, while *spectabile* nearly grows to 3 ft., often with three blooms. It is not generally known that *C. Calceolus* grows wild on the estate here, and not 100 miles from Kendal. I say wild, as it is spread over some considerable extent, and in two places. For many years past I have made it a practice on a particular day to have all the flowers pulled off, so that it may escape the notice of plant collectors, who swarm in this neighbourhood, and whose finding of any rare plant or species surely leads to its extermination.—R. CRAIG, *Levens Hall, Mithlthorpe*, in "Gardeners Chronicle." [Mr. Craig, we fear, tells too much.]

New Plant Disease.—M. Max Cornu has detected a new malady which attacks plants of the Order *Rubiaceae* grown in hot-houses. It appears that an *Anguilula* deposits its eggs in the roots, these swell and decay, the plant perishing rapidly. Precipitate sulphur has been recommended as an effective remedy.—"Athenæum."

The Wild Bluebell (*Scilla nutans*).—I was glad to see this charming native plant favourably noticed in *THE GARDEN* (p. 47), and have in some measure been anticipated in the remarks I had intended to make in reference to it. The "shade-loving Hyacinth," as I have heard it described, is at this moment the glory of our northern woods, and in one open plantation close to where I am writing may be seen perhaps twenty acres literally blue with it. It is seen to most advantage growing amongst Bracken (*Pteris aquilina*); the latter, where not too rank, with its feathery green, adds a charm to the otherwise monotonous acres of blue. White and flesh colours may also be found by those who choose to seek for them. No shade is too great for this plant. It will grow under the densest masses of Holly, and even under the Beech right up to the bole. The Spanish Squill (*S. campanulata*) is, as regards size, superior to the common *S. nutans*, and may be as easily naturalised. Some of the forms of *S. campanulata* are little inferior to the cultivated or Dutch Hyacinth, and far handsomer than what is known as the Roman Hyacinth (*Scilla romana*). Modern botanists have given our native Bluebell the name of "Endymion;" the old name of "non-scriptus" seems to be discarded. One of the family—a gem—*Scilla amethystina*, is now very pretty with me on rockwork.—THOS. WILLIAMS, Ormskirck.

A Little Sketch at Longleat.—The accompanying illustration shows the effect of certain very common native plants in landscape gardening. It is a little sketch, by Mr. Alfred Parsons,

Giant Burdock and Double Furze on margin of water at Longleat.

of a water margin at Longleat, where the giant Burdock is associated with double Furze—an odd combination, which struck us as very beautiful when the Furze was in flower. It is another proof, if one were wanted, of what good effects may be obtained in gardens by the use of the simplest materials.

Aerides Schroederi and other Orchids.—A fine example of this rare Orchid is now in flower in Mr. Philbrick's collection, in the Avenue Road, Regent's Park. It somewhat resembles the better known *A. maculosum*, but is much superior, as the blossoms are larger and the colours more clearly defined. The Cattleya house in the same garden is now also very gay with a choice assortment of the finest kinds, among which the several varieties of *C. Mossie* are very attractive; also the shy-flowering *C. lobata*, a lovely species. *Cypripedium Stonei*, *Epidendrum vitellinum majus*, and the various beautiful forms of *Odontoglossum citreum*, one of the best of cool house Orchids are likewise finely in bloom. On *Sobralia macrantha* we noticed several expanded blossoms, gorgeous, though fugitive. Among the Masdevallias was the curious *M. Peristeria*, the strongly-coloured blossoms of which have a purple oscillating lip, which, with the other parts, resembles a bird in miniature.

Iberis gibraltarrica.—This has again proved itself quite hardy, having passed through the severe winter with very little loss at Didsbury. We have a large quantity of it planted out on rockwork and on sheltered borders, and it is by far the most beautiful of the herbaceous Candytufts. It is readily increased by cuttings, and two lots of these have withstood the frosts with no other protection than that of a cloche. *Iberis* superba flowers a fortnight earlier than *I. corneifolia*, and is different also in its leaf, which is longer and narrower. After being some time in flower it becomes very pink, which mars its

effect when massed. *I. corneifolia* has not this fault, and, of the two, is the finer plant. A large mass of it is exceedingly beautiful, and it continues a long time in flower.—BROCKHURST.

Tender Annuals and Slugs.—In the planting out of all kinds of tender annuals, the greatest possible difficulty is experienced in saving them from slugs this year. Never before have these pests been so abundant. In the evening the soil is literally covered with them, and they fasten upon tender plants by dozens, and sweep them off wholesale in a single night. In putting out such tender plants as Balsams, Asters, Marigolds, Stocks, &c., fresh from the frame, the most disheartening results follow, as, in spite of all precautions, they require to be replaced again and again. Lime as we may (and nothing is more efficacious than dustings of fresh-slacked lime and new soot early in the evening, just as the slugs are first out for their night's meal), these dressings are constantly neutralised by the regular heavy rains which we are now experiencing, and thus the work of keeping the slugs in check becomes one of enormous difficulty. The hard winter, so far from killing such pests, doubtless had the effect of sending them deeper into the earth out of harm's way, whilst the long continued moist weather we have had enables them to breed by myriads long after the time when hot dry weather has generally sent them deeper into the soil in search of moisture. I find that slugs avoid *Lobelias*, *Nasturtiums*, *Antirrhinums*, *Pentstemons*, and a few other plants that have a strong astringent taste. It is a good plan, as tending to harden the plants before the final planting, to get them out of the seed-bed, and lay them in in rows for a week or so; they are then less succulent and less liked by the slugs.—A. D.

Violas and Pansies.—It would be well if some acknowledged authority would lay down a rule defining exactly what is a *Viola*. At the late Manchester Show Mr. Hooper's prize lot contained several Pansies classed as *Violas*. I understand that Mr. Hooper considers that there is no rule, but if we are to have prizes for *Violas* the judges should certainly disqualify exhibits containing Pansies. The only marked difference which could be insisted upon as marking the *Viola* is, I consider, the eye. A true *Viola* should have a small clear eye; anything with strongly marked lines diverging from the yellow centre becomes a *Pansy*. *Violas* are coming more and more into use for bedding purposes, and I believe that next year will bring some very choice sorts before us, so we ought to have the point clearly defined.—BROCKHURST.

—Last summer I endeavoured to point out the pedigree of both Pansies and *Violas*, tracing the latter to *cornuta* and *lutea*. *Enchantress* and *Perfection* still point to *cornuta* and *lutea*, and *Golden Gem* to our native *lutea*, but such *Violas* as *Chieftain*, *Tory*, and *Holyrood* are Pansies to all intents and purposes, having evidently been bred from the cultivated *Pansy V. tricolor*. Can any of the readers of *THE GARDEN* help us in this matter? Correctly speaking, they are all *Violas*, and it may be pointed out that the so-called *Violas* are continuous bloomers, but as to distinction, as regards exhibition, a *Pansy* may become a *Viola* and a *Viola* a *Pansy*.—T. WILLIAMS.

The Woodruff (*Asperula odorata*).—This is largely used in Germany for flavouring summer drinks. "Mai-Wein" is easily concocted, and furnishes a most delicious beverage at garden parties. Take a handful of Woodruff flowers, cut off short, put them in a bowl, sprinkle them with two table-spoonfuls of white powdered sugar; pour over them a bottle of light hock and leave it for ten minutes; then pour off the wine, carefully straining out the leaves, and let it stand till required, in ice if practicable; then add, if wanted light, two bottles of soda water, or if wanted very good, one bottle of sweet champagne and one bottle of soda water.—BROCKHURST.

Narcissus Bulbocodium.—I am happy to report the perfect success which has rewarded me in raising this charming *Daffodil* from seed. Imported bulbs I have found to flower well in the open border the first year, but after that they generally disappear, or at least never flower again. Three years ago I planted out a box of seedlings, which flowered freely in the spring of 1878, and, having stood last winter without protection, have again flowered this spring. I am well pleased at this result, for the Hoop-petticoat *Daffodil* is one of the choicest of its kind. *Narcissus juncifolius* is a distinct late flowering kind that is worth having.—SALMONICRIS.

Wintering Gladioli Out-of-doors.—Bulbs of these left in the ground through the winter are now shooting up strongly. They were only protected by a mulching of half-decayed leaves about 2 in. in thickness, some of them being delicate kinds. The soil is light, sharp loam, naturally drained. Other kinds, such as *Gladiolus*, sharp loam, and to which no mulching was given, are growing equally well, facts which, after such a long trying winter and late spring, surely speak much in favour of Gladioli being harder than most people give them credit for.—W. DIVERS, Winton, near Maidstone.

HEATING BY HOT WATER.

THE scientific principles on which the action of a hot-water apparatus depends are now so perfectly ascertained, and permit of such easy adaptation to every kind of circumstance, that no one need be deterred by any fear of disappointment from adopting this system of warming. More than one-half of the hot-water pipes manufactured in Great Britain are used in the warming of horticultural buildings. In fig. 1, A represents the boiler, and B C D a line of pipe. So long as the fire is out, and the water in the whole apparatus equally cold throughout, there is no motion, because the column of water in C counterbalances that in A. And the same state of rest would obtain after the fire was lighted if the water in every part could be maintained at the same temperature, and consequently at the same specific gravity. But that is impossible, inasmuch as the material of which the pipes consists abstracts the heat from the water, and parts with it to the surrounding air. Heat makes water expand, and diminishes its weight in a corresponding degree; iron pipes cool hot water flowing through them, and increase the weight of their fluid contents accordingly; the result is, that the column C is always heavier, bulk for bulk, than the column A. This causes a constant circulation of the water in the direction of the arrows, its rate being proportional to the difference of temperature between C and A. There are two systems of heating by hot-water—the high pressure and the low pressure systems. In the former the apparatus and pipes are hermetically sealed, and the temperature rises to 350°, and sometimes higher; with the latter system there is always an open communication between the water and the atmosphere, so that the water cannot rise above 212° in the hottest part. The high pressure system, in virtue of the greater heat imparted to the pipes, allows of a much smaller pipe being used, but the heat is so considerable, and practically so much beyond control, to say nothing of the risk of an accident from explosion, that this method is by no means so suitable for horticultural work as the other.

Quantity of Pipe.

A square foot of glass will in one minute cool down to the temperature outside $1\frac{1}{2}$ cubic ft. of the air inside the house. It is evident, therefore, that as much heat as the glass walls and roof can pass away to the air outside in a minute is the quantity that must be supplied by the pipes in that time. The prevalence of high winds undoubtedly tends to an increased loss of heat, but the cooling effect of wind cannot be measured by its temperature; its velocity must also be considered. Wind travelling at the rate of 30 miles an hour cools the air of a glass house as rapidly as a still atmosphere registering 25° lower on the thermometer. The first thing to do, therefore, is to measure up the area of glass. If the frame is of wood deduct one-eighth from the total surface; but if of iron make no deduction, inasmuch as iron sash-bars allow of the escape of heat as readily as glass itself. The following table shows how many feet of 4-in. iron piping maintained at a temperature of 180°—the average temperature of a low pressure apparatus—will suffice to raise 1000 cubic ft. of air in a minute from the temperature obtaining outside to that required in the building:—

Actual or virtual temperature.	Temperature required inside.							
	45°	50°	55°	60°	65°	70°	75°	80°
10°	144	135	295	235	270	300	350	400
15°	135	155	180	212	245	285	325	375
20°	105	135	160	190	221	257	295	335
25°	85	110	137	165	196	225	260	310
30°	65	87	110	140	175	206	230	285
35°	45	65	90	120	148	185	215	260
40°	25	45	70	95	125	160	190	230
45°		25	45	72	100	130	165	200
50°			25	65	75	105	130	170

Now, for instance, it is desired to find out how much pipe will be required for a house, the glass area of which is 800 square ft., exclusive of wood sash-bars, that has to be maintained at a temperature of 60° when the lowest temperature outside is, allowing for the effect of winds, 10°. 800 square ft. of glass will cool 1000 cubic ft. of air from the temperature inside to that ruling outside, viz. 10°. In the table, on referring to the column headed 60°, and opposite 10°, is the number 235, which is the quantity of pipe, of 4 in. diameter, that will give off as much heat in a minute as the glass will waste. The size of the building, i.e., its cubical contents, does not affect the question; it is the glass alone which gives off any appreciable heat, and therefore whatever quantity of pipe will compensate for this loss of heat by the glass will also warm the house, in the first instance, and maintain it at the required temperature afterwards, because until the air is heated to its maximum the glass will cool proportionately less air, the cooling power of the glass being obviously exactly proportional to the difference between the external and internal temperatures. The pipe, therefore, gives off at first more heat than the glass wastes, until at last the point is reached when the two are

just balanced, and that balance is the temperature which is wanted in the house. The best size of pipe for general use is 4-in., but sometimes smaller are required for the sake of convenience. If 2-in. are used twice as much will be wanted as if 4-in. had been put down, and one-third more if 3-in. are used. Small pipes heat more rapidly than large ones, but they also cool much more rapidly. For connecting houses with each other, or with a boiler house in a central position, 2-in. pipes will suffice; they must, however, be placed in a trench filled with sawdust to prevent loss of heat.

The ventilation of horticultural buildings deserves very careful attention. Plants have two sources of food—the soil in which they grow and the air they breathe. Motion and consequent change exist in every climate, and cannot be entirely withheld from plant houses without a corresponding loss of vigour and compact growth. The advantages to vegetation of brisk motion in the air are, therefore, obvious. Suppose that an opening is made in a hothouse wall at the floor-level, and another in the opposite wall at the top; a current of air will enter at the bottom, and passing in a straight line to the top opening, escape thereat, the rate at which it travels being proportionate to the difference in temperature of the outside and inside atmospheres. To secure an even distribution of ventilating effect throughout the house, the ventilating inlets and exits must be set at regular distances, and the total area of the inlets should be more than that of the exits to prevent back-draught. In summer it is always more difficult to secure ventilation than in winter, because of the smaller difference between the two temperatures, that of the outer air, on the one hand, and that of the inside air on the other. It will be necessary, therefore, to take as a basis for calculation the temperatures obtaining in the hottest weather, and the ventilators must be sliding so that the opening can be contracted as may be necessary on the approach of colder weather. The inlets must always open upon, behind, or under the heating pipes, whether the latter are on the floor or in trenches covered with iron trellis-work. By this arrangement the air will be warmed as it enters the house.

The following table shows the quantity of air that travels through a pair of ventilators per minute, the area of each being 1 square foot:—

Height of exit above inlet in feet.	Excess of Inside Temperature over Outside.					
	10°	15°	20°	25°	30°	
15	200	245	280	320	350	
20	230	285	330	370	400	
25	260	320	370	410	450	
30	290	350	400	450	500	

For instance, if the exit ventilators are 20 ft. above the inlets, and each set of an aggregate area of 6 ft., there will be a volume of 1980 cubic feet of air passing through the house in a minute when the temperature of the latter is maintained at 20° over that of the air outside, and these 1980 cubic feet must be added to the quantity of air cooled per minute by the glass, walls, and roof in calculating the quantity of pipe required to warm the house when ventilated.

There are many ways of securing bottom-heat. Pipes (two of 4 in. diameter for a bed 6 ft. wide) surrounded with large stones are sometimes used for that purpose. Many use tanks for this purpose. These are made of 1½-in. deals, grooved and tongued, and

Fig. 1.—Section of Boiler and Pipe.

secured by ties of iron rod, the joints being made tight with white lead or of brickwork cemented inside, and covered with thin slates. A division is run along the centre to nearly the extreme end of the tank, so as to make the hot water flow its whole length before it returns. The flow and return pipes, instead of being only connected with the tank, as they would be in the case just mentioned, are sometimes carried right through it. Pipes carried up from the tank pass through the beds and give moisture to the air when required, and a tap fixed in the tank allows of the water to be drawn off at will.

The ordinary plan of moistening the air is by means of troughs and shallow pans, preferably made loose and of tinned sheet iron, with a shallow bottom to fit the curvature of the pipe. The best position for evaporating pans is in the direct line of the ventilating inlet, many cultivators making their houses too hot and too moist. It is quite true that heat expedites the growth of a plant, and that moisture is essential to its existence, but heat and moisture are not everything. A sufficient temperature during the day, and as much humidity as will suffice to prevent any chance of the natural moisture of the plant being dried out of it, coupled with a plentiful supply of air, make the balance of maturing agencies to be aimed at, and at night plants require rest. To stimulate them then by keeping the house unnecessarily warm results in weak growth.

Boilers.

Taking everything into consideration, there is no pattern boiler which presents so many advantages as the saddle. Large numbers of boilers requiring no brickwork setting are now sold, and one variety of these—the upright—allows the fire to be easily banked up for the night without necessitating a boiler unnecessarily large. A perfect boiler is one that presents a maximum surface to the direct action of the fire, possesses a large and free way way, and has as few angles as possible. Wrought-iron boilers must more readily than cast-iron ones, but they are much less liable to be cracked by careless stoking. Water can absorb heat from an iron plate two and a-half times as fast as the iron plate can receive it from the fire. This being the case, it is very evident that a boiler of any given length or size will have its heating power considerably increased if

Fig. 2.—Horizontal Section of Boiler.

currents from the top one. K k are two fire brick lumps with an opening between them of about 4 in. (more or less according to the size of the boiler). When the boiler is made with a terminal end or with a watery check-draft, both or only one of these lumps is dispensed with. Fixed as shown, they exert a reverberatory effect. When the boiler is more than 6 ft. long, the bottom lump is omitted and one L fixed inside the boiler, leaving a space of about 6 in. in depth between its top and the boiler crown. The side flues M m are 4½ in. wide and the full depth of the boiler. The arrows indicate the direction of the draught. Every square inch of boiler surface is thus used to the best effect. N is a damper fixed in the chimney at a convenient height.

Coke and coal in equal proportions, or coke and spent tan make excellent fuels. The perfect combustion of fuel is a point of the greatest importance. It can be effected only by the supply of the necessary amount of oxygen, at the temperature of the furnace fire, to the place of combustion. There are three methods of doing this,

none perfectly successful in all cases, but either better than nothing. First—a judicious use of the dead plate with a ventilator in the fire door. Each fresh charge of fuel is placed on to the dead plate and there baked or coked. The more volatile constituents, accompanied by a quota of air passing through the ventilator in the furnace door, pass on to the scene of combustion, and, attaining the proper temperature, burst into flame before they reach the flues, whereas if the fuel had been thrown direct on the fire, or if the supply of air through the fire door had been allowed to reach the place of combustion at too low a temperature, the volatile gases of the fuel would have escaped as dark smoke, or as colourless and half-burnt carbon (carbonic oxide) into the flues.

Another plan is to lay pipes in the flues, so as to receive air from the outside and deliver it behind the bridge. Provided that the supply be sufficient in quantity, and the position of the pipes in the flues such that the air passing through them is raised to the proper temperature, there is not much chance of any unburnt gas getting into the chimney. A third plan is to carry an iron pipe along the inside crown of the boiler, one end screwed into the boiler and the other terminating in a rose or spreader. The pipe, being small, carries only as much water as the heat of the fire suffices to burn into steam. This is expelled with considerable force

Fig. 3.—Vertical Section of Boiler.

among the highly-heated gases, and, in virtue of the oxygen it contains, expedites combustion. For a small apparatus, gas or petroleum can be used—of course, not without a flue to carry off the products of combustion. None but clean water should be used with a hot-water apparatus, and, when possible, soft in preference to hard. Where the former cannot be had, the addition of sal-ammoniac in powder prevents the deposition of the salts of lime held in solution by the water. The supply cistern is to be fixed with its bottom not lower than the highest part of the apparatus. In size it should be capable of holding one-thirtieth of the whole water-contents of the boiler and pipes, this being the quantity which will return to it when the whole liquid mass is expanded by heat. A hundred feet of 4-in. pipe contain 54½ gallons.

Joints and Air-pipes.

The old-fashioned iron-rust cement is falling into disuse. It is undoubtedly very strong—in fact, unnecessarily so except for the boiler-socket joints. The socket, after receiving the spigot pipe, is first caulked with loosely-spun yarn, and the cement, made of 10 lb. of sifted iron borings with 2 oz. of sal-ammoniac in powder, and moistened with water, carefully driven in till the socket is full. The iron cement is now advantageously replaced by one of red and white lead. Joints made with india-rubber are very convenient. They

Fig. 2 is a plan at the line a b on fig. 3, which is a side elevation. After building up the foundation to the proper height, the bars A, supported on two bearers, are placed flush with the face of the boiler B, and with their upper surface on a level with the bottom of the boiler. The remainder of the furnace bottom C is made up of brickwork. In front of the bars and on the same level is fixed the dead plate D, a plain iron plate, 9 in. wide, and in length equal to the width of the boiler. In front of the dead plate comes the fire door E, and beneath it the ashpit door F. G C are short pipes with flange covers communicating with the boiler for the purpose of cleaning it out. To one of the covers can be attached a draw-off tap for emptying the apparatus of water. H H H are three flue doors, one for cleaning out the top flues, and one for each of the side flues. I is a ridge of brickwork supporting the arch; J, a stout cast-iron web, one at each side, supported by being built into the side-work, to divide the side

That is, counting 3 ft. of flue surface as equal to only 1 of fire surface.

are easily fixed, allow of additions or removal with a minimum of trouble, and provide for the expansion and contraction of a length of pipe as the heat rises and falls. This expansion is small, but irresistible. Where cement joints are used, short pieces of round iron, placed under the pipes, allow them to expand and contract without any chance of danger from fracture. Wherever, as at dips and returns, air is likely to collect in a system of pipes, taps or pipes must be fixed to permit of its escape. The latter, carried up above the water-level, are the best because they require no attention. The flow pipe or pipes should always be taken, as far as practicable, directly to the highest level of the circulation. For, if two circulations, at different levels, are worked from the same boiler, the one at the higher level is apt to monopolise the supply of hot water. When, however, the two levels branch off from one upright pipe, the introduction of a knee just above the lower branch will secure something like a fair division of hot water. The distance between the horizontal flow and return pipe at their points of junction with the boiler should be 12 in. at least. This will secure a good circulation with a long length of pipe, but where there are dips the depth of these must be added to the 12 in., or the circulation of the water will be very slow. A small frame contiguous to the house can be warmed by a boiler fixed at the back of an ordinary sitting-room fire-grate. In fact, such are the capabilities of the system of heating by hot water, and so easily does it adapt itself to a variety of circumstances, that there are, doubtless, nooks and corners around or about the majority of houses which could, by a moderate outlay on the part of a judicious cultivator, be made to produce, *pro rata*, results equal to those obtained from extensive hot-houses.

CHAS. S. WOODROFFE.

NOTES OF THE WEEK.

Eremurus robustus.—M. A. Lavallée, the President of the Central Horticultural Society of France, has very kindly sent us specimens of this giant herbaceous plant, which is a native of Turkestan. It was sent to him three years ago by a Russian friend, and M. Lavallée believes it to have been the first time the plant has flowered in France. The flower-spike he sends us is a huge one, measuring considerably more than 7 ft. in height. He has two other stems larger still, measuring not less than 10 ft. in height. It flowers somewhat after the fashion of the old white Asphodel, the blossoms being of a transparent white colour, with green stripes outside, and bold orange stamens, the colour of which is seen through the buds before they open. The plant is perfectly hardy, and though liking deep loamy soil, does very well in a sandy one. We are very glad to notice that M. Lavallée, who has hitherto done so much for trees and shrubs, is now adding to our treasures of hardy herbaceous plants.

New Pelargoniums.—The nurseries of Messrs. F. & A. Smith at West Dulwich are now well worth a visit in order to see the Pelargoniums alone, which are, of course, as they have been for a long time, the leading feature in Messrs. Smith's establishment. The novelties that have been sent out within the past few years from this nursery are characterised by their early and free-flowering properties, combined with fine form and rich variety in colour. Their habit, too, is dwarf and sturdy. The new kinds to be sent out during the present year are very fine indeed, and show a marked advance on older sorts.

Ageratum Cannell's Dwarf.—Amongst the numerous novelties to be seen at Mr. Cannell's nursery, Swanley, few attract more attention than this exquisite little bedding plant, which is unquestionably the most desirable of its class yet brought out. It does not exceed 6 in. in height, and assumes a broad, flat head profusely studded with large clusters of bright lavender-coloured flowers. For bedding purposes, especially for carpet bedding, it is a decided acquisition, and has the additional property of producing a continuous succession of flowers till late in the autumn.

Iris Telfordii.—Under this name Mr. Osborn sends us a superb, large and fragrant Iris, resembling at first sight the German Iris, but much larger, and with a well-marked though delicate odour. It is a valuable plant, which should not be lost sight of by all who are interested in the bolder kinds of hardy flowers. The Fulham Nurseries in old times ranked amongst the most famous for hardy plants, and we are pleased to notice that the present Mr. Osborn does not intend to let their interest in that way diminish.

Agapanthus umbellatus candidus.—This is a desirable variety of an old favourite, and quite an acquisition, its large umbels of pure white blossoms being very effective, especially when grouped with other plants in a greenhouse. Thus situated, we saw it a few days ago in Mr. Bull's nursery at Chelsea.

Asparagus plumosus.—We lately saw some fine examples of this elegant Cape climbing plant in Messrs. F. and A. Smith's nursery at West Dulwich, and we were much struck with its light, graceful appearance. Its stems are slender and twining in habit, and the small, needle-like leaves are produced on slender twigs, which form a flat expansion of triangular outline. For training up the rafters of a greenhouse, or even for pot culture, this *Asparagus* is an invaluable decorative plant, and one that is likely to prove useful for cutting purposes.

Pelargonium Freak of Nature.—Of the host of Pelargoniums with variegated foliage, perhaps none presents a more singular appearance than this Freak of Nature, specimens of which we saw in Mr. Cannell's collection at Swanley. In general aspect it somewhat resembles the variety *Happy Thought*, but is less robust and more compact in growth. The leaves are almost entirely creamy-white, with a much crimped edging of bright green. Altogether, it at once reminds one of some of the sports of Scotch Kale.

A Striped Forget-me-not.—The list of varieties of cultivated Forget-me-nots is by no means numerous, and the addition to it of a pretty novelty that Mr. Cannell showed us the other day is a welcome acquisition. Its flowers, which are of moderate size, have a ground colour nearly white, with five stripes of blue radiating from the centre in a star-like manner, producing a pretty as well as quaint appearance. At present we are unable to speak of its habit, or whether it exists in quantity or merely as a solitary sport.

The Pelargonium Society.—We are requested to remind the members that, although the Society's show has been postponed from June 24 to July 8 in consequence of the lateness of the season, it has been arranged that the censors and executive committee should meet on the former as well as on the latter day for the purpose of awarding the Society's certificate of merit to deserving novelties in all the classes of the Pelargonium, so as to ensure them being adjudicated upon in their best condition.

Genista prostrata.—This is one of the showiest Genistas with which we are acquainted, and one which makes a capital plant for overhanging ledges in the rockery, where for several weeks it quite enlivens its surroundings by means of its bright yellow flowers. Another desirable method of growing it is grafting it on some of the erect-growing kinds, of which we saw some specimens in Messrs. Smith's nurseries at Dulwich, where they formed some of the most attractive of spring-flowering shrubs.

Irises.—We have received from Mr. Joseph Stevens a beautiful and varied group of Irises from his richly-stored garden of hardy plants at Byfleet. Nothing can better illustrate the slight use that people make of the great wealth of flowers at their disposal than these same Irises. One sees almost everywhere the old purple German Iris. The fact that there are scores of equally beautiful and yet distinct kinds which can be all easily grown in any soil in the town and in the country does not seem to be taken advantage of in gardens generally.

Geranium armenum.—By far the finest specimens with which we have yet met of this beautiful hardy plant we saw the other day in Mr. P. Rooke's garden at Weybridge, some of which were nearly 3 ft. through, and covered with handsome blossoms, which are from 1½ in. to 2 in. across, of a rich deep magenta with a central blotch of shining black, a colour with which the petals are also delicately pencilled. Considering that it is such an ornamental kind, it is not nearly so well known as it ought to be; indeed, it is seldom met with in collections. A coloured illustration of it will be found in *THE GARDEN* (Vol. XI., p. 478). In the same garden a fine mass of the lovely blue Columbine (*Aquilegia coerulea*) was very conspicuous, as was also a collection of hardy Ferns, rich in variety and grand specimens; in fact, these form the specialties of the garden.

New Hybrid Rhododendrons.—Many fine new hybrid Rhododendrons are in flower for the first time in the Lawson Nurseries, Edinburgh, and, along with the large collection of already well-known kinds now in full bloom, form a magnificent exhibition such as is rarely seen so far north. It was scarcely expected that after the late long-continued and most severe winter the flower-buds would have escaped, but, thanks to the ripening weather of last summer and autumn, the plants appear to have been matured for the emergency, and are blooming more freely and the trusses are finer than have been produced for several years. Two examples of the new hybrids have been submitted to us. One a pale yellow, very showy and distinct; this is a cross between Smith's Yellow and Russelianum. The cross was effected in 1868, and the produce is now flowering for the first time. The other hybrid referred to is one of a large batch of seedlings grown from Aucklandi and John Waterer hybridised in 1867, and has been

already well described as being "worthy of both parents." We are informed that this new and distinct strain will soon be sent out, and no doubt, from their great beauty and distinctness, will soon find their way into collections. Besides having sufficiently proved their hardiness, they will form magnificent conservatory plants for winter and early spring flowering.

Calochortus elegans var. **Tolmiei**.—A plant of this extremely rare variety is now in flower in the Kew collection. Though it is similar in some respects to the type, it is abundantly distinct, as it is considerably larger in all its parts, growing 1 ft. 15 in. high. The flowers are $1\frac{1}{2}$ in. across, of a pale lilac tint with the inner faces of the petals entirely covered with hairs. It is certainly a very desirable plant, and should be sought after by hardy plant lovers. It is found in the vicinity of the Wallamet River, in Western North America.

Gigantic Poppies.—Mr. Joseph Stevens has submitted to us cut blooms of *Papaver orientale* major from his garden at Byfleet. They are the largest we have yet seen, measuring between 8 in. and 9 in. in diameter, with a conspicuous blue-black blotch at the base of each petal and a large tassel-like tuft of stamens in the centre, which, combined with the brilliant scarlet hue of the petals, has a gorgeous effect in the garden, and is much enhanced when mixed with other subjects. It grows about 3 ft. high, and in good soil it quickly grows into specimens as much through. The fine variety is yet far from being common, but it is so much superior in all respects that it deserves to be better known, for there are no plants which tend to enliven the garden at this season as masses of these showy plants.

Fritillaria Hookeri.—A fine flowering specimen doubtfully referred to the above is now in flower at Kew. It much resembles, if it is not identical with *F. macrophylla* (Lilium Thomsonianum). It is about 2 ft. high, and bears nineteen flowers, which are rather large, and of a pale rose lilac. *F. Hookeri* inhabits the Lachong valley in Sikkim, where it grows at an elevation of 1000 ft. above sea level. It was discovered by Sir Joseph Hooker about thirty years ago.

Chrysanthemum frutescens.—We have received from a correspondent in Ireland a photograph of a remarkably fine specimen of this *Chrysanthemum*. It is said to measure 7 ft. 4 in. in height, and 18 ft. in circumference; and an accompanying note states that it was received in the shape of a rooted cutting only three years ago, thus showing a remarkable instance of rapid growth; it is also stated to have been a perfect mass of bloom for more than a month at the time when it was photographed. A plant of such a high decorative character certainly deserves to be more extensively grown than it is, both for adorning the greenhouse during spring and the outside borders in summer.

Xerophyllum asphodeloides.—We noticed flowering examples of this rare hardy plant a few days ago in Mr. G. F. Wilson's garden at Weybridge. It is tuberous-rooted, and has the aspect of an Asphodel, having dense tufts of Grass-like leaves, which are very tough in texture and rough at the edges, and which grow 1 ft. or more long. The flower stems, which are about 2 ft. high, are furnished with needle-like bracts, and terminated by a compact pyramidal raceme of snowy-white blossoms nearly $\frac{1}{2}$ in. across, borne on slender white stalks, from $1\frac{1}{2}$ in. to 2 in. long, which diverge horizontally from the stem. Such a showy and desirable plant deserves to be better known, more particularly as it is said to attain 4 ft. in height.

Habenanthus pratensis fulgens.—This brilliant plant which Mr. Nelson proved to be hardy in his garden is this year sending up eleven spikes. It will be remembered that we figured it in THE GARDEN some time ago, but no coloured figure could do justice to its extraordinary vividness and colour when seen in the garden. It is in all ways quite a distinct kind among hardy flowers, and we trust will be found equally free and hardy in other gardens as it has been at Aldborough, near Norwich.

Lilium lancifolium rubrum.—It may be interesting to know that this Lily is perfectly hardy, having stood out-of-doors three successive winters here and bloomed freely; plants of it are now nearly 2 ft. high. These are planted at the foot of a low south wall (about 3 ft. high), and are growing in a bed of Czar Violets, which form their only protection. Our soil is rather light in character.—W. DIVERS, *Winton, near Maidstone*.

Iris longipetala.—This, one of the handsomest of the beardless section of Irises, is now in great beauty in Mr. G. F. Wilson's garden at Weybridge. It has erect, sword-like leaves about $1\frac{1}{2}$ ft. high, and flowers some 4 in. across, with broad, ovate, drooping falls of a lavender tint, delicately feathered with lines of a darker hue. The standards, which are rather narrow, are plain, and of a deep lilac

colour. It is a native of California, and is still one of the rarest in collections.—B.

NOTES ON HARDY PLANTS IN FLOWER.

Byfleet.—A stroll through such a garden as that of Mr. J. Stevens, at Byfleet, in which hardy plants are made a speciality, is indeed a treat, even to those who are not particularly conversant with plants. It contains between six and seven thousand species and varieties, and of course a large number of duplicates; it differs throughout the whole year it is a continuous source of interest, but it is more especially so during the summer months. At present it is gay with choice varieties of *Rhododendrons*; also with many forms of that beautiful Chinese shrub *Weigela rosea*, and Irises in endless variety, among which the beautiful *I. Victorine*, figured in THE GARDEN (Vol. XIII., p. 80), was conspicuous. The most noteworthy of the rarer plants in flower were *Lithospermum Gastoni*, a beautiful Pyrenean Borage-wort, with which many experience some difficulty in getting it established; here, however, it is evidently thriving admirably and producing multitudes of sky-blue blossoms. Another lovely plant of the same family is the mountain *Cynoglossum* (*C. montanum*), which bears terminal clusters of blossoms similar in form and colour to those of the Italian *Anchusa* (*A. italica*). We also noticed here *Anthericum* (*Chrysobactron*) *Hookeri*, a New Zealand Lilywort of rare beauty, delighting in boggy situations, and now producing its pretty orange-coloured flowers very freely in loose racemes. Scouler's *Pentstemon* (*P. Scouleri*) has proved itself to be perfectly hardy, having withstood the past winter and being now covered with handsome large lavender-tinted flowers. The Altaian *Dracocephalum* (*D. altaicum*) is a plant not often met with, though it is one to be recommended. It has a spreading, prostrate habit, its branches being covered for nearly their whole lengths with deep purple blossoms of considerable size, which are very showy. The Round-leaved *Ononis* (*O. rotundifolia*) is another beautiful plant, of shrubby, compact habit, from 1 ft. to 2 ft. high, and at the present time covered with pretty rosy blossoms. The white-flowered *Dielytra spectabilis* we found here growing stronger than we have hitherto seen it, and a charming plant it is, the pure white flowers contrasting admirably with the deep green foliage. On the rockery were numerous Saxifrages, including the elegant *S. lanatosus*, which is equaled by few and surpassed by none. *S. Mawiana* and *Wallacei* were also flowering freely, and here was also the pretty Canadian *Cornel* (*Cornus canadensis*), with its white flowers surrounded by a collar-like whorl of leaves. A fine tuft of *Saponaria ocyroides* was highly attractive, and is certainly one of the showiest rock plants we have, hanging as it does so gracefully over the rocks, and flowering with the utmost profusion. A plot devoted entirely to variegated shrubs and herbaceous plants was a source of much interest on account of its novel appearance. It shows at a glance what a large number of plants assume this character, and when in such number there is sufficient diversity to render the collection highly picturesque.—W. G.

Weybridge.—The garden at Heatherbank has long been famous for its Lilies, but though this beautiful family is always the foremost consideration with Mr. Wilson, the choicest of the Alpine and herbaceous plants also receive much attention, the collection of which bids fair to develop itself into an important department. The favourable position of the gardens is highly conducive to luxuriant growth, for here one may see them revelling almost in native vigour, and producing flowers in profusion. The Columbines thrive remarkably well in the lower garden, which is sheltered from northerly and easterly winds. Here are huge specimens of the beautiful Californian Columbine (*Aquilegia californica*) bearing scores of pretty scarlet blossoms, which contrast finely with the canary-coloured flowers of *A. chrysantha*. Though far from being showy, the green-flowered species (*A. viridiflora*) is noteworthy on account of its rarity. Its flowers are somewhat small and of a dull greenish hue. The Cashmere Larkspur (*Delphinium cashmirianum*) is also thriving here with equal vigour, and is a highly desirable species. *D. tricornis*, which grows about 1 ft. high, is an interesting novelty with deep purple blossoms. The Edelweiss (*Gnaphalium Leontopodium*), the characteristic Alpine of the Swiss mountains, has already produced its woolly bracts, and will shortly be in full flower. Another pretty Alpine is the Arctic Bramble (*Rubus arcticus*), which grows but a few inches high, and bears numerous pretty magenta-tinted blossoms. One of the best of the dwarf *Potentillas* is *P. antiqua*, a charming species from the Himalayas. It is trailing in habit, has deep green, three-toothed leaves, and flowers of a clear yellow of about the size of a shilling. *Primula capitata*, also from the same region, has few rivals amongst hardy Primroses; the deep rich purple blossoms, borne in dense clusters, dusted with a white

mealy substance, are very attractive. *P. sikkimensis*, too, is in fine condition, and has withstood the past winter with impunity. *Symphandra Wanneri* is a highly desirable plant, as it is dwarf in growth, and bears pretty purplish blossoms in profusion. The same remarks apply to *Campanula nobilis*, which we saw here in very fine condition. The Alpine Poppy, with flowers varying in colour from reddish-orange to pure white, is almost a troublesome weed, so quickly do the seedlings grow. Amongst Alpines of humbler growth we noticed the charming *Dianthus glacialis* and *alpinus*, both producing pretty rosy blossoms freely. *Ramondia pyrenaica* was represented by several plants in a most thriving condition, and thickly studded with delicate lavender-tinted blossoms. In the upper garden is the rootstock to which we have often had occasion to allude, and of which illustrations may be found in *THE GARDEN*. It is now gay with fine specimens of different varieties of *Azalea mollis*, one of which measured 4 ft. through, and was covered with large blossoms of a deep salmon tint. Near this was *Primula japonica* in grand masses, which is certainly the most desirable method of growing it, as the foliage greatly relieves the rigid habit of the flower-stem. Here also were large clumps of the pretty white-flowered *Arenaria grandiflora*, intermingled with the blue *Lithospermum prostratum*, and producing an effect which was very striking.—IV. G.

INTERNATIONAL HORTICULTURAL EXHIBITION FOR 1880.

THE Committee appointed to carry out this exhibition have rejected the resolutions carried unanimously by the large meeting of horticulturists held at the Royal Albert Hall on the 27th of May, 1879, a fact which shows that they are determined that a grand international show shall not be held in London next year. If they had been willing that a fair and open discussion should take place, why did they object to a more representative deputation from the large meeting which took place in the Royal Albert Hall? Why was it that a score or more of our best horticulturists were sent away and told they could not be admitted? Why should this Committee still wish to maintain a position so much out of character with the present times? and, after being asked to dissolve and give place to a Committee of Progress, to the progress of horticulture in this country? See what can be done in a city like Manchester, and under the guidance of one determined man; only 60,000 people visited the exhibition at Old Trafford in Whitweek, and there was a profit of £800. That 60,000 people could be induced to visit an exhibition in Manchester clearly shows that if a grand exhibition were properly organized in London the number of visitors to the Manchester Exhibition may be multiplied by ten, thus showing that there would be at least a clear balance of £10,000 after all expenses were paid. I think I stated that the expenses in connection with the proposed exhibition would amount to £20,000, but £16,500 would quite cover everything. "Oh ye of little faith," why have you lost such a golden opportunity? Why should your protectionist principles be allowed to "scotch" the wheels of horticultural progress? Such another opportunity may never occur again. The first gentleman in the land looked favourably upon the scheme, Her Majesty's Commissioners for the Exhibition of 1851 were willing that you should have the finest site in Europe for such a purpose, and a gentleman who will most likely be the first City dignitary next year, and a power in himself, offered his great aid in the cause, and also offered to become a liberal guarantor. Many other noblemen and gentlemen also offered their willing support, and their names are down for a very considerable amount. I fear the opposition shown by some exhibitors must be attributed to the fear of being defeated by younger men of the present day, and to their dread lest the star of their past successes should pale before the talent and energy which would undoubtedly be brought out by such an exhibition as that proposed to be held in London in 1880. That the depression of trade can have but little to do with the success of a great international horticultural exhibition properly organised is proved by the success which attended the Manchester Exhibition this year, a fact which must be plainly evident to all whose vision is not obscured by prejudice, and who are not afraid to compete in a fair and open field.

JOHN WILLS.

Mignonette and Bees.—Mr. I. E. Johnson, St. George, Utah, finds by continued experience that Mignonette is the most valuable plant for bee-pasturage—blooming early and continuing till nipped by frost—and he tells "The Rural New Yorker" that he has not a shade of doubt that a well cultivated acre of it would give a abundant employment all through the season for 500 colonies.

PLATE CLXXXV.

A GROUP OF BOUVARDIAS.

Drawn by CONSTANCE PIERREFONT.

Few plants are more easily grown, or more amply reward the care of the cultivator by the production of abundance of flowers than the *Bouvardias*, yet it is only with a limited number of growers that they are brought to perfection; and while those who are fortunate in this respect can bring them into flower during any month in the year, or have them in succession all the year round, the majority of those who attempt their culture fail not because they cannot grow them, but generally because they take too much pains with them in the wrong direction, such as keeping them in pots throughout the summer, and nursing them up under glass, whereby they are induced to make weak wiry wood and hard dry leaves, generally infested with insects. The chief point in the culture of *Bouvardias*, or, indeed, in that of any other class of plants, is to induce them to make strong, clean growth, and flowers will follow as a matter of course. *Bouvardias* should be treated according to the time at which they are required to flower, but as they are most useful when in bloom in winter I will first give the treatment which they should receive in order to have them in flower at that time. As the plants go out of flower they should be removed to a rather dry house in which there is a temperature of about 50°. Here they may be kept until the turn of the year when each shoot should be cut back to the last joint, and about a fortnight afterwards the plants should be turned out of their pots, all the soil should be shaken off the roots, and they should then be re-potted into small pots. They soon break freely, when they should be kept in a cool house until the first or second week in June, when they may be planted out in the open ground; they require but little attention during the summer beyond giving them a copious supply of water and an occasional watering with weak liquid manure. As growth progresses they should be pinched back to the last joint two or three times during the summer, and the weaker shoots should be continually removed, the last pinching back and thinning out being done in the last week in August.

About the second week in September they should be lifted and potted into suitable-sized pots, and placed in a cold frame, where they should be carefully shaded from the sun for a fortnight or so. They should be potted in moist soil (turfy loam) and not watered at the root for three or four days, but sprinkled lightly overhead night and morning. When the nights begin to get cold the plants should be removed to a intermediate house, i.e., one in which there is a temperature of about 50° by night and 60° by day. Here, if copiously supplied with water, and assisted occasionally with a little weak liquid manure, they will continue to bloom during the whole of the winter in the greatest profusion.

If *Bouvardias* are required for blooming in summer, a portion of the plants potted in the winter should be shifted into a size larger pot in the spring and kept growing. Although *Bouvardias* may be grown to perfection in an intermediate house, some of them, such as *B. longiflora*, *B. jasminiflora*, and *B. Humboldtii* corymbiflora, will even stand stove temperature and flower beautifully; but where much heat is given care should be taken to ventilate freely. To Messrs. E. G. Henderson & Son, from whose establishment were obtained the flowering sprays from which our plate was prepared, belongs the honour of having raised or introduced the greater part of the best *Bouvardias* in cultivation, and from these has been made the following selection, viz., *B. Vreelandii* or *Davisoni*, white; *B. Hogarthi*, scarlet; *B. elegans*, bright scarlet; and *B. Maiden's* Blush, pale rose. These four belong to the same section, and are the very best for outdoor summer culture. *B. Queen of Roses*, rosy-pink; *B. longiflora flammæ*, pale vermillion; and *B. candidissima*, snow-white, belong to an intermediate section, and form beautiful compact plants for winter blooming when grown in the open garden in summer. *B. Humboldtii* corymbiflora, the large white on the annexed plate, is very fragrant. To these may be added *B. jasminoides*, white; *B. umbellata* carnea, white changing to blush; and *B. flavesces*, pale yellow. Occasional sprinklings with weak Tobacco water in the evening are the best means of keeping *Bouvardias* free from insects.

JAMES O'BRIEN.

Paulownia imperialis.—This at present forms a striking object in pleasure grounds, its spikes of blue, *Gloxinia*-like flowers being very distinct from anything else in the way of flowering trees or shrubs. It is a tree about which much diversity of opinion exists as to its hardness, its wood being soft and succulent; but while *Laurustinus*, *Myrtles*, and similar shrubs were much cut up by the frost, the *Paulownia* has from every branch sent out quite a cloud of its singularly effective blossoms.—J. Groom, Linton, near Maidstone.

A GROUP OF BENTLEY'S

VEGETABLE CULTURE FOR MARKET.

MUSHROOMS.—Enormous quantities of these are disposed of in Covent Garden Market between September and April. In nearly all cases they are grown on ridges in the open air. Sometimes these ridges are built between fruit trees, but when an open space can be had it is always chosen in preference. They are placed so as to form a series of ridges 8 ft. apart. They consist of ordinary stable manure, from which the strawy part has been separated, and which has been previously turned over two or three times to sweeten and prevent fermentation, for the fresher the manure the greater are the chances of success. Whilst the manure is being prepared, the ground selected for the ridges is levelled and lined off into breadths 6 ft. wide with 2-ft. alleys between them; the manure is then wheeled along the rows and built firmly into bluntly-tapering ridges. When constructed, they are left exposed for a few days, in order that the heat, which is at first great, may subside to about 80°. If it gets too strong, the ridges are thrown down and rebuilt, an occurrence by no means uncommon; even whole fields of ridges in August and September may sometimes be seen thus overturned. When rebuilt and the proper temperature has been arrived at, they are at once spawned on both sides, after which about 3 in. in thickness of mould are spread over the manure and made firm by being well beaten with the back of a spade, leaving the surface smooth and even. The ridges are now left undisturbed for a few days, and if the inside be not likely to get too hot a loose covering of litter is placed over them, which is increased in thickness as the heat subsides. In hard frosty weather additional litter is applied, and mats are pegged down on each side of the ridges to guard them from wet. In this way frost is excluded, and also wet to a great extent, and the litter is prevented from being blown away by wind. Watering is seldom found necessary even in the driest situations or seasons; but when it is done all coverings are removed and the ridges are gently watered with a rose-pot, the water being used in a tepid state. When gathering the Mushrooms, the litter is carefully removed by one man; after him come others with baskets, into which the Mushrooms are collected; and, following the pickers, are other men who replace the covering, for it is an important matter not to permit the ridges to be at any time long exposed.

Market gardeners used formerly to make their own Mushroom spawn, but now they find it, as a rule, cheaper to buy it. The cakes into which it is made are broken up into pieces about the size of a Walnut, and these are inserted in three rows along each side of the ridges, from 9 in. to 12 in. apart in the rows. The first ridges are made about the middle or end of July, the main series about a month later, and some are often made in October. Dry frosty winters are beneficial to the Mushroom crop, and dull, damp ones the contrary; in very wet seasons even the best of cultivators often lose large sums of money in consequence of their crops failing. When the beds are exhausted, the manure, being thoroughly decayed, makes excellent material for applying to ground about to be planted with gross feeding crops, such as Vegetable Marrows, Tomatoes, Lettuces, Celery, French Beans, &c. Mr. Steel, of Fulham, and several other Mushroom growers, however, instead of removing their ridges, plant them with the earliest crop of Tomatoes, positions in which they ripen their fruit much earlier than in open borders. Mr. Elliot, to whom I have elsewhere alluded, is one of the most successful Mushroom growers in the neighbourhood of London; his ground lies high and dry, and he seldom loses a crop. In February, 1877, which was one of the worst seasons on record for Mushroom culture, I saw in his packing shed no fewer than a score of half-bushel baskets full of beautiful Mushrooms at one

time. The large ones were being separated from what are termed "buttons" and placed in baskets by themselves. The latter fetch the most money, but the former probably pay the grower best, inasmuch as it takes fewer of them to fill a basket. Mr. Dancer, of Chiswick, a very successful Mushroom grower, often produces large quantities in cold frames during winter; but in summer Mushroom growing in this way seldom repays the trouble incurred and the valuable space occupied. Mushrooms are also sometimes grown largely in Cucumber houses and similar places. When crops of Cucumbers are on the decline in summer, the beds are covered with warm manure and spawned, and from such beds bushels of good Mushrooms are gathered throughout the winter. The Cucumbers are allowed to grow at will or die, but are not pulled up, as the foliage even when dead helps to darken the house, and thus furthers the growth of the Mushrooms. In Vineries, too, where no Vine roots exist in the inside borders, Mushroom beds are made, *i.e.*, when sufficient heat is kept up in the houses to be favourable to their growth, which happens, of course, early in the spring. Perhaps this is as profitable a crop as can be employed to occupy such spare spaces, and if private growers, who are often short of a supply of Mushrooms, were to make up little beds in succession in similar positions, they would probably always have plenty. Growers of Mushrooms always try to get a good crop into market shortly before Christmas, as they are at that season in great demand.

TOMATOES.—During the last few years Tomatoes have risen rapidly in public favour. At one time there was comparatively little demand for them, but now acres of plants are grown where formerly there were only dozens, and hundreds of bushels of fruit are yearly imported from America. As an indoor crop, Tomatoes do not always pay the grower unless he has plenty of house-room that would otherwise be unoccupied. American growers can produce fruit much earlier and at less expense than English cultivators, who have to pay high rents and high prices for forcing material; and for this reason only a few people near London attempt the growth of the Tomato as an early indoor crop on anything like a large scale. Mr. Wells, of Barnet, grows his Tomatoes in beds of soil that previously had been occupied by Cucumbers, and even then the soil, he informed me, was rather richer than he could have wished, for if it be too light and rich in character Tomatoes make rank growth at the expense of fruit. The plants which I saw, however, at Barnet, were loaded with bloom, and promised to bear heavy crops. The variety grown was unnamed, but seeds of it were obtained from a grower at Sherborne, who exhibited it at South Kensington some few years ago, and so well does it answer the purpose that Mr. Wells has never grown any other. One year he put out a few plants in a bed of burnt ballast out-of-doors, and although they did not grow very luxuriantly, and did not ripen their fruit perfectly, owing to their being planted late, yet the crop was a heavy one, and the fruit, which was picked green and ripened on a shelf in one of the houses, fetched in the market in November about 2s. per dozen. Mr. Bennet, of Rabley, grows Tomatoes in beds in houses in the same way in which Vines are grown. The first crop, being brought on early, yields fruit in April. The plants are obtained from seeds or cuttings, planted in the beds in which they are to fruit in January. They are subjected to plenty of heat and moisture and receive abundance of water at the roots, and thus treated they yield heavy crops, which ripen in April and May, and which are sold in the market at remunerative prices. Stopping the shoots frequently and fertilising the blossoms are important points in Tomato culture both indoors and out,

inasmuch as both operations not only increase the quantity of fruit, but also its size and quality.

Outdoor Tomatoes in market gardens are not planted against walls, as is done in private establishments; but a warm situation, convenient to water, is selected for them in open positions, and in such positions they produce abundance of fine, large, well-coloured fruit. The earliest planted ones are generally put in the most favourable positions, such as a warm border, or on either side of "spent" Mushroom ridges, where they are well sheltered. If planted too early, they are liable to be cut down by late spring frosts, in which case entire removal and replanting is the remedy usually applied; if the damage be not too great, however, the sound eyes produce shoots that eventually carry heavy crops. The large red-fruited sort, which much resembles the Orangefield, is the principal kind cultivated in London market gardens; and growers for market will not be easily persuaded to exchange it for any of the novelties that have lately appeared among Tomatoes. It is an abundant bearer, hardy, and, although its fruits are not so shapely as those of many other kinds, they are excellent in quality. Early in spring, the seeds of this kind are sown broadcast in a frame, in which a bed of fermenting manure, covered with 6 in. of light soil, has been placed. These frames are protected during cold weather by a covering of litter or mats placed over the sashes; but during favourable weather this is removed and air is given, in order to render the young plants as strong, healthy, and stubby as possible. If the plants come up too thickly they are thinned, and when they are about 2 in. high they are pricked out into 4-in. or 6-in pots, two plants being generally put into each pot. Frames are sometimes prepared by placing in them fermenting manure in the form of a bed to a depth of 15 in., well trodden down, on which are placed 8 in. of soil, and in such beds pots filled with mould are plunged up to the brim. The plants are then dibbled into the pots, and the frames shut up and kept close for a time, until fresh root-action has taken place. They are afterwards kept freely ventilated until May, when the sashes are entirely removed during the day, and replaced and tilted up at night and in wet weather. During the last week in May and first fortnight in June the plants are thoroughly hardened off, although still unable to endure even a slight frost, and they are planted in warm positions, as before stated, on Mushroom ridges or similar places. As soon as the fruit has attained its full size, the leaves are turned aside so as to expose it to the sun, by which means it ripens more readily, and is of a better colour than when shaded. The ripe fruits are generally picked off twice a week, leaving the greener ones a little longer, so as to mature themselves; but should frost come, all fruits are picked off, and spread out on hay in a frame under sashes, where they eventually become red. The amount of fruit borne by a patch of Tomatoes in a well-managed market garden is really wonderful. Good Tomatoes of outdoor growth fetch £1 per bushel in Covent Garden, and some large growers gather as many as eighty bushels per week. Some idea of the extent to which Tomatoes are grown in the Fulham Fields may also be gleaned from the fact that some of the "quarters" hold upwards of 10,000 plants, and that some growers have several such quarters.

CUCUMBERS.—Of these thousands are sold in the London markets nearly every week in the year. As an indoor crop either in winter or summer under favourable circumstances, Cucumbers rank amongst the most profitable, and as an outdoor crop in warm localities or in temporary frames, Cucumbers yield good returns, and there is never too many of them, for what cannot be sold in the market are speedily bought up by pickle merchants.

CUCUMBERS IN HOUSES.—One of the most extensive growers of Cucumbers in houses is a market gardener at Potter's Bar, who has many houses devoted to their culture, and the quantities cut every year for market are almost incredible. In one year over 25,000 Cucumbers were sent from this place to London, which represented some £500. They are principally grown in low span-roofed houses, with 3-ft. beds on each side, and in some cases a bed in the centre is devoted to Melons, the Cucumber plants at the sides being kept sufficiently within bounds not to injure the Melons by their shade. The Cucumber seeds are sown in the autumn, from which strong plants are obtained to furnish the winter supply; these are planted in loam and manure, and continue in bearing until spring, when they are succeeded by others planted out later in the season. During the summer Cucumbers are not grown here to any great extent, as, owing to such large quantities of outdoor or frame-grown ones coming from all the market gardens round London, house room is too valuable to be occupied by them. Cucumber-growing in market gardens is carried on on a system very different from that practised in private gardens. Where market growers spend 20s. in fuel and other matters connected with Cucumber growing, a private cultivator, as a rule, spends 30s., and where the latter cuts one Cucumber from a plant the former cut six.

One of the best examples of Cucumber-growing with which I have met, considering the primitive character of the houses and other means at command, was in Mr. Wells' garden, near Barnet, a place somewhat low-lying and otherwise by no means favourable for such a crop; indeed, Mr. Wells informed me that his out-door fruit trees, of which he has some remarkably healthy specimens, have never yielded him any fruit worthy of mention for many years, and in the spring of 1877 when I visited his place, the blossoms of Apples, Pears, Plums, Strawberries, and other outdoor crops were completely ruined by frost, while scarcely a mile off the blossoms of fruit trees in other gardens were uninjured. But it is Mr. Wells' indoor department with which we are now most concerned, and certainly when we take into consideration the character of the glass structures as well as their exterior arrangements, the results obtained from them are truly astonishing. There are in all about a dozen glass houses, chiefly span roofed, and most of them are devoted to Cucumbers. These houses are each about 100 ft. in length, and are sunk to a depth of 3 ft. or 4 ft. A pathway runs through the centre of them, and on either side are beds about 3 ft. wide in which the plants are grown. In some cases these houses are placed side by side, and instead of having partition walls the roofs of the houses adjoining are supported on brick piers built from 5 ft. to 6 ft. apart, a plan which admits of a free circulation of air, and at the same time economises heat; indeed, to free circulation is no doubt, to a great extent, due the marvellous results obtained, for there is no other apparent cause why Cucumbers should thrive and bear better here than they do in other places, but such is the fact. The heating apparatus is by no means elaborate; indeed, one would almost imagine there was too little piping to keep early Cucumbers at a proper temperature. The only variety grown here is the Rabley, a short-fruited, prolific kind, which meets with a ready sale in the market on account of its excellent flavour, and owing to its being but small the fruit can be sold at a cheaper rate than if it were larger, a matter of no small importance in the case of early Cucumbers, for Mr. Wells informed me that where he could grow one good fruit of Telegraph—a variety which he formerly grew to a large extent, and which he still considers the best variety in cultivation for private establishments—he can grow two at least of the Rabley, and he finds no difficulty in disposing of them; whereas, when he grew Tele-

graph he had often to sell it at an unremunerative price. All Cucumber plants here are raised from seeds sown on the place; a little house is provided in a sheltered situation for raising them; the seeds are sown in small pots plunged in beds of Cocoa-nut fibre, and when up the plants are potted into 4-in. pots, out of which they are transferred, when ready, to the beds. The first sowing takes place early in December, and the first house is planted early in January; five weeks afterwards the plants are sufficiently advanced to bear a moderate crop. Soon after this two, or perhaps three, more houses are planted to succeed the first, and when the plants in the latter begin to bear fruit those in the first house are pruned and allowed a few weeks rest, in order to enable them to bear large crops when Cucumbers are most in request. The remaining four houses are planted all at one time, and the plants in them continue to bear enormous crops until September or October, after which time they are done away with, and the houses are devoted to other purposes. The earliest houses are furnished with six rows of 3-in. piping, one row being placed on each side of the house, and a double row along the beds on each side of the pathway, the later houses having simply a flow and return pipe running all round them. The soil used here for Cucumber growing is such as is obtained from the garden outside, mixed with a quantity of half-rotted stable manure, and after it has been used one year it is returned to the garden whence it came, and being considerably enriched the whole garden in time becomes improved. Bottom-heat is never used here even in the case of early houses. The beds in which the Cucumbers are planted consist of stiff clay to within 1 ft. of the top of the wall which surrounds the beds. Above the clay is placed a ridge of soil 8 in. or 9 in. in depth, and into this the plants are put 2 ft. apart: occasional mulchings of manure are given when the roots appear on the surface, and abundance of tepid water is at all times applied to the soil. The plants are in all cases trained up wire trellises fixed about 1 ft. from the glass, the main shoots being led upwards until the points are within 1 ft. of the middle rafter directly over the pathway, when they are stopped, an operation which causes them to break strongly at every joint. After this stopping is practised regularly in order to ensure as large a crop as possible, each shoot being pinched off at one joint beyond the fruit. The labour involved in stopping, tying, and regulating the shoots during the summer when all the houses are in full bearing, is very great, as all those who know the time which it takes to keep one small house in order will quite understand, and on an average, from this place alone, 30,000 Cucumbers are cut yearly for market. During the spring the houses not occupied by Cucumbers are filled with Straw-berries.

In another garden near London, of no great extent, marvellous results are also obtained in the way of Cucumber culture. The houses in this case are furnished with troughs made of rough boards about 10 in. deep and 3 ft. wide. Into these troughs soil, consisting of loam, road-grit, and horse-manure, is placed, leaving plenty of room for top-dressings. This plan answers perfectly, as slight dressings, frequently applied, maintain health without over-stimulating. The point most noticeable is the small modicum of soil allowed for the plants to grow in. They stand about 2 ft. apart; they are grown with straight stems about 12 in. or 18 in. long, and are trained on temporary trellises 1 ft. from the glass, which is evidently not far enough, as both cold and sunshine affect them at that distance. The heat is supplied by means of flues—that is, 9-in. socket pipes put together with cement do duty as brick-flues. A row of these pipes is carried under the middle of the troughs. In

excavating the path, the earth at the sides is left; on the top of this runs the pipe-flue, almost close to the bottom of the troughs in which the plants grow. This flue is the only source of heat; in severe weather straw mats are put on, and are found to be of great service. The cubical contents of one of these structures is very little; and, limited as the surface is, it can readily be covered up to economise the heat needed inside. The plants for bearing all spring and summer are put out in the early part of winter; the object being to have plenty when the demand is good. The quantity of fruits produced in these small houses is something marvellous. They are cut three times a week, and supplied direct to the consumers—only the rough ones are sent to the market for what they will bring. The sort which this grower prefers above all others is Sutton's Perfection. C. W. S.

AMERICAN NOTES.

About a Wild Garden.—The idea of the wild garden is being taken up well in America judging by the following: I wish I were sure that this could catch the eye and have the attention of the many who really love flowers but, for one reason or another, have no garden. Many a country dweller who intends to have a flower garden looks upon it as an undertaking that requires an outlay of time, labour, and money. It is to be in the good time coming, and in the meantime he gratifies his love for flowers by occasional rambles to see what the woods, the meadows, and the coppices afford him. Now suppose that instead of tramping for some miles for a few wild flowers, these could all be found—not only these, but a great many more—all within the area of a few yards! Would he not rejoice at it? This is just my idea of a wild garden. A nook somewhere—not already too much crowded with natural growth, where the roots of trees and shrubs will take all that the soil has to give—but a good bit of unoccupied ground. Here put all the native flowers that are desirable, with a whole host of hardy plants from other countries. There are few places that do not afford such a spot—no matter if it be at a distance from the house; this garden has not to be watered, watched, and tended. But there may be those who, like myself, prefer to make a wild garden. Our wooded hill-side is too far off, though that is more or less planted, and even the pasture has a corner penned off for moisture-loving plants. There is not much wild about my wild garden save the plants. The fence is hidden by a row of closely planted evergreens. A side is made "wild" by a drapery of Virginia Creeper and Wistaria, and in this corner is

A Rockwork.—This rockery, of the stones at hand, was made with but one object in view—growing plants. It would defy any geologist to account for its upheaval, especially as it is mainly of new red sandstone, the worst of all rocks for the purpose, but all that we had. Of natural rock scenery there is little, but of cracks and crevices there are many. The ground around the rockery for some distance forms a part of the wild garden. Last autumn we had a goodly collection of plants from Europe, but I was away when they were planted, so this spring I had not only the pleasure of seeing the plants, but of making new discoveries. I have read of an eccentric literary man, whose name I have forgotten, who was very fond of confectionery; one of his oddities was to hide sugar-plums and the like in all sorts of odd places, that he might enjoy the pleasure of finding them unexpectedly. My first visit this spring to the wild garden reminded me of him, in discovering new plants in unexpected places, and I could understand his satisfaction over his discoveries of hidden sweets.

Plants for the Wild Garden.—While in almost every locality there are sufficient flowers to make a wild garden attractive, and one is worth having for these only, there are a great many from other countries that are able to make themselves quite at home, and become naturalised. Of course the wild garden will have a succession from early spring until the frost puts an end to all bloom, and this mentioning of those that greeted my first visit is intended only to show some of the early blooming plants that may be introduced. At the foot of the rockwork was a sheet of brilliant white, than which nothing could be more beautiful. Yet it was only the common Blood-root (*Sanguinaria canadensis*). Near by, that best of early spring bulbs, *Bulbocodium vernum*, earlier than the Crocus, and in a mass more showy, had nearly gone out of flower. Another charming early native is the Rue Anemone (*Thalictrum anemonoides*), delicate in foliage and habit, and bearing an abundance of small white flowers which have not the brilliant opaque white of those of the

THE INDOOR GARDEN.

Blood-root, but in their way are quite as pleasing. This is one of the few flowers that show a tendency to become double in a wild state. But speaking of doubles, I know of none of our wild plants that produce such beautiful double flowers as the Hepatica or Liver-leaf (*Hepatica triloba*). It is common in the woods, at least in all the Eastern States, flowering as soon as the snow is off. It is also a native of Europe, and Europeans have secured a number of double forms possessing a variety of colours. I have found it wild varying from nearly a pure white to the deepest blue, but never saw any tendency to doubleness. There are, however, double white, pink, red, blue, and purple, with intermediate shades, and each one a gem in itself. I find that we have quite a collection of native and foreign species of *Erythronium* or Dog's-tooth Violet. Our common *Erythronium americanum* is welcome, but when it comes to the question of beauty the European *E. Dens-canis* is far ahead of it. In beautiful contrast to this is the White Dog's-tooth Violet, rare in the East, but common in the far West, and well worth having. Those who like oddities in the way of plants will admire the *Asarum* or Wild Gingers. One species, known as Canada Snake Root, is common in all the Northern woods. These, with two Southern species, another from Oregon, and one from Europe, make up a group which, while not showy, are interesting. When we come to showy plants in the wild garden, we find *Aubrietia deltoidea* quite a sheet of delicate purple. In a corner there is the Winter Aconite, one of the earliest of all, and a little later, *Adonis vernalis*, with flowers of a brighter yellow, and foliage so dark green and beautifully cut that it would be worth growing for that alone. Close after *Adonis* comes the slender-leaved Peony (*Paeonia tenuifolia*), double and single, so beautiful with their rich crimson flowers, fine foliage, and withal so rare. The Grape Hyacinth (*Muscari botryoides*) naturalises well in the wild garden, and both the dark blue and white kinds seem to be quite at home. Among other native plants worthy of special notice are *Dicentra Cucullaria*, three-flowered Gum (*Gum triflorum*) from the far West, and more showy in fruit than in flower; the American Pasque Flower (*Anemone patens* var. *Nuttalliana*), its large flowers making it noticeable. But it would make too long a list to name everything, my object being to commend the wild garden to every lover of wild plants. Our natives can grow there, and a large number of foreigners may be naturalised and made wild. It can be made a source of great pleasure to those who can have no other garden, while to those who have the most formal borders it will be a pleasing change to have a nook or corner where their favourites can be at home.—“American Agriculturist.”

Water Melons.—Mr. E. A. Riehl, Alton, Ill., tells the “Rural World” that he has cultivated every Water Melon usually described in seed catalogues, and discarded all but the Ice Cream—each specimen of which he finds of the highest excellence, unlike other varieties which produce “a few choice ones and the majority poor.”

Roots in Water Pipes.—Mr. T. S. Gold, of West Cornwall, in a communication to the “Connecticut Farmer,” mentions the obstruction of water caused by a bunch of hair-like roots about 15 in. long, all growing from one that had found its way through a little hole in the 6-in. lead pipe, which it completely filled.

The Plough in the Garden.—Mr. W. F. Clarke prints in his “Western Advertiser” columns a plea for “The Improved System of Farmers’ Gardens” frequently suggested in “The Tribune”: “Select a piece of land, unencumbered with trees or even bushes, affording free scope for the plough. Discard beds and sow everything in long rows far enough apart to admit of tillage with the horse hoe. By adopting this method hard labour is reduced to a minimum. It will cost but a little extra trouble to have sufficient good manure on hand to make the land capable of growing everything sown in it to such a pitch of perfection as to be a constant source of pride and pleasure.” We copy this to give those who cultivate in the old-fashioned, laborious, non-effective way an opportunity to compare the obvious advantages of the proposed improvement over the objectionable garden plan of our forefathers, which kills weeds only at the cost of persistent hard work with rake and hoe.

May Bugs.—Mention is made in English records of 1747 of the collection of eighty bushels of the larvae of the May bug on one Norfolk farm. The same pest is now very destructive in France, it having been stated at a sitting of the Paris Central Horticultural Society that in one instance eighty-seven days of labour were expended on an acre, each man disabling 5000 of the grubs daily. The most effectual warfare seems to be to fight the bugs themselves, and one member spoke of having so successfully employed school children to collect them in cans and kill them with boiling water that he has not been much molested since.

SELAGINELLAS—THEIR USES AND CULTURE.

ALL who have glass houses should grow some of the many beautiful forms of Selaginellas, for not only are they plants of extremely easy culture, but they delight in situations in which the generality of plants would only linger and die. A saturated atmosphere, combined with partial shade, is what suits them best, and if planted in good free soil, they attain in such positions a high state of luxuriance, forming a verdant carpet ever fresh and beautiful, and which even the dulllest days of winter have not the power to dim. Selaginellas exhibit considerable variety of foliage, and a collection of a dozen varieties of them forms a very attractive feature in any glass structure. When mixed with fine-foliaged and flowering plants they add much to the beauty of the arrangement; in fact, plant groups cannot be set off to advantage without them. Vast quantities of *S. Kraussiana*, commonly, but erroneously, called *denticulata*, are grown by the London florists for this purpose alone, and well-furnished specimens in 4-in. pots command a ready sale in Covent Garden Market. This kind, being of a very hardy, enduring character, is preferable to all others for general decoration, but other varieties may be used in the same manner. I once saw some of the varieties employed in a very pleasing manner. They were grown in large pans, and were fine masses of healthy, well-developed foliage. As placed, they constituted an edging to a bank of fine-foliaged and flowering plants, forming a bright, fresh belt of verdure, the effect of which was intensified by the white stone floor and the bright flowering plants in the background. Many kinds of flowering plants, when in bloom, are so overpoweringly brilliant that they require the association of green-leaved plants. They do not in themselves possess verdure enough to counterbalance the glowing mass of colour which they display. Tulips and Azaleas, for instance, gain much by being surrounded by a fresh, cool carpet of verdure; in fact, there are few flowering plants whose charms are not enhanced by this combination. Many of these Club Mosses will thrive very well in a dwelling house, and if placed during summer in a shady situation, and occasionally taken out and well syringed, they will maintain their beauty for a long time. Some of the kinds may even be placed during summer in the open air, and if a cool, moist situation be chosen for them they appear to enjoy the exposure. *S. Kraussiana*, indeed, appears to be quite hardy in some parts of England, and we shall probably find in the course of time that many others are of a more enduring character than is now supposed to be the case.

Although Selaginellas are easily cultivated, they nevertheless require in order to have them in perfection a good free soil. Drainage, too, is an important point, as, owing to the necessity for constant waterings, unless the superfluous moisture can pass off freely, damping is almost sure to take place. Any great depth of soil is unnecessary; 6 in. of well prepared compost will suffice to maintain Selaginellas for years. A good mixture for this purpose consists of leaf-mould, peat, and river sand in equal proportions. In such a compost any of the kinds may be relied on to succeed, although some of the strong-growing varieties enjoy the admixture of a little loam and well-rotted manure. It is often stated that Selaginellas should be renewed yearly. This, however, entails more labour than many can well afford, neither is it indispensable, as if the planting is carefully done, and the whole of the turf clipped over in early spring, it may be maintained in good condition for years. When allowed to run into the second year without clipping, it becomes drawn and weakly at the bottom, and is then apt to die off in large patches; whereas, if closely shorn off a new growth is made, and fresh life and vigour are infused into it sufficient to carry it on for another season. A few potsful of this kind should be grown by those who have apartments to decorate. A dozen good strong well-rooted pieces, dibbled into a 4-in. pot, and placed for a time, until well established, in a close warm house, to be removed to a cool structure to complete their growth, will form fine specimens by the winter. Many who grow this variety in pots commit the error of placing the plants close together. Such a practice has the effect of preventing the formation of a mass of healthy foliage round the pot, and unless the pots are nearly concealed the utility of this plant is greatly impaired. Each plant should stand quite free from its neighbour during the growing season. Plants thus treated will be found immeasurably superior to those which have been allowed to intermingle one with each other, and will be of great service for many purposes.

S. apoda is an extremely neat, dense-habited species, well adapted for forming a narrow border on the stages of stoves and Orchid houses; it may also be used with good effect in combination with other plants such as strong, free-growing Ferns. If, when the Fern is shifted, a few tufts were pricked in round the edge of the pot by the time the Fern has become fairly established and filled the pot with roots, the Selaginella will have covered the surface soil with a fresh green carpet. This species is also admirably suited for Warden cases,

and it may be grown to great perfection in an ordinary sitting-room, if covered with a bell glass. Very pretty and interesting specimens may be formed by associating it with some of the dwarf species of Ferns such as *Asplenium Trichomanes*.

S. helvetica and *caulescens* may be both utilised in the same way, as may also *mutabilis*, a highly interesting species, owing to the fact of the foliage changing to white towards evening. Those who grow plants in rooms should certainly include in their collection one or more of these kinds; they are always fresh and bright, and are so easily managed, not requiring, if treated as above recommended, any attention for days together.

S. Kraussiana and *helvetica* may, if need be, be turned to good account in the sub-tropical garden. They luxuriate during the summer months in shade and moisture. When used for carpeting the soil between Tree Ferns, Palms, and other fine foliaged plants, they

that metallic hue which constitutes its chief charm. *S. africana*, *atro-viridis*, and *erythropus* are all fine, distinct, strong-growing kinds, that will repay liberal, careful culture. They may be grown into fine plants in wide shallow pans so drained as to allow of frequent moistenings. In early spring they should be shaken out and fresh potted, placing them on a damp bottom, where a certain amount of filtered light is admitted to them. In Orchid houses and stoves which have open stages many such positions may be found, and it would in all cases be better to thus utilise and beautify such situations than, as is often the case, to allow them to remain bare and unsightly. If a body of soil some 6 in. thick be placed underneath the stage, and the Mosses planted out in it, they will flourish there with but little trouble, and will add much to the general good appearance of the structure.

Byfleet.

J. CORNHILL.

Davallia (Microlepia) hirta cristata.

Nephrolepis Duffii.

not only find there the atmospheric condition essential to their well-being, but they enhance in a considerable degree the beauty of those plants with which they may be associated. On rockwork, again, in winter gardens, where natural effects are aimed at, many of the *Selaginellas* may be made to play an important part. Some of the large-leaved kinds, and the climbing species *cresia arborea*, if allowed to ramble freely and unrestrictedly, present a very graceful appearance.

S. cresia and its variety *arborea* are two very distinct and attractive kinds. The foliage of both varieties displays tints very uncommon in plants, and the last-named kind is doubly valuable on account of its climbing habit. Under favourable circumstances it makes shoots some feet in length, and may be trained up the trunks of Tree Ferns or the back walls of hothouses, or it may be made to clothe the supports of the plant stages. It is a free-growing variety, but requires a warm, humid atmosphere, otherwise it fails to exhibit

Davallia (Microlepia) hirta var. cristata.—This elegant variety of the widely dispersed *Davallia hirta* was imported by Mr. B. S. Williams from the South Sea Islands, where the crested form appears to be rather frequent. It is an admirable Fern for baskets and broad pans, the feathery extremities being exceedingly light and graceful. The accompanying figure represents the extremity only of a frond.

Nephrolepis Duffii.—Probably a crested variety of either *Nephrolepis exaltata* or *N. cordifolia*, both of which have a wide range of distribution; but, so long as only sterile fronds are known, it is not easy to settle this point, as the most important distinction between the two species is in the fructification. This beautiful Fern was collected by Mr. Duff, of the Sydney Botanic Garden, in the Duke of York's Island, one of the Union group in the South Pacific, and was imported into this country by Messrs. Veitch, by whom it has been distributed.

L A W.

HOLE v. BRADBURY.—This action was brought for infringement of the copyright of a book called "A Little Tour in Ireland, by an Oxonian, with Illustrations by John Leech." The work was the joint production of the Rev. Samuel Reynolds Hole (now a Canon of Lincoln) and the late Mr. John Leech, who were intimate friends, and who in 1858 made a holiday tour in Ireland, Mr. Hole contributing the writing and Mr. Leech the sketches of the book they completed on their return, which was published by Messrs. Bradbury & Co. in 1859. The publishing arrangements were made by Mr. Leech, and he appeared to have verbally made the ordinary publisher's agreement with Messrs. Bradbury for half profits. No written agreement was made, but Messrs. Bradbury's books showed an allowance of half profits to the authors. The work had been successful to the extent of the sale of 3000 copies. Mr. Leech died in 1864, leaving his property to his widow, upon whose death, in 1865, the co-plaintiff, Miss Ada Leech, became her sole next of kin, and entitled, by the Copyright Act, to stand as the personal representative of Mr. Leech. Bradbury & Co. had reprinted the work without the consent of either of the authors or their representatives, and the plaintiffs now contended that the registration of the copyright in their name was *prima facie* evidence of their title under the statute, and asked accordingly for an injunction against the defendants, for an account of their receipts from the work, and for the delivery up of Mr. Leech's drawings and blocks by the defendants, Mr. Hole being in possession of the manuscript of the book. The defendants claimed to be themselves entitled to the copyright, and represented that the arrangement with Mr. Leech (who was in their employ for illustrating "Punch") was that he should furnish sketches during a trip to Ireland in 1858, the plaintiff, who accompanied him as a friend, arranging to write the letterpress, but the book was to be the property of the firm. It was completed the following year on a second visit to Ireland by Mr. Leech, in company with Mr. Mark Lemon, then editor of "Punch," and then Mr. Leech agreed to sell the book to the defendants' firm on the terms that any loss was to be sustained by them exclusively, but half of any profits were to be paid to Mr. Leech. That arrangement was ratified and confirmed as the defendants alleged by the plaintiff, Mr. Hole.—His lordship held that an injunction must be granted as prayed, restraining the defendants from publishing, and an account of profits must be rendered by them. They must also deliver up Mr. Leech's drawings and the blocks, and pay the costs of the action.

GARDENING FOR THE WEEK.

Flower Garden.

With such cold wet weather as that which has now prevailed for many weeks past it is quite a relief to be able to say that bedding out is finished; growth is quite another matter, yet, though this has been little, it has been sufficient to justify a hope that all will presently come right; but, in the meantime, no cultural effort should be spared to attain perfection in the way of display at the earliest possible period, for the longest season during which bedding plants continue in perfection is far too short when the expense and pains requisite to produce it are taken into account. As soon as fine weather sets in stir the surface soil of the beds, for the rains harden it to such an extent that if not moved it soon cracks, and growth is checked. A small hoe or hand fork can be used for this purpose, except in the case of carpet beds, which, being planted thickly, a hoe cannot be used; recourse must therefore be had to a sharp-pointed stick, with which a handy boy will stir up many beds in the course of a day. With an eye to effectiveness, let all groundwork, edgings, and divisional lines be kept true to design by frequent and regular pinchings or peggings; if time thus to keep them in order cannot be afforded, no attempt at geometrical arrangements should ever be made; on the contrary, preference be given to masses of colour arranged in lines or circles, broken at regular intervals by means of "dot" plants, in order to obviate the monotony of flat surfaces. All kinds of bedding plants will be the better for having their flower-stems picked off till growth is established; at all events none should ever be allowed to seed, which *Violas* and *Fansies* are already doing, and if not picked over they will soon give up flowering. *Calceolarias* never fail to flower throughout the season if their flower-stems be pinched off once after planting, and the same may be said of *Lobelias*, which we clip over with sheep shears. Tall bedding and sub-tropical plants will require support, which it is best to provide at once, ere injury accrues through storms of wind or rain. Small twiggy branches make excellent supports for all plants that do not exceed 2 ft. in height, such as *Petunias*, *Perilla*, and *Calceolaria amplexicaulis*; but all large-growing sub-tropical plants must

have separate stakes proportionate to their height, and the same remark applies to *Dahlias* and *Hollyhocks*, the growth of which is more robust than usual. Standard *Roses* may also require renewal in the way of stakes lest their heads get overweighted and break off; keep them free from suckers, and in showery weather sprinkle the beds with soot or guano, as where neatness has to be studied, surface mulchings of rotten manure—the best stimulant—are not always practicable. Keep dead and decaying flowers picked off, and as soon as any have done flowering, more particularly those of a straggling habit, shorten back the shoots in order to induce a second bloom. Complete the thinning and planting out of annuals; this has been a favourable season for such work, and if properly done a fine autumnal display may be expected, *i.e.*, if the plants be protected from slugs, which unfortunately are very numerous. As soon as planting is finished, there should be a general clearing up of walks, clipping and trimming of edgings, or any other operation that may conduce to neatness.—W. W.

Auriculas.—The earliest potted plants are now making strong healthy growth, and afford a striking contrast to those not potted; the latter have also made growth, but the difference between the two is easily recognised, and the leaves are not nearly so richly coloured. A few of the seed pods show signs of ripening, and as soon as the seeds are gathered they will be sown, and the pots placed in a hand-light or cold frame behind a north wall. A correspondent asks, "What am I to do with plants that have finished flowering?" The answer is, pot them at once, and place them in a frame behind a north wall or some similar position. Keep the frame close for a few days, but not quite close; tilt the lights at the back an inch or two. In potting remove nearly all the soil and examine the tap root; this is often in a state of decay, but whether it is so or not, it ought to be shortened. Let the soil be light and moderately rich; it should be composed of, say, four parts turfy loam, one of leaf-mould, one of rotten manure, and some sharp sand. The largest plants may be potted in 5-in. pots, and the smaller examples in 3-in. ones. Overpotting is a great evil. I potted three plants of a very choice variety some two months ago. One was a little larger than the others, and I ventured to pot it into a 4½-in. pot; the other two were potted into 3-in. ones; the result being that the two in small pots are now the largest and healthiest.

Carnations and Picotees.—These are now making exceedingly good growth, and the plants are as healthy as I have ever seen them. See that the more common kinds in beds and borders are kept clean; they are sometimes attacked by a maggot which eats into the centre bud. This, when perceived, must be destroyed, even if the bud has to be sacrificed.

Hollyhocks.—Those who have a clean stock of the best-named varieties of these are fortunate, and should be careful how they introduce plants from other places amongst them, for the *Hollyhock* fungus has exterminated many fine collections. It is of little use trying to combat this disease in any way except by burning the plants root and branch.

Gladioli.—These, although they started slowly, are now improving rapidly, their growth being strong and the foliage deep green, a sign that in time we will have healthy, well-developed spikes of flower. It is singular how this plant degenerates in our climate; even seedlings in the course of a few years fall off rapidly as regards constitution, although in quality the individual flowers do not suffer at all. Seedlings are easily raised, and flower strongly the year after sowing. I usually sow in pots, raising about thirty plants in a 7-in. pot. These require careful treatment during summer, and when the leaves die off the soil is shaken from the roots; they are then packed away, each sort in paper, with a very little dry sand amongst the roots.

Tulips.—The leaves of these are beginning to assume a yellow tinge, and in ten days, or at most a fortnight, we will dig them up and store them away in a dry place, taking care that none of the labels get displaced. The old *Tulip* growers did not use labels, nor do the principal growers now; they enter each variety separately in a book, marking one end of the bed and working to the other end. That glass coverings are an advantage has been shown by the Rev. F. D. Horner having carried off all the principal prizes last week at Manchester, and it is a question whether a light glass structure is not in the end quite as cheap as the iron framework and thick cloth coverings that are so much used, the wear and tear of material and the labour involved, to say nothing about untidiness, being very considerable. What does Mr. Horner say to both systems after having given them both a trial?

Hardy Cyripediums.—What is the best time to pot these may well be asked. This is an operation which I used to perform in winter just before the crowns began to move, and I have been very successful. This year some of them have been repotted in full leaf,

all the soil being removed from the roots first. I thought this would not answer, but I have been much pleased to see the plants gradually becoming stronger, and some potted three weeks ago are well established. The largest proportion of them take more kindly to turfy loam than peat; the roots do not seem to start into active growth until the top has grown very considerably; and in all my experience as regards growing Orchids, I find that the best time to repot is just when the roots begin to grow.—J. DOUGLAS.

Conservatory.

This structure will now, when spring-flowering, hard-wooded plants—including Azaleas and others—are over, be dependent for a display on summer blooming plants alone. The large-flowered Pelargoniums, like everything else influenced in their progress by the more or less sunny character of the weather, are this year more than usually late, and such as in ordinary seasons would be getting over will at the present time be about their best. The nature of these plants is such, that they are very impatient of any excess of water, but, being as they are, if skillfully managed, furnished with a mass of feeding roots that completely permeate the soil, they should in dry weather be examined as to their requirements in respect to water twice a day, for if ever allowed to get dry to an extent that will cause them to flag even slightly, every expanded flower will fall. The bloom of almost any plant at this season is of shorter duration than earlier or later when the weather is cooler, and to keep up an effective display, nothing must be left undone to prolong the bloom to its full extent; shade the roof during the daytime as far as may be requisite, and do not allow the atmosphere to get into that parched condition often met with in conservatories, and which, especially when the sun is on the glass, is alike hurtful to the plants, and renders an inspection of them disagreeable. In such houses water cannot be thrown about the floor to moisten the atmosphere in the way in which it can be done in some structures, as it makes the paths unpleasant to walk upon; but a good deal can be done by keeping the borders in which climbing plants are grown sufficiently moist, and if the whole of the stock, so far as it requires water, be attended to the first thing in the morning, whatever is spilt about will get dried up early enough, and the moisture from the newly watered soil in the pots will do much to correct the drying influence of the sun and air; for this reason, and also on account of the plants, should any happen to be dry through having escaped the eye of the attendant, it is much better to do the general watering in the morning than to defer it until evening, though in the case of many plants that occupy small pots, and these very full of roots, in exceptionally hot weather it is necessary to go over them at both ends of the day. Connected with this matter of watering, it may be well to mention as a reminder that if any plant be discovered in the middle of the day that has got very dry, it ought at once to be removed to a shady position before water is given, for there is not anything more likely to cause death than the application of water to the roots of a plant when the soil has been allowed to become very dry, if standing where it is only under the partial influence of the sun.

Fuchsias.—The first portion of large Fuchsias will now be in full bloom, but unless means be taken to keep them going, their flowering will soon be over. The plants should be gone over twice a week, in order to remove the seed-pods as soon as the flowers have fallen, to the formation of which some varieties are much more disposed than others, and if allowed to remain on the plants they have a more exhausting effect than the production and development of flowers; but even with this attention, if the plants be not kept in a state which enables the shoots to keep continually extending, the blooming is necessarily soon over. Fuchsias like manure-water, but it is necessary to give it them much weaker than to many plants, otherwise it causes the buds to drop off in quantity before they expand. Instead of giving it to them periodically somewhat stronger, I have found it better, after they have begun to bloom, to use nothing else, but I always apply it in a very weak state, and use it in this way any offensive odour is reduced to a minimum. Referring to manure-water, I have never been able yet to discover the utility of being particular as to the material employed, such as sheep droppings and the like, finding that made from horse manure and guano no way inferior, but in all cases I add some soot to it, which goes far to destroy any disagreeable smell, clarifies the liquid, and is objectionable to insects of every description. To keep down red spider on Fuchsias, as well as on other plants on which it will live, advantage should be taken of the early morning, or any other occasion when it is known that the structure will not be required for promenade, to apply the syringe freely; not a mere sprinkling, such as that given by a thoughtless operator, but a thorough wetting of the under surface of the leaves, where these minute pests as well as thrips are taught by instinct to lodge. With a like object in view, the garden engine should from time to time be brought into requisition, in order to reach the roof climbers thoroughly, bearing

in mind that one good washing is much more effectual than a dozen dewings. This is especially the case with Roses grown in such positions.

Lilies.—Where a good stock of such kinds as *L. eximium* and *L. auratum* that naturally bloom the earliest exist, they will be found very useful for many purposes, particularly the former, which from its less powerful odour may be used in larger numbers than the latter kinds.

Palms.—In addition to the varieties of Palms that succeed altogether in a greenhouse temperature, there are many that through the winter need a cool stove or intermediate house-warmth, which will for the next three months bear conservatory or greenhouse treatment; these, combined with Cycads, Encephalartos, Beaucarneas, Zamias, Dasylirions, Agaves, and Yuccas, the largest used as a background, the smaller and more feathery forms, intermixed with such blooming plants as may be available, will produce a good effect, although not so floriferous as earlier in the season.

Greenhouse.

Hard-wooded Plants.—There would appear to be a general disappearance of many of these beautiful and distinct plants from greenhouses and conservatories. For this the reason often assigned is the formal look which they have when trained, as seen on exhibition stages; but it should be remembered that when wanted for this purpose this is a necessity, and that when the same kinds of plants are only required for home decoration, such training is unnecessary. It is certainly necessary to keep in view the general habit of the plants, and when cultivated in pots in their early stages the principal shoots should be stopped sufficiently often, and the strongest branches tied out in a partially horizontal position towards the rim of the pot; this it is necessary to do, in order to prevent their getting bare and naked of foliage at the base as they get larger, and to counteract the disposition which these, in common with most other plants, have to spire up thinly when grown under glass. Were the numerous family of hard-wooded plants known in cultivation introduced in sufficient numbers to greenhouses and conservatories through the spring, and especially the summer and autumn months, for association with the comparatively few flowering subjects that now find favour with cultivators, these structures would not have the appearance that they now too often present, containing as they do little beyond the usual plants grown for effective leafage, intermixed with zonal Pelargoniums, Fuchsias, and the few other blooming plants that go to make up the general display. Amongst the plants that I would suggest for use in this way I should not recommend many of those concerning which there is more than ordinary difficulty as regards culture, either from inability to grow freely or a disposition to die off suddenly, particularly by those who have not had much experience in their growth.

The general stock that has been potted, as recommended through the spring, owing to the absence of sun and the consequent less necessity for the admission of a large amount of external air, will have had a more than usually favourable opportunity for the roots taking to the new soil; let them be placed where they will be fully exposed on all sides to light during the time when growth is being made, for both wood and foliage will be comparatively weak and soft. It is well to remember that the growing season this year, through the absence of genial spring weather, which, to a great extent, has an influence upon plants cultivated under glass, will be comparatively short, allowing much less than ordinary time for development and maturity; and it will be much better to be satisfied with a less summer's growth than to attempt by any over-excitement to make up for the later condition plants of all descriptions are in this season. This is especially the case with such hard-wooded species as naturally flower late in the spring or summer, and that do not make growth till after the blooming is over, which is quite a month later than usual. Summer-blooming Heaths particularly will be influenced in this way, and many of these will have not more than completed half their usual growth before the time comes for placing them out-of-doors. Concerning the yellow-flowered *E. Cavendishi*, one of the freest growers and most vigorous constitutioned of all Heaths, it is not generally known that it succeeds well with a little extra warmth whilst making its growth for some six weeks after blooming, treatment that would be fatal to the health of most Heaths; but if the flowers, immediately on their fading, be picked off, and the plants placed amongst growing Azaleas, where extra warmth is kept up by early closing the house and syringing the plants freely at the same time, as is the custom in the case of Azaleas, this Heath may be induced to make sufficient growth, and still have time for fully ripening the wood in a way that will induce it to flower satisfactorily every year, a result not attainable more than each alternate season under the ordinary system of management.

Cutting Back Heath.—The freer growing kinds of Heaths, such as the plant just noticed, *E. affinis*, *E. ferruginea*, *E. Hartnelli*, *E. propendens*, most of the *ventricosas*, and others of similar habit, when they have been allowed to get too tall will bear shortening to one-third or one-half their size; and if the roots are abundant and in good condition, they will grow away freely afterwards, and by this means the lower portion of the plant will gradually become furnished with young shoots; but, as a matter of course, plants so treated must be kept in pits or houses for some time afterwards, and there should be no attempt to disturb their roots by potting however much they may be in want of this until autumn; all the freer-growing description will not only bear, but be considerably assisted by the use of weak clear manure water during the time they are making growth. I mention this, as I often find there is an impression that Heaths will not stand any liquid stimulant, which is a mistake; yet it may be necessary to caution the inexperienced that these, in common with all slow-growing subjects, will not bear its use in anything near so strong a state as grosser, quicker-growing plants, and it never should be given them, excepting after they have commenced shoot growth and during the time of its extension.

Chrysanthemums.—The time of putting these plants into the pots they will bloom in will, as a matter of course, be regulated by the time at which they were struck; such as grown from cuttings put in about the close of the year, and which will produce a greater profusion of fully-developed flowers than the later struck ones, will, as already advised, be ere this in their blooming pots, and all the later propagated ones should at once have their last shift, for if kept confined in little pots too long the certain consequence is the loss of the lower leaves and a hardened condition of the shoots, both of which it is not possible afterwards to set to rights. Leaf mould as a mixture with the soil is sometimes recommended for Chrysanthemums, but I have always found them when this has been employed have a greater disposition to make shoot growth than to flower freely. Good turfy loam, with a moderate addition of sifted rotten manure and sufficient sand, will grow them well, potting more firmly than they are sometimes treated to. As soon as they have got fairly hold of the soil stop the shoots so far as necessary, but not more, as this pinching is frequently carried much too far and resorted to too late, in which case it interferes with the blooming.—T. BAIXES.

Hardy Fruit.

Any trees that are fruiting freely and which, on account of others being thin of fruit, must carry a heavy crop, should have assistance either in the way of manure water or, what would be better, considering this wet season, rich surface mulchings, or an occasional sprinkling of guano. From long observation, I have come to regard the application of such stimulants as doubly valuable when applied early in the season. As soon as the fruit has formed and is starting to swell is when they are most effective; after that period they are comparatively valueless—at all events as far as the present season's fruit is concerned. Judging by recent accounts, Pears generally are likely to be thin; though the bloom was profuse and apparently set well, the greater part has since fallen, owing to the long continued dull wet weather. At this place Pears on walls are bearing a full crop, and there is a fair crop on standards, though many which were most promising a few weeks ago are now very thin, indeed, and the prolific trees will have to make up for the loss, aided as has just been indicated. The remarks lately made as to the extermination of aphides are still necessary, Cherries being more violently attacked than I have known them to be for some years. Pears and Plums on walls now need to have all the breastwood cut back to within two, or at most three, joints of the old wood; but previously select all new growths that are to be laid in as permanent branches, and tie, nail, or fasten them back temporarily with small sticks; then remove all the strongest-growing shoots from every part of the tree, and complete the operation at an interval of a week, thus avoiding the check that must necessarily ensue were all cut off at once. Finish thinning out any clusters of fruit requiring it, and let all wall trees be washed with clear water to dislodge the fallen blossoms and cobwebs. The common spider is on too friendly terms with his relative the red spider to be allowed undisturbed possession of warm dry corners. What I mean is, that an attack of red spider is sometimes superinduced by the presence of ordinary cobwebs, which I have seen covered with red spider; therefore no quarter should be given to either of these pests. Strawberries are likely to be a heavy crop, and no time should be lost in keeping the fruit off the soil by a thin layer of straw; this we never require to do, our practice being to give a thick mulching of fresh stable litter early in May, and this by the time the fruit needs protection is washed clean by the rains. All varieties have grown so vigorously that small twigs to support the clusters of fruit will be almost a necessity, and certainly of immense service against the ravages of

slugs, which are very numerous, notwithstanding the late severe winter. Unless the predicted hot weather comes very soon, Vines in the open air will probably be a failure; for they are even now barely ready for stopping or pinching out the points in front of the "shows"; still, the same care should be exercised in their culture as if fruit prospects were ever so cheering. Disbud, stop, and train in new growth where such is required, as in the case of indoor Vines young canes produce the finest fruit, and provision should be made for the renewal of old ones, by occasionally training in new shoots to take their place at the winter pruning. The season will also be a short one for Figs, and the fruit will require all the aid that can be afforded in order to enable it to mature, such as exposure to full light and sunshine, by tying aside the leaves, and stopping all growth at the third or fourth joint, except those that are required to cover the wall. Such constant stopping not only represses growth and induces fruitfulness, but aids materially the swelling of the fruit. Loosen or untie altogether as may be requisite the ligatures of grafts; as a rule, it will be safe to dispense with ties altogether, and the only attention now requisite will be to keep the stock free from shoots and suckers; these latter should be persistently removed from all fruit trees; this season they are more than usually numerous, owing no doubt to the excessive rainfall.—IV. W.

TREES, SHRUBS, AND WOODLANDS.

STREET TREES.

THE very unpropitious weather experienced during the first five months of the present year, coupled with the extreme backwardness of the season, has not been all that could be desired for the well-being of newly planted trees in streets, and unless a favourable change follows, the wood now being made will not be sufficiently matured to withstand the influence of a severe and lengthened winter should such occur. I do not say the trees will die, but they will be less vigorous than under more genial circumstances. Of all trees connected with the beautifying of towns, so far as the horticulturist is concerned, none requires more care and tact than street planting, in order that the result may be successful. The materials with which roadways are usually made being not only of bad quality for the purpose of planting, but often positively destructive to vegetation, it is perfectly useless in such cases to look for that healthy and vigorous growth so essential in street trees, unless they are planted in soil both suitable as regards quality and quantity. With regard to the selection of trees for towns, very little difference of opinion exists among those whose practical and lengthened experience render them most competent to give an opinion. The Plane is the kind generally planted, and very justly too, as few trees can bear comparison with it for beauty, vigour, durability, and smoke-resisting properties; it is, in fact, without doubt *par excellence* specially adapted for town planting. The Horse Chestnut planted alternately with Planes in some districts is, in my opinion, a great mistake. Why is it that we do not often see Poplars planted? there are many varieties of them, and most of them possess the characteristics which are necessary in a town tree. The Black Italian, for instance, produces dense foliage not liable to become prematurely affected by heat and dust, as is the case with Limes, Chestnuts, &c.; it is handsome in outline, and unsurpassed for vigorous growth. I am confident that for planting alternately with Planes no trees are more suitable, and planted alone as avenues, it would give greater satisfaction than many trees which are used for that purpose.

One evident source of failure in planting street trees is, in my opinion, the pent-up condition of the roots. In the majority of cases those who plant seem to think that it is sufficient to cut a small circular hole in the pavement just large enough to admit the roots to pass and to fix the guard. This is a great mistake, ultimately resulting in injury to the trees or killing them outright. Many large and well-established trees could be pointed out which have died in consequence of having the paving brought up close to their stems. The roots should have ample breathing-room, for which purpose the surface of the soil should be covered by gratings or encircled by tree guards; this not only allows of sufficient water being given when necessary, but also prevents the accumulation of deleterious gases beneath the pavement in dangerous proximity to the roots, and affords facilities for keeping the surface-soil in an open and healthy condition. Newly-planted trees should, in my opinion, be firmly staked to prevent the roots from being loosened in the soil; this is generally most carelessly done; in many instances no supports are placed to the trees, in others simply a collar is fixed to prevent injury by rubbing against the guards. As a consequence, some trees will be found to lean in the direction of the roadway, others towards the houses—effectually destroying the most desirable

results aimed at in planting avenues, namely, symmetry and regularity.

These matters though simple are so important, that no one planting street trees should neglect them. They add but little to the cost whilst the advantage gained is very great. Certainly it is far better to have twenty good trees than a hundred miserable ones. Let anyone examine the trees upon the Victoria Embankment, where the foregoing conditions have been rigidly observed, and ask himself whether the work has not been well repaid. There is no valid reason why success in other districts should not be achieved provided the same means are adopted. Fortunately the majority of the trees in this truly noble avenue are now able to support themselves without artificial aid, and it has therefore been wisely resolved not to subject them to the severe pruning rendered necessary during the past few years. The appearance of the trees as a consequence is much improved, and they now bid fair to assume those natural proportions so much admired in well-grown Planes.

Southwark Park.

CHARLES DENNIS.

FERTILISATION OF THE ARAUCARIA.

In the "Revue Horticole" for 1878 (p. 443) an account was given of the experiments made by M. Hauguel on the fertilisation of certain specimens of the *Araucaria imbricata* in the department of the

members of the same genus ; for instance, amongst the Pines, while all those belonging to the *Strobus* section open in the autumn, or even at the end of the summer of the second year, it is not a rare occurrence amongst those belonging to the *Pinaster* and the *Pseudostrobus* section to see their ligneous cones remaining on the tree for an indefinite period. From these facts it results that the epithets "annual and biennial maturity" are misnomers, generally speaking, and can only be applied in a very few cases. If, instead of taking into account the duration of fruit on the tree, we confine ourselves to taking account of the time which elapses between the fecundation and the ripening of the seed, we shall find ourselves almost inclined to think that the whole of these species are annual.

What has hitherto deceived most observers is that there are many species in which the cones do not reach the adult stage until long after they have made their appearance on the tree ; there is, however, an easy method of determining the arrival of this period by watching for the dissemination of the pollen. As shown in the figure, the male catkins of the *Araucaria imbricata* make their appearance early in the spring ; the pollen, which is very abundant, escaping in the month of June, at the period when the cones, which by that time have gained a considerable size, open their scales and expose the ovules, which thus become impregnated with pollen. From this epoch, three months are sufficient for the seed to become ripe and fit for reproduction. Amongst purely annual plants we may mention those of the *Abies*, the *Yew*, and the *Ginkgos*. E. A. CARRIERE.

Male catkins of the *Araucaria imbricata* (one-quarter of their natural size).

Seine-Inferieure, which gives ample information as to the time which is necessary for the seeds of these trees to become perfectly ripe, starting from the day of fertilisation. It was then stated that in the case of *Araucaria imbricata* the period was three months. All the treatises which speak of this species state, with regard to its fruit, that its maturation is biennial. These two statements, which are apparently at variance with each other, apply equally to most of the genera of the Conifers, if not to all of them. The difference between them has struck several of our readers, some of whom having written to us on the subject, we only think it right to give a few explanations on the matter. These explanations are all the more necessary, seeing that there is an important point connected with the question which has hitherto been too much neglected from a practical point of view. The difference in these statements simply arises from confounding together two very different things, that is to say, the fecundation of the fruit with the duration of its persistence on the tree. In any case, it is totally illogical to say annual or biennial maturity, because some of the cones do not remain on the tree even for a year, while others hang on their native twigs for four, eight, fifteen years, and even more. Thus, while the fruit of the *Yew*, the *Cephalotaxus*, and the *Abies*, fall as soon as they come to maturity, and those of the *Tsuga*, the *Biota*, and the *Cedar* fall at an interval of from fifteen months to three years, there are others which resist the tendency to fall almost for an indefinite period, such as the *Cypress* and the *Frenela*. We also find a great difference in the

RHODODENDRONS.

ALTHOUGH the wet, sunless weather which we have had up to the middle of June has been anything but favourable for most plants, *Rhododendrons* have benefited greatly by it, the cool, moist state of the atmosphere admitting of a gradual swelling of the buds, which have now opened most satisfactorily. Seeing that *Rhododendrons* will grow nearly as freely as *Laurels*, and that they are even harder, the wonder is that they are not planted to a greater extent than they are, for besides the magnificent trusses of bloom which they bear, they are equal to any evergreen as a blind, or for ornamental purposes in pleasure grounds, where, if judiciously grouped and backed up with *Hollies*, so as to ward off strong winds when in flower, they may be made to form quite a feature. I know that many entertain a notion that *Rhododendrons* will not succeed without peat, but that is a mistake, for there are some soils in which they do quite as well or even better than in peat, provided they can get moisture enough. A friable loam containing a good deal of sharp grit suits them admirably if it is fresh and has not been under cultivation, and if they can have this and a moderate amount of shade they will flourish anywhere, except in places where there is calcareous matter. This they dislike, and therefore where chalk abounds it is useless attempting their cultivation, unless special preparations are made before planting by excavating large holes, and filling them with soil more congenial to them. As their roots do not spread much, they only require a moderate depth in which to grow, but a mistake into which many fall in filling beds is having them too high, thereby thinking to produce an immediate effect, instead of which the plants, under such circumstances, are incapable of making any progress and dwindle away and die. Rather than have the surface above the general level it should be below it, as then they get the benefit of what rain falls, whereas where the beds are elevated it is mostly lost from draining off to the sides, where it soaks in out of their reach. Some few years ago a collection of *Rhododendrons* was nearly killed through having been planted in this manner, but after being lowered the plants quite recovered, and are now as healthy and floriferous as it is possible for *Rhododendrons* to be. The soil in which these are growing looked more like gravel than anything else, so full is it of small stones and sand ; and yet in this where many would hardly expect a *Laurel* to succeed *Rhododendrons* are found to luxuriate. True, they do not make quite so much wood as they often do in peat, but that is an advantage, except in cases where it is desired to get them to a large size quickly, as they grow more compact and always set a great quantity of buds.

Parings and trimmings from roadsides answer capitally for *Rhododendrons*, and if to this is added about half its bulk of thoroughly decomposed leaf-mould, no mixture or soil that can be got will suit them better. Where only single plants are wanted, it is a good plan to dig holes that will each hold about a couple of barrowloads of this material, to which, unless the surrounding ground be congenial, the roots will confine themselves and form a compact ball that after a time may be lifted entire. I once had some seedlings planted out in a quarter of the garden in narrow trenches which had been prepared for them ; these plants could be pulled up holding together in one long string, and they had to be chopped through in order to separate them—a fact which shows how much they confine themselves to any particular soil which they like, and how they avoid any

that has been long under cultivation. What there is in this they object to I know not, but certain it is they are never found to thrive in it, and yet they are fond of manure when used as a mulching, in which way it answers the double purpose of acting as a stimulant and keeping the ground shaded and the roots cool and moist. This is half the battle in growing *Rhododendrons*, for if they suffer at this time of year from want of water, the young shoots are checked in their progress and become so stunted as to be unable to set their flower-buds. Although *Rhododendrons* are naturally moisture-loving subjects, a wet, stagnant condition of the soil soon throws them out of health, yet they are just at home by the sides of running streams or in positions where water can drain freely away from them. As an under shrub in game covers, the common *R. ponticum* is unsurpassed, as neither rabbits nor hares will touch it, however short of food they may be, and, being of a spreading habit, it just suits pheasants to hide under. Fallen leaves in a state of decay that always abound in woods make the surface-soil exactly suited to the wants of *Rhododendrons*, and *R. ponticum* being less particular than choicer varieties may be planted with certainty of success even without such vegetable deposits. S. D.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Laurels in Kensington Gardens.—We notice with pleasure that a great number of Laurels have been cleared away from under the group of varied Ash trees in Kensington Gardens. A great deal of harm is often done in such cases by useless and monotonous underwood, which crowds and robs the trees that one really wants to develop, and is in itself, especially in a public park, of no use whatever. Kensington Gardens should always be as they are now—the home of fine trees, and everything which interferes with their freedom and health should be removed.

Some New, or Little-known Willows.—Dr. Carl Bolle ("Berliner Monatschrift") directs attention to the merits of *Salix ulralensis*, *S. rosmarinifolia*, and *S. rigida pendula*. The last he states is a noble and handsome novelty, and a valuable addition to our choice of Weeping Willows. It was accidentally discovered amongst a number of cuttings of typical *S. rigida*, creeping along on the ground instead of growing erect, and the happy finder, Mr. Joseph Wrede, lost no time in grafting it on stems of *Salix pyramidalis*. This happened four or five years ago, and the results have exceeded expectations, the new Weeping Willow being only of moderately strong growth, and therefore suitable for small gardens. *S. rosmarinifolia* is of course better known; but, as Mr. Bolle observes, it is much rarer than it ought to be. It certainly is one of the handsomest, if not the handsomest, species of a genus rich in beautiful forms. Its proper name is *S. incana*. *S. ulralensis* is described as a very useful Willow on account of the pliability and toughness of its slender branches, which are suitable for the finest basket-work. Professor Koch refers to this in his "Dendrologie" as a variety of *S. helix*.—"Gardeners' Chronicle."

Rabbit-proof Trees.—I was much surprised to see the *Laburnum* mentioned by "M. C. D." (p. 416) as a tree that was rabbit-proof or nearly so. In a well-known botanical work it is stated that hares and rabbits are so "extremely fond of the *Laburnum* bark, that they will eat no other tree so long as they can get a supply of it." I would not say that they will leave everything else for it, but my experience is that they are extremely fond of the *Laburnum*, and I believe it is sometimes planted or sown extensively in woods for the very purpose of diverting rabbits from other trees. I think they are, next to the *Laburnum*, fondest of Hollies, young plantations of which they destroy wholesale. On one estate, where a nurseryman had planted the different varieties of Hollies upon an extensive scale on the ornamental "massing system," the rabbits which swarmed in the park had not been reckoned upon, and in one year they nearly ruined every plant. *Cupressus Lawsoniana* is eaten up by them here during hard winters as far as they can reach. —J. S. W.

The Late Dr. Moore.—We omitted last week to mention that a portrait of Dr. Moore was given in *THE GARDEN* (Vol. XIII.). The following concerning him is taken from the "Irish Farmer's Gazette":—"On the present occasion we have neither the spirits nor the inclination to allude to Dr. Moore's long and useful public career. Sorrow for loss of a long known and greatly valued friend, and sincerest sympathy for his family in their sore bereavement, forbid any effort in that direction. We cannot, however, conclude without expressing a hope that the heads of the Department of Science and Art may see their way to selecting as his successor his eldest son, Mr. F. Moore, the present Curator of our University Botanic Garden. The appointment would be a popular one."

The Late H. Noel Humphreys.—In "The Times" of Saturday we briefly recorded the decease of a distinguished naturalist and archaeologist, Mr. Henry Noel Humphreys, which occurred at the close of last week at his residence in Westbourne Square, Hyde Park. A son of the late Mr. James Humphreys, of Birmingham, he was born in the Midland metropolis in 1809 or of the following year, and received his early education at King Edward's School, Birmingham. Having spent some time in artistic studies in Italy, he published his first work, consisting of illustrations of Mr. W. B. Cooke's scenery of Rome and its neighbourhood. His next work, which bears date 1840, entitled "British Butterflies and their Transformations," was published in partnership with Mr. J. O. Westwood. This was followed by a similar work on "British Moths," three years subsequently. Among his most important works of an archaeological character between this date and 1856 may be specified "Illustrations of Froissart's Chronicles," "The Parables of Our Lord Illustrated," "The Coins of England," "Ancient Coins and Medals," "The Illuminated Books of the Mediæval Period," the "Coin Collector's Manual," the "Coinage of the British Empire," "Stories by an Archaeologist," and especially his *magna opera*, so to speak, "The Art of Illumination," and "The History of the Art of Writing from the Hieroglyphic Period down to the Introduction of Alphabets." Mr. Humphreys has contributed to lighter literature at all events one dramatic novelette, called "Goethe in Strasbourg," and he was a frequent contributor to the "Gentleman's Magazine," and to "Once a Week" in its palmy days, on subjects connected with his zoological and antiquarian researches.—"Times," June 16.

ANSWERS TO CORRESPONDENTS.

Culture of the Azorean Forget-me-not.—I should be glad to know what is the proper treatment of *Myosotis azorica* so as to induce it to flower freely. Some plants which were sown in July last are still without flowers. Is it a summer or permanent plant? (This species is a perennial, though during severe winters it is frequently destroyed when unprotected out-of-doors. It succeeds best in rather shaded situations, and delights in a moist rich soil, where it flowers freely and continuously throughout the summer, and if the plants in question are treated about as I doubt they will thrive. If grown in a dry border it is subject to attacks of mildew, which prevents it from flowering, and ultimately kills it.—W. G.)

Tall Peas.—I sowed Wheeler's First Early Peas in pots the first week in January, and planted them out in the end of February on a west wall border, and at the present time they are 7 ft. high and one mass of bloom. They look, too, as if they were capable of growing another 2 ft. or 3 ft. Nothing was dug in the ground except a small quantity of rotten stable manure, but the soil largely consists of town sweepings. Wheeler's First Early is reported to grow 2 ft.—R. G. [Peas everywhere have grown unusually tall this year, so much so in many places as to need toping.]

Pear Tree Insects.—*D. S.*—Not red spider, which belongs to the mite family, but a scale blight or cocoon, in that state where the dead bodies of the females are covering a multitude of eggs, some of which are just hatching. Let the scale be destroyed as soon as possible by washing the branches with a strong mixture of soft soap and soot.—W. W. S.

Black Spot on Peas.—I am very much troubled with a little black spot on my Peas; the sort has very little to do with it. By-and-by, as the fruits enlarge, so do the spots, and then cracks come on the surface and decay begins. Is it a fungus, and will sulphur stop it? What is the cause of it?—JOHN MARTEN, *Chilham*. (The black spot on the Peas sort is due to the presence of a dusky fungus named *Cladosporium dendriticum* (commonly quoted as *Helminthosporium peronospora*). The cracks on the fruit as mentioned are said to be caused by the presence of the fungus. We know no cure.)

Seedling Aquilegia.—*F. M. E.*—The specimen sent is certainly handsome and the colours distinct, but it too nearly resembles the hybrids that are raised by crossing *A. vulgaris* and *A. chrysantha*, and which are now becoming common in collections to be suitable for the purpose you suggest.

Rhododendron Hardyannum.—In reference to my question (p. 488) I may state that I have both *R. Hardyannum* and *Blandyanum*. The flower of *Hardyannum* is nearly the same as that of *R. Blandyanum*, but a shade lighter crimson. The leaf of *Hardyannum* is smaller and very distinct.—W. A. SMITH, *Broughton Bank, Manchester*.

Names of Plants.—*W. A. S.*—1, *Coccoloba pterocarpa*; 2, plants cannot be named with certainty from leaves only. *C. M.*—*Paulownia imperialis*. *T. P.*—Apparently *Medicago maculata*; send Orchids when in flower. *C.*—*Chrysanthemum frutescens*. *St. L. B.*—Some *Philadelphus*. *M. C.*—Apparently *Magnolia Lenzii*. *C. E. O.*—*Odontoglossum maculatum*. *C. J. L.*—*Staphylea pinnatifida*. *H. M.*—*Med.*—5, *Echiochorda grandiflora*; 6, *Centaurea montana*; 7, *Hieracium aurantiacum*; others next week. *G. T.*—1, *Saxifraga hypnoides* var.; 2, *Sedum album*; 3, *S. reflexum*; 4, *S. Selskianum*. *Cottager*.—*Philadelphus coronarius*.

Diseased Grapes.—There is no cankerous growth in the Grapes sent; the cuticle is somewhat cracked and discoloured, but beyond that we do not think the berries are affected.

Questions.

Tuberose.—Kindly give me a little advice about these. I procured my bulbs in September; since then they have been standing in a temperature of 75° (say Vintry), planted three in a pot. They are not coming to thrive, and are much infested with green fly. What am I to do?—M. J. F.

Conservatory Beds.—I am building a conservatory 55 ft. long and 30 ft. wide with an entrance porch 15 ft. square. I have three Camellias to plant in it, each 10 ft. high and 10 ft. in diameter; I dislike the plan of a square bed in centre for them. Would some of your correspondents kindly give advice as to the internal arrangement of the space, with ideas of how it may be broken up into beds for flowers or Ferns?—BALLATH BURY.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES ON SPANISH NARCISSI.

DURING the latter part of April and early part of May, in company with the Rev. H. H. Crewe, I made a botanical tour through Spain and Minorca, and as we met with many species of Narcissi, I think a few notes on their distribution may be acceptable to the readers of THE GARDEN.

We entered Spain by way of Bordeaux and Biarritz. Our first Narcissus was a large sulphur-coloured Corbularia, observed by the side of the railway between Dax and Bayonne in passing through the Pine forests of the Landes. This is probably the most northern point to which the genus Corbularia reaches. In the neighbourhood of Biarritz the same form is still more abundant, being widely distributed as isolated patches in the moist heathy hollows; it is probably a variety of the old garden Corbularia Bulbocodium, though much paler in colour. The variation both in size and colour of the Corbularias met with in the north and centre of Spain was most perplexing, and raised the doubt as to the extent to which separate specific rank should be assigned. The extreme forms, both as regards colour and size, were apparently most distinct, but the intermediate gradations so numerous and ill-defined that in the majority of cases we dared not assign a specific name. The variations, however, were not gradually intermixed, and, as a rule, where two forms were associated, they were not those most nearly allied and not intermingled, but occurring as separate patches. Mr. Llewellyn informs me that the Biarritz sulphur-coloured form occurs also in great abundance about Bagnères de Bigorre, in the Pyrenees, and we again found it abundantly on the hills to the north-west of Pancorbo, at a height of from 2500 ft. to 3000 ft. It was slightly smaller and darker than the Biarritz plant, but still much paler than the Corbularia Bulbocodium of gardens.

At Pancorbo we also found a lovely little Narcissus which we could not distinguish from *N. minimus* of gardens. A night journey from Pancorbo to Palencia precluded observations in the intermediate district, but midway between Palencia and Leon the moist meadows were golden-yellow with a small orange Corbularia, and this extended for fully forty miles with scarcely an interruption to the village of Busdongo, near the Puerto de Pajares, the pass over the Asturias, ranging from a height of 2500 feet to nearly 4000 feet above the sea. We observed no other Narcissus in the northern descent of the Asturias till we approached the bottom of the pass, where, about six miles to the north of Pola de Lena, the rocks above the road were adorned with a pale cream-coloured Narcissus, one of the numerous forms of *N. triandrus*, probably *N. calathinus*. This appeared at short intervals in some neighbouring localities. North of Oviedo the moist meadows by the side of the railway were bright with a large, pale straw-coloured Corbularia, somewhat paler than the Biarritz form, but scarcely distinct enough to separate as a species.

The golden-yellow form, so abundant and continuous on the north side of the Asturias, was here absent, but in a meadow near Gijon, on the coast, we found two or three specimens agreeing with it in colour, but exceptionally large; in the same meadow *Narcissus biflorus* was abundant. The pale *Narcissus triandrus* (? *calathinus*) was again abundant

in the neighbourhood of Gijon, and was observed in several localities on dry rocks near Varina, west of the town. Cultivators should bear in mind that *Narcissus triandrus* and its allies like dry, rocky locations, whilst the Corbularia almost invariably occur in wet places—so wet where we found them in the north of Spain, that they were troublesome to dig up, bespattering the collector with mud.

From Leon to the northern slopes of the Sierra de Guadarrama our journey was by night. We passed Avila in the early morning, and soon after crossing the watershed of the Guadarrama, at a height of about 4400 feet, separating the basins of the Douro and the Tagus, the Alpine meadows near the station of Naval Grande were speckled with the tiny yellow Corbularia nivalis; this also occurred at intervals between Naval Grande and Naval Peral; but at the latter place it was larger than the typical form, and was here and there intermixed with a large form which differs little from the old Corbularia Bulbocodium in cultivation.

At Naval Peral a pale straw-coloured Corbularia (probably *C. Graelsi*) set in, occurring as separate patches and on rather dryer ground than *C. nivalis*, and continued at intervals all the way to El Escorial, and in moist meadows south of El Escorial, half way to Madrid. The specimens we obtained were somewhat darker in colour than those received from Professor Graels in 1876.

On dry rocks between Naval Peral and El Escorial the beautiful *Narcissus pallidulus* (a pale variety of *Narcissus triandrus*) commenced and continued at intervals along the line half way from El Escorial to Madrid; we also found it abundantly above El Escorial, up to an altitude of 3500 ft.

Narcissus rupicola, allied to *N. juncifolius*, was extremely abundant about the lowest projecting rocks north-west of El Escorial. I also obtained it sparingly in 1871 in the neighbouring Sierra d'Avila, at a height of between 4000 ft. and 5000 ft., but it does not appear to be so widely distributed in this region as the Corbularias and *Narcissus pallidulus*, which are so extremely abundant, as to form one of the most conspicuous floral features of the district.

South of Madrid we observed no more Narcissi till we reached the island of Minorca, where we obtained *Narcissus serotinus* in leaf. This also occurs abundantly in Majorca, where I found it in flower in October, 1876. We observed also in Minorca, rather plentifully, a variety of *Narcissus Tazetta*, just out of flower, which is said to differ from the typical form.

GEORGE MAW, F.L.S.

Violas and Pansies.—All the so-called Violas now grown for bedding purposes are garden hybrids, and may be called Violas or Pansies just as it suits the taste of the grower. Practically there is little or nothing left now to distinguish the bedding Viola from the bedding Pansy, and although anyone well acquainted with the different kinds could probably distinguish them, it would be exceedingly difficult to make their differences apparent in print. To prevent further misapprehension and mistakes in the future, I think it would be wise to distinguish all bedding kinds as bedding Pansies, leaving the term Viola to be applied solely to species such as *cornuta*, *lutea*, *stricta*, &c. That most if not all of the largest flowered kinds of these Violas have been bred from contact with Pansies there can be little doubt. I know that my first break from Perfection was produced in that way, and it is most probable that insects have done much as regards crossing. We have show or English Pansies, fancy or Belgian Pansies, and a class of bedding Pansies would include all others worth naming. As to the award at the Manchester show, it was evident that bedding kinds only should have been invited, and then the judges should have decided upon their merits just as the plants presented suitable bedding features; but as in this class Mr. Hooper was the only exhibitor, there was nothing over which to raise discussion. In reality all these things can only be judged when planted out in quantity, and then it is rarely that large flowered kinds prove the most effective. A dwarf, spreading habit,

medium-sized flowers of some good colour produced in great abundance and for a long period, are the best characteristics of a bedding Pansy.—A. D.

—Mr. Williams (p. 493) is mistaken when he states, that *Viola* *The Tory* was bred from a Pansy, i.e., *Viola* tricolor. Its seed parent was *V. cornuta* Perfection, as which was also that of Alpha, Advancer, rubra-lilacina, and White Perfection. I fear "Brookhurst's" suggestion (p. 493) will not answer if the eye is to be his only guide. I have a number of varieties raised from *V. stricta* without even a single line or ray from the eye.—JAMES GRIEVE, *Pilrig Cottage, Pilrig Street, Edinburgh*.

Sempervivums.—In the account of the rockery at St. Alban's Court (p. 492) a Sempervivum is described as a "variety of arachnoideum, with a good deal of red on the rosettes." This is doubtless S. Pomelli, a very handsome species, distinguished from arachnoideum by having the tuft of wool at the point of each leaf distinct and not co-mingled as in the latter. As may be expected, there is much confusion among the Sempervivums.—THOS. WILLIAMS, *Ormskirck*.

Hotela japonica for Edging Beds.—This useful plant, so largely grown for forcing, makes a beautiful permanent edging for large beds, its foliage being so ornamental, that even without its feathery spikes of white flowers it is effective and fresh looking. We have at present hundreds of clumps of this plant, all of which appear to enjoy the abundance of moisture we are experiencing this season.—J. GROOM, *Linton Park, Maidstone*.

Gigantic Poppies.—Mr. Stevens' Poppies, noticed in THE GARDEN (p. 497), are, doubtless, what are known and sold as *Papaver involucreum maximum*. This has enormous flowers, a clump of which may be seen a mile off. It will grow anywhere. I have in view now a plant, with about thirty of its enormous buds ready to open. This plant is confounded with *P. bracteatum*, a flower with a deep crimson colour, having a solitary bract just under the bloom.—THOS. WILLIAMS, *Ormskirck*.

Myosotis Weirleigh Surprise.—This is the name of the blue and white striped Forget-me-not which your correspondent saw at Mr. Cannell's (p. 496). We have a good deal of it here, and exhibited a large pan of it amongst our plants at the Manchester show, where it was much admired. It is, I believe, a sport from *M. alpestris*, and grows as freely and flowers as profusely as that variety. It is very beautiful, especially for bouquets. I am told that it does not come true from seed, but it is easily propagated by division and cuttings.—BROCKHURST.

Aquilegia chrysantha.—This plant's liking for a moist spot has been clearly shown this season. A strong specimen of it planted along with a number of similar plants in a waterside bed, the surface of which is only about 4 in. higher than the level of the water, is now in the most vigorous health. It has thrown up about twenty stems, and its flowers, notwithstanding the very backward character of the season generally, are now just on the point of opening; while a number of smaller plants on a warm and drier spot have all, with one or two exceptions, been killed by the winter frost.—T. SMITH, *Newry*.

Tropæolums in Plant Baskets.—We have a good many flower beds made in the form of baskets, their outer edges and handles being clothed with Ivy. I find Tropæolums very effective trained over the handles and allowed to mingle with the Ivy. Having a quantity of very tall scarlet Tropæolums, we planted them early under the shelter of the Ivy, and they now form most brilliant and striking masses of colour. I may add that these Ivy baskets, well filled with brilliant-flowered plants, the edge being fringed with trailers, make pretty objects in the flower garden.—J. GROOM, *Linton Park, Maidstone*.

Phormium tenax.—A large specimen of this, planted near water, though quite killed to the ground, is now shooting up strongly again, and some of the first leaves are already 2 ft. high. On the other hand, a small plant of the variegated New Zealand Flax planted near the one just alluded to, but on a little mound raised about 1 ft. above the water, and which had not its leaves killed, is only just showing signs of new growth. Let us hope that the above may be the present condition of many of the plants reported to be killed. I should add that I saw a few days ago a strong specimen of the green-leaved sort, which has been growing for several years in the forecourt of some schools at Dundalk—a bleak spot in which scarcely any shrub or tree will thrive—quite uninjured by the frost in any way.—T. SMITH, *Newry*.

Watering Bedding Plants.—At this season, when every owner of a garden is having more or less planting done, it is by no means uncommon to find much unnecessary labour bestowed on watering. Of course in the case of very small plants that have been

shaken out or much disturbed in removal, watering is absolutely necessary, in order to keep the soil sufficiently moist to prevent their drying up before their roots get established, but as long as they will hold up or keep from flagging they root much quicker if kept free from the chilling influence of doses of cold water. During the late exceptionally wet period I have observed that plants in beds and borders that are overshadowed and partly impoverished by the roots of large trees, and therefore the first to suffer in periods of drought, have this season made far more progress than those in open and usually more favourably situated beds, simply because the latter have been saturated and chilled with heavy rains.—J. GROOM.

Evening Primroses in the Wild Garden.—The annexed illustration is an attempt to show the right effect of a colony of the large Evening Primrose naturalised on the margin of a wood. These noble and delicately-scented flowers are very easily grown and very beautiful in any position. They, however, from their height and boldness, and the freedom with which they grow in almost any soil, are peculiarly suited for the wild garden, for shrubberies, copses, and the like, sowing themselves freely. In this case they are apt to become eventually somewhat too numerous and somewhat "starved," so that where confined to large groups in good ground they are best. In any flower garden not confined to flat beds only, a small isolated bed of these *Oenotheras* looks well. Such may be seen in the Emperor of Austria's garden at Laxenburg—this being a favourite flower there. It tells very well in the evenings in these beds—4 ft. wide—on the turf, near the margin of a shrubbery, or near groups of specimens on the Grass.—V.

VEGETABLE CULTURE FOR MARKET.

CUCUMBERS IN PITS AND FRAMES.—During summer the long ranges of pits and frames in market gardens devoted to winter to the protection of tender culinary plants are applied to Cucumber culture, and from these are cut thousands of fruits weekly. Indeed, few frame crops pay better than Cucumbers where they succeed well, and therefore every frame that can possibly be spared is planted with them. One grower at Fulham has a field of frame-ground, containing many ranges of frames with from 800 to 1000 ordinary sashes, in summer entirely devoted to Cucumbers. From this field are sent to market weekly during the summer from 200 to 220 dozen fruits. The Telegraph, and varieties of it, are much grown in frames; so is the Syon House, Pettie's, Rabley, Duke of Edinburgh, Sutton's Perfection, and a few others. Two or three men are usually kept at work in these frame grounds, and on three days of the week (Monday, Wednesday, and Friday) they are employed in cutting fruits for market, and on the other three week-days they are busy stopping and regulating the shoots of the Cucumbers, watering, &c. Should any young fruits exhibit a tendency to become crooked, they put them into cylindrical glasses open at both ends. These glasses are about 12 in. or 15 in. long, and 1½ in. or 2 in. in diameter, and several thousands of them are employed in one large frame-ground, as one good and straight Cucumber is worth nearly a dozen small and deformed ones. The crooked ones are disposed of for pickling. Should any "nosed" fruits, as they are termed, or such as have swelled at the point, be found, which occurs late in the season, a piece of string is tied round them, and they are left to ripen, as such fruits are certain to contain good seed. When the seed fruits become yellow and are cut, they are placed under sashes or on boards exposed to the sun, so as to get thoroughly ripe and hard before being separated from the pulp. The first sowing to supply plants for growing in frames is made in little punnets or flower-pots, early in the year, which are placed in hot manure frames. When the seeds germinate and are fit for potting off, two plants are potted into a 6-in. pot, and the whole replaced in the frames, keeping them near the glass. As soon as the frames to be planted can be spared, they are moved aside, and trenches cast out 5 ft. wide and 2 ft. deep, and firmly filled with stable litter. Over this some soil is placed, and the frames set on again. Another sowing is

generally made to succeed the first one; but, as a rule, there are seldom more than two sowings made, and the second is only sown because all the frames are not empty at one time to be filled by the first sowing. When the heat is at a proper temperature for planting, a little more soil is introduced to the frames, and one potful (containing two plants) is planted under each sash, and one of the plants is trained towards the front of the frame and the other towards the back. The sashes are then put on and all is kept for a few days, and, if need be, a little shading is also given by strewing some litter over the glass.

Afterwards, until the plants have fairly begun to grow, no more ventilation is given than is necessary to prevent scorching in the case of bright sunshine. For several weeks after having been planted they are covered up at night with litter, removing it next morning; indeed, this covering is not discontinued until the month of June. When the plants have grown sufficiently to come into bloom, they are most attentively looked after in the way of regulating the growths, pegging them down, and stopping the lateral shoots at the joint beyond the embryo fruit, and preventing an accumulation of superfluous growths. Throughout the day they are allowed to have plenty of air during the summer, but it is all taken off at night; in the morning the sashes are tilted up a little, and as the heat of the day increases the sashes are still further opened.

Water is given in the morning abundantly to those requiring it, whilst those that are not dry have simply a sprinkling overhead. It is cold water from the tap that is entirely used, and doubtless this is the greatest drawback to Cucurbit growing with which the market gardener has to contend, as where one or several acres are covered with frames, it would be almost an impossibility to make tepid all the water that would be required. Large hogsheads, however, are sunk here and there about the frame-ground, and brick or cement tanks are frequently used for containing water, with which they are filled for the next day's use. Guano-water is sometimes given during the summer time, being applied through a fine rose overhead. This application is not only useful as a stimulant, but when given overhead has been found to be of material benefit in destroying or preventing red spider, as well as

invigorating old plants. In reference to woodlice, toads are put in the frames to destroy them. Cucumbers require sunny weather to set well, and in dull wet seasons they do not thrive well, especially in the earlier part of the year. Should the summer be hot and bright, the sashes are shaded a little, and this is done by strewing some rank litter over the glass; but many market gardeners, by way of economy of labour, paint the sashes with whitening. By August the plants are getting exhausted; therefore careful attention is paid to thinning out old and bare Vines, and encouraging young wood by means

of stimulants, in the way of manure-water and coverings from cold; and in this way they last till September. No fruits are saved for seed until August, for if left sooner they would materially weaken the crop of marketable fruit. Until August Cucumbers are liable to red spider, thrips, green fly, mildew, canker, and various other diseases; the only remedy being that of keeping the plants in as vigorous growth as possible. When mildew attacks the Cucurbit it is generally the result of insufficient ventilation and too low a temperature. When it does appear, dusting thinly but evenly with flour of sulphur through a piece of muslin cloth is the only cure. Thrips are the most terrible of the insect enemies which attack the Cucurbit; for these, and also for green fly, which is sometimes troublesome on the young growths, fumigating with Tobacco is usually resorted to; but the foliage of the Cucurbit is so tender, especially when forced, that fumigation, unless done very carefully, is a cure which is often worse than the disease, and should never be attempted by the inexperienced. For these pests, and also for red spider, it

will generally be found best to apply the "Antidote for Red Spider, Thrips, and Green Fly," by putting a small quantity in the water with which the plants are syringed. This will, if persevered in, obviate the necessity of fumigation, and keep the foliage fresh and green. Canker in the stems may be stopped by filling up the fissures with quicklime.

CUCUMBERS IN THE OPEN AIR.—Market gardeners in the neighbourhood of London grow but few Cucumbers in the open air. Many have attempted it, but most of them have now abandoned it, the result not having proved very satisfactory. Where, however, it is carried on, they are grown

Night effect of Large-flowered Evening Primrose in the Wild Garden.

under glass and hardened off and planted out 6 ft. asunder and 10 ft. row from row, and hand-glasses are put over them. When they begin to grow the ground is well mulched with straw, to keep the earth moist and the fruit clean. Due attention is paid to their after-culture in the way of stopping, thinning, &c., and in some cases fairly good results are obtained. Under any circumstances Cucumbers form an uncertain crop in open fields; but while their produce is in such demand in all large towns, their culture, where they will succeed with tolerable certainty, will no doubt still be largely carried on. In one or two counties, the soil and climate of which seem unusually well adapted to their growth, large quantities are grown in the open air for the London markets; from such sources there are said to be sent to London not less than 600 tons a week during what is termed the Cucumber season. Of these upwards of 100 tons have been known to be sent to Covent Garden in a single day. What an acre of Cucumbers realises in the way of money is uncertain; but they are stated to yield a good profit to the grower even if he should get no more than 1d. or 2d. a dozen for them. At these prices sums varying from £20 to £60 per acre, according to the season, are said to have been obtained for them. In good Cucumber-growing localities, the seed is sown about the beginning of May, where the plants are intended to grow, in rows some 4 ft. apart, and the plants stand nearly 2 ft. asunder in the row. In favourable seasons they soon push into active growth and cover the ground with vines, which, during the latter end of May, the whole of June, and beginning of July, spread in all directions and come into bearing. During their growth, weeding and thinning their superfluous shoots are well attended to, and if the plants should not entirely cover the ground, or wherever blanks occur, Mangold Wurtzel is planted in the vacant spaces. About 4 yds. apart are also rows of Onions, set early in the spring, which, being allowed to run to seed, serve in some measure both for shade and shelter. Where Onions are not used for this purpose, Rye, sown in the autumn, 4 yds. or 5 yds. apart, and cut as soon as the vines cover the ground, is employed instead; Peas are also sometimes used for the same purpose. In this way the ground is made to produce two or three kinds of crops at the same time, and if one should happen to fail, one or more of the others, as the case may be, take its place. By the middle of July or earlier, according to the season, the crop is ready for a first gathering, and from that time to the end of September fruit varying in length from 10 in. to 12 in., green and solid, though sometimes unshapely, is continually being cut, sometimes to the extent of three tons at a time, and that from little more than as many acres. When gathered the fruits are sorted, the best being sent to London, second-rate kinds to the provincial markets, and what are small, crooked, or discoloured are given to pigs. Ripe ones are saved for seed, so that little or no waste is ever experienced with crops of this kind. The baskets in which Cucumbers are sent to market are called "pads." In shape they are square, with hinged lids, and they hold about two bushels.

GHERKINS.—These are extensively cultivated in London market gardens, some growers frequently gathering from 18,000 to 20,000 fruit in one day. The seed is sown in May in rows where the plants are to remain in well manured land. The rows are usually about 9 ft. apart, and the plants, which are thinned out when sufficiently advanced to admit of the strongest being discerned and left, are allowed to stand 6 ft. apart in the rows. The after treatment is exactly the same as that practised in the case of outdoor Cucumbers, except that the shoots of the Gherkins are allowed to grow unpinched. The fruit is gathered when about the size of a man's finger, placed in bushel baskets, and sent direct to the pickle manu-

facturers. A good place for Gherkins, and one often devoted to them, is the alleys between the rows of spring-sown Cabbages or Radish beds. The alleys are dug over, the drills for the seeds opened in the morning, and the seeds are sown in the afternoon when the ground is warm. When the Radishes or other crops are cleared off the intervening beds, the latter are dug, and a line of Cauliflowers or French Beans is planted along the centre of them, or sometimes two or three lines of Lettuces are put in. Some sow the Gherkins on an open quarter in patches of three or four seeds together, in rows about 5 ft. or 6 ft. apart, and 3 ft. or 4 ft. asunder in the row. Hand-glasses are then placed over the seeds, and when the young plants have come above ground abundant ventilation is given until they show flower, when they are fully exposed. Others sow a few seeds in the middle of the space between fruit bushes for about 6 ft. or 10 ft. into the brake, but no further. Thus, being near the outside, they get plenty of air and light, and have, in addition, the shelter of the bushes. In most cases, however, they are raised in frames and transferred to the open ground in June, and in this way they fruit earlier and usually give less trouble and better results.

C. W. S.

TREES, SHRUBS, AND WOODLANDS.

JAPANESE MAPLES OF THE PALMATUM TYPE.

THESE, in common with many more excellent shrubs, have for a long time been under the ban of a false frost-tender reputation, which has unfortunately hindered their propagation and prevented them from taking that place in British landscapes which they long ago might and ought to have occupied. I have once before, somewhere about this time last year, had something to say concerning the beauty and hardness of one of these Maples, and it is with the proofs before me which the incontrovertible severity of the past winter has given of the frost-hardy character of these shrubs that I am again induced to make an effort to redeem them from almost utter neglect, and, if possible, instil into others something of the admiration which I myself have for them. Here, in Derbyshire, fully exposed during the past winter, the smallest twigs of these plants were uninjured by a zero cold, and later, when in spring they shot out their frail growth 1 in. or more in length 10° of untimely and unlooked-for frost one morning failed to hinder them from developing their thin shoots and handsome, palmate, dissected leaves of all shades, from Apple-green to the most brilliant crimson; and now they are in all their glory, pleasant to look upon, and giving, as it were, by means of contrast, a new interest and aspect to their naturally more sombre associates.

The common *Acer palmatum* forms a dense average-sized shrub, having numerous long thin shoots and opposite small palmate, at first light, afterwards dark green leaves. A *p. atro-purpureum* has larger, at first bright, afterwards dark, red leaves on stouter shoots. A *p. dissectum* has finely-cut skeleton-like elegant apple-green leaves, equalling the finest Ferns in their Vandyke veination. Sub-variety *rubrum* of the last is characterised by its reddish-brown leaves, and presents a fine contrast to the last named. Both are very attractive either in the mixed shrubbery or singly on a lawn. They ought to be planted close to walks in order that the tracery of their elegant leaves might be the better studied.

I have enumerated the most distinct and striking of the varieties for outdoor planting, but there are many more polymorphic forms some of which have prettily variegated leaves, but though all are perfectly hardy, they are better calculated for conservatory decoration than for any decided effect out-of-doors. I am not going to underrate the qualities of such ornamental plants as purple Oaks, Beeches, &c., but I only say that A *p. atro-purpureum* is the most ornamental shrub of all. Seen near, its foliage is not only dazzling, but also exceedingly neat; seen from afar, it scintillates among other shrubs like a ruby. May I be allowed to suggest, if it has not already been carried into practice, that this plant might be advantageously used for bedding purposes? Plants, say, from 1 ft. to 2 ft. in height planted permanently in beds would produce such a show as no *Alternanthera*, *Iresine*, or similar plants are capable of making, and though the plant in question is deciduous, the bare twigs in winter need be no objection to its use in this way, as even nude twigs are surely as pleasant to look upon as the bare black soil of beds in winter, all the more conspicuous after the fiery glare of autumn has vanished.

Borrowash, Derbyshire.

G. SYME.

FORMS OF LEAVES.

ONE of the most frequently used characters in the description of plants is the form of the leaf. This can hardly be wondered at, seeing that it is one of the most striking and, generally speaking, one of the most constant characters possessed by the plant. It is, however, far from being invariable, and cultivators are frequently witnesses of changes of this kind which never come within the ken of the scientific botanist. The Olive, for instance, bears nearly circular leaves on the ground shoots, whereas the ordinary leaves are six or eight diameters in length. Several species of Ivy bear heart-shaped leaves at the end of their long watery shoots, the normal leaves having five and seven lobes. The common Bramble also varies greatly in its leaves even on the same shoot, but the example we are about to cite is still more extraordinary than any of those already mentioned.

For many years past we have noticed that in making sowings of *Sorbus aria pinnatifida* (figs. 1, 2, 3) a number of the seedlings always appeared to belong to different species, if we may judge by the forms of the leaves, some of them bearing simple and others compound leaves, the former closely resembling those of the Bird *Sorbus*, a fact which led us to doubt the authenticity of the seeds. But seeing that these discordant results were produced so constantly, we determined to procure the seed from a source which was beyond all possible doubt. We even went so far as to collect the seeds ourselves from plants in our own possession, which we sowed in pans in virgin soil, placing them under a frame in a greenhouse to which we ourselves alone had access, but always with the same results as when we made sowings from seeds procured through the ordinary channels

Fig. 1.—Shoot of *Sorbus aria pinnatifida* with simple leaves.

and sown in the open ground. The forms shown in figs. 1 and 2 were not the only ones that we found amongst these sowings. They are, so to speak, the extremes of the series, between which we found every possible variation. One example of this is shown in fig. 3, in which the leaves are only slightly indented at the lower part. What is the lesson to be learned from these facts, of which we can personally guarantee the exactitude? A number of conclusions may be drawn from them, the principal one being that *Sorbus aria pinnatifida* is not a species properly so called, but only a variety. We are not only quite willing to admit this last-named fact, but we will go further, and even allow that this plant is a hybrid—that convenient term with which so many botanists in a state of distress and bewilderment seek to account for facts which they cannot otherwise explain. But this easy method of getting out of a difficulty is really but of little worth, seeing that these terms—variety and hybrid—are of the vaguest possible character, and cannot be used in any definite sense where scientific principles are in question. Such arguments generally recoil on the heads of those who use them, and render the so-called demonstrations utterly false and worthless. If we allow that *Sorbus aria pinnatifida* is a hybrid or a variety, how many other so-called species may we not place in the same category, most of which reproduce themselves continually with almost unswerving uniformity? In fact, we should have to include under this head the major portion of those varieties which botanists consider to be separate species. On the other hand, if we examine the opinions of botanists on the subject of the plant of which we are speaking, we shall find ourselves in another difficulty, which cannot be solved easily even by scientific botanists, the facts of the case being opposed to each other in such a way as to greatly weaken it. The plant we are speaking of bears at least six synonyms, if not more, being included under no less than five different genera by as many botanists. We

Fig. 2.—Shoot of *Sorbus aria pinnatifida* with compound leaves.

genus *Sorbus* and lies in the vicinity of *S. aria latifolia* and *intermedia*; in fact, it only differs from these species by the lobes of the leaves at the base being indented more deeply, while, as for the other characters—habit, growth, general appearance, flowers, and fruit, they are exactly similar. Our principal object, however, in writing this article is not to interfere with the nomenclature of this plant, but to show, by an indisputable example, that, contrary to the usually admitted opinion, there is no absolute limit to be drawn between simple and compound leaves, and that we may pass from one to the other without any very striking gaps, a fact which is in strict conformity with the grand law of natural harmony, which embraces and unites all, by showing that wherever there is unity of principle the deviations from it are always relative, an opinion which we always have and always will maintain. We may formulate our views in

Fig. 3.—Shoot of *Sorbus aria pinnatifida* with partially cut leaves.

the following axioms: Wherever there is unity of composition differences can only arise from diversity in the arrangement of the parts, the forms of plants being, so to speak, nothing more than the clothes which conceal their life. From these two axioms we may deduce a third, viz., all plants, being composed of the same elements, are allies or relations. It is not a question of greater or smaller. The creation is infinite and infinitely variable in all its parts.—*Revue Horticole*.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Outdoor Camellias.—I commend the following passage in reference to these to the notice of "Cambrian" (see p. 414). He will find it in the second page of the first volume of the second series of Sweet's "British Flower Garden." "The Camellia is not generally so much cultivated as it deserves, though it is very hardy, standing our severest winters when planted out against a wall, or in any sheltered situation without protection; but being such an early flowering plant, the buds are often much injured and sometimes destroyed, if not covered a little in severe frosty weather. We believe a northern aspect would suit it better than a southern, as it would not be so liable to sudden and frequent thaws in the day and frost at night, which injures plants that are somewhat tender more than they are injured by not being thawed while the frost lasts. We have proved this," &c. My experience is altogether on the side of Mr. Sweet, and against that of "Cambrian." I believe that Camellias do best in a dull retired nook, where the direct rays of the sun can never reach them, and where their roots can be always kept moist. That they thrive well and blossom under conditions such as these anyone could see by looking out of my window.—HENRY EWANS, *Ryde*.

Chinese Method of Raising Weeping Trees.—It is stated in Regel's "Gartenzeitung," on the authority of Dr. Bretschneider, physician to the Russian Embassy at Peking, that the Chinese raise weeping trees by reversing their extremities. Dr. Bretschneider describes the operation, which he asserts he has himself repeatedly witnessed, as follows: "To raise weeping trees of *Sophora japonica*, they plant two young seedlings side by side. The tip of one of them is then bent downward and marched on the base of the other, tip downward. As soon as the graft has properly taken, the tree that was doubled down is dug up, roots and all, and the roots, denuded of the soil, turned uppermost, and the stem attached to a stake in this reversed position. The stem of the tree, which serves as stock, is then cut off at the point of union of the two, and the roots of the reversed tree form the crown of the artificial tree. In this novel position they require shading from the sun until they have formed some branches." In this manner, we are assured by Dr. Bretschneider, as translated in the *Gardeners' Chronicle*, the Chinese obtain all their weeping trees.

Weeping Cedar of Lebanon.—For the past twenty years I have admired an exquisite specimen of the true Weeping Cedar of Lebanon which stands in the grounds of the house called Menival, the second house on entering the village of Dulwich from the London end. The tree is quite visible from the road, and its gracefully pendent branches flow over one another and roll out in waves upon the Grass in a manner that reminds one of the falls of Niagara, and leads one to think while looking at it that it is the most beautiful of all Conifers. The tree looks about 30 ft. high, and is probably eighty years old, and bears cones freely. The only other specimen I have seen is visible over a wall by the riverside in the village of Sunbury, and appears of similar age. I have for years sought for this Weeping Cedar in vain in the nurserymen's catalogues, and presume it must be out of cultivation.—LATIMER CLARK.

Paul's Double Scarlet Thorn.—Thorns, or, as they are commonly called, May trees, when planted in irregular groups in parks have a pretty appearance, the whiteness of the common kind being greatly enhanced when contrasted with pink and red kinds, both double and single, and amongst these Paul's Double Scarlet is a real acquisition. We have some vigorous young bushes of it, and the lovely clusters of bloom which they produce look more like bunches of scarlet Banksian Roses than anything else with which I can compare them. In every garden, however small, space should be found for so beautiful a tree, as, whether on the Grass or peeping out of the shrubbery, it is always effective.—J. GROOM, *Linton Park, Maidstone*.

Deutzia gracilis.—One of the prettiest sights at present in the pleasure grounds here is a large irregular bed edged with this *Deutzia*, the long shoots of which are wreathed with delicate snow-white blossoms in such abundance as to look like masses of the purest driven snow. Beautiful as this well-known shrub is as a decorative plant under glass, it is even more beautiful when growing luxuriantly out-of-doors.—J. GROOM, *Linton, near Maidstone*.

The White Indian Azalea Out-of-doors.—Our white Azaleas have not only withstood the past winter out-of-doors entirely unprotected, but are now flowering freely, the blossoms being exceptionally fine and pure white in colour. I see no reason why Indian Azaleas in sheltered situations should not eventually become popular as outdoor shrubs.—J. GROOM, *Linton Park, Maidstone*.

Actinidia kolomikta.—A peculiarity in this hardy shrub has lately come under my notice which I think worth recording. The plant is against a wall, and as soon as the first spring leaves appeared

it was pulled down and almost destroyed. I attributed this to the cats using it as a ladder to get over the wall. It was fastened up again and protected with a wire grating, and soon sent out vigorous shoots. On Monday evening last the shoots were nailed and the wire fencing removed, and before Tuesday morning the whole shrub was violently pulled from the wall and much broken, and almost every leaf stripped off. I have no doubt cats are the culprits, but for what object do they do this mischief? They do not eat the leaves, nor do they seem to roll in them as they will in Valerian, and I can detect no smell in them. It adds to the mystery that in another part of the garden I have another species, *A. polygama*, not against the wall, which they have not touched.—HENRY N. ELLACOMBE, *Bilton Vicarage*.

PLATE CLXXXVI.

THE HARDY RED WATER LILY:

(NYPHÆA ALBA VAR. ROSEA.)

Drawn by ALFRED PARSONS.

THIS Lily is undoubtedly the most interesting and beautiful addition we have lately had to our aquatic flora; but is there any reason why it should not be further enriched by the multifarious colours of the sub-tropical species? Would it not be possible, for example, to raise hybrids between the hardy *N. alba* and the more brilliant *N. stellata*, &c., using the former as the seed-bearing plant? If the experiment has not been tried, it is worth trying. Putting aside speculations as to what may possibly be obtained in the way of hardy Water Lilies, we may congratulate ourselves on the present acquisition, for there seems to be no doubt respecting the permanency of the colour of the variety *rosea*. It was at first suggested that the colour might be due to local causes, and would possibly be lost under cultivation. Whatever the origin of the colour, some eight or nine years' cultivation prove that it is fixed. This beautiful Lily is a native of Sweden, where it is only known to exist in one remote lake—Lake Fagertårn, in the parish of Hammar. It was discovered in 1856 by a Mr. Kjellmark, and, as far as we have been able to ascertain, it was first published as a variety *rosea* in Hartman's "Scandinavian Flora," edition 10, 1870, p. 86; since then the same variety, from the same locality, has received two other names; a fact to be borne in mind in order to avoid disappointment. It should be added that these names were inadvertently given by different botanists who were in ignorance of each other's work, and not with the intention of misleading the public as to the identity of the plant. Professor Casparz, the director of the Botanic Garden at Königsberg, who has made the Water Lilies his special study for a great many years, procured living plants and propagated them, and in 1871 offered them for sale at 6s. each. At the time he made the announcement, he published the variety in the "Botanische Zeitung," 1871, p. 874, as new, under the name of *Nymphæa alba var. rubra*, explaining that it differed only from typical *alba* in the coloration of its flowers. Professor Casparz also gives directions respecting the successful cultivation of this and other Water Lilies, which may be repeated here. He observes that to grow it fine, other things being equal, it must not be too much confined to space. There is of such general application that it would seem almost superfluous to mention it had we not every day evidence of overcrowding. As a minimum it should have a superficial area of 12 square feet in water from 1 ft. to 2 ft. deep; 18 in. is a good average depth where it can be controlled. The third name was given to our Lily in Fries' excellent "Herbarium Normale," where it is called *Nymphæa alba var. purpurea*. The dried specimens of this collection are very fine, and the flowers, which are 6 in. in diameter, retain their original deep colour. Fries himself must have been greatly impressed with their beauty, for the label accompanying the specimens in question bears the significant legend: "Maximus et speciosissimus in Europa flos, Victoriani æmulans," or, in plain English, the largest and most beautiful flower in Europe, emulating the Victoria. The first coloured plate of the hardy red Water Lily was published in the supplement to the "Flora Danica," t. 141, which, however, represents the flowers of a much paler colour than those we have seen cultivated in this country. It has been successfully grown at Kew, where it produced good flowers last year; but, as already stated, it has been cultivated for some years on the Continent. The first notice that we saw of it in English periodical literature was in Trimen's "Journal of Botany," 1872, p. 329. Dr. H. Trimen there records having seen it growing in the Botanic Garden at Lund, where he was informed of its origin by Dr. Areschoug. Every cultivator of hardy aquatic plants will be anxious to possess this beautiful novelty, and, as the propagation of this class of plants is not difficult, we may look forward to their wishes being speedily gratified.

W. B. HEMSLEY.

THE BEST VARIETY OF THE COMMON WATER LILY

GARDENING FOR THE WEEK.

Flower Garden.

Auriculas.—Seed pods of these are not filling well this season, except in cases in which the flowers have been carefully fertilised. It may be as well to state, in reference to hybridising that much judgment is necessary in the selection of parents, and that seeds saved from self-fertilised flowers are not likely to produce many distinct and good varieties. Young seedlings have grown vigorously during the last few weeks, and they must be provided with more room as roots and leaves increase. It is interesting to witness the development of the leaves; at first they are quite green, but the older ones gradually become coated with farina as they enlarge. We still find small plants appearing in the seed pots, and these are picked off as soon as they become large enough to handle.

Carnations and Picotees.—It is necessary to devote careful attention to these just now, as any check to their growth would be fatal to the development of full-sized, well-marked flowers. Keep the surface of the soil free from *Conferve*, and remove all decaying leaves. Tree Carnations are now making good growth, and must be shifted into larger pots as they require it. I have seen these plants potted into very large pots, but that is a mistake. Our largest plants are permitted to flower in 8-in. pots, and smaller plants do well in 6-in. and 7-in. ones. What they require to grow in is good turfy loam, well enriched with rotten stable manure and crushed bones, and they must be well supplied with water at the roots all through the growing season. At present they succeed best out-of-doors; the pots should be placed on a hard bottom, in order to prevent worms from getting through. I never at any time use manure water; the only time when this is useful is when the plants have become exhausted from flowering freely.

Dahlias.—The advice given some time ago was to leave the plants in their pots until the weather had become fairly settled. This has now happened, and nearly all the plants will have been put into their blooming quarters. Ours are growing freely, and as the side shoots develop, all of them are pinched out but three or four. These side stems must have smaller sticks than the centre one placed to them as soon as they are strong enough to need support. Flowers will form on the centre stem of many of the plants, but these must be pinched off up to the time when the blooms will be required, as no one cares to see Dahlias in bloom shortly after midsummer. There is no need to water, as the ground seems to be sufficiently saturated to last through the season.

Pinks.—This is now the best time to put in pipings. The smallest growths strike root most freely, and if the weather is dull and showery at the time when they are taken off, they may be put in a shady position quite in the open ground. I have propagated them in that way in Scotland and not lost 5 per cent. of them. It is rather more difficult to propagate the Pink in the south than in the north, and in dry sunny weather it is best to place the pipings in boxes, and to strike them on a very mild hotbed. They must be shaded from the sun until roots are formed.

Pansies.—It is a good plan to put in some cuttings now to form a late autumn bed. The season has been very favourable to the growth of Pansies so far. If it is intended to have good flowers for an exhibition or other purpose on a given date, pinch off all the flowers that are open or nearly so—indeed, even buds that are showing colour—about a fortnight before the date on which they are required. No flower degenerates more rapidly than Pansies, and the only way to maintain them in good condition is to occasionally denude them of flowers and apply surface dressings to the beds.

Phloxes in Pots.—The utility of these for conservatory decoration has already been alluded to, and they must now be well attended to, in order to have them very strong at the time of flowering. The Phlox is a gross feeder and absorbs an enormous quantity of rich stimulants, either in the way of surface dressing or manure-water, not too strong. Tie the growths to stout sticks as they advance, and place the plants where they can obtain plenty of light and air.—J. DOUGLAS.

Ferns.

There is no season of the year when Fern houses have a more beautiful appearance than at present, when the different tints of the young green fronds are in most cases developed. Everything possible should be done that will tend to preserve them in good condition. Unless these plants be free from mealy bug, scale, and thrips, it is impossible to keep them in a satisfactory state all through the year; the two former, from their glutinous excretions, to which the slightest dust adheres, soon cause the fronds to look black and dirty; and the thrips, though easier to kill, not only disfigure the

fronds by destroying the outer cuticle, but also cause them to die off prematurely. Where an effort was made, as recommended, during winter, to kill outright or reduce, as far as possible, these pests, the improved condition of the plants will be apparent, and whatever insects have escaped should receive no quarter. The fronds will not be in a state now to bear a strong enough application of any insecticide to kill scale and bug, and these should be sought for and removed by sponging. Tobacco water is the safest remedy for the thrips. Any plants in small pots or tubs, particularly of the Tree species, will be much assisted by frequent applications of manure water moderately strong; this will be especially beneficial in the case of such kinds as are naturally of a pale yellowish tint, like the *Cibotium Schiede*, which ought to be in every collection where there is a house large enough to grow it; for, although it is very wide-spreading, it is of dwarf habit, with a stem insufficiently tall to admit of passing under it in the way the tall-trunked kinds allow of; but where there is a projection of rock or roofwork it can be elevated with the best effect; or a stout trunk of a tree may be used for a like purpose. Where a large collection is planted out, it is necessary at this time of the year to see that the strong growers do not encroach upon the weaker ones; this can be effected by cutting the older fronds away freely, which will at once reduce the size of those that are to come. The advantage of this during the season of growth, when replanting cannot be carried out, will be obvious.

Orchids.

Cool Orchids.—The cultivation of these, so as to attain the highest strength and vigour of which they admit, is much easier when the house in which they are located is of a character best suited to their requirements. The *Odontoglossums*, which collectively constitute the most important genus that comes under the denomination of cool Orchids, with a few exceptions, are plants that in their requirements fully realise the term cool, for not only will they bear a low temperature when at rest, but they are much averse to a high one when growing; the form and position of structure which best suits them is no doubt a lean-to facing the north, not too high or overshadowed by a wall higher than where the top of the roof-glass abuts against it, as when the house is attached to a wall or high building that extends considerably above it, light, one of the most essential elements to a continued healthy vigorous condition, does not reach the plants in sufficient quantity; this is evident from the strong spikes and profusion of flowers which are generally produced by plants with smaller pseudo-bulbs and less leaf development, the result of growth under enough light as compared with the size they attain where there is a deficiency of this. Where a house of the description alluded to is not available, and these plants have to be grown in a lean-to structure facing the south, or in span-roofed houses in any position under the full influence of the sun, it is a difficult matter to keep the heat from rising too high during this and the next two months, as a temperature even in the daytime of 65° to 70° will suit them better than higher. In such houses the advantage of thicker shading advised some time since will be obvious, as by the use of this the over-abundant sun-heat can better be kept out, to still further assist which the rollers and blinds should work on strips of wood just sufficiently strong to carry them, fixed 10 in. or 1 ft. above the glass, which will keep the shading material enough elevated above the roof to allow a continuous current of air passing between. Air should be plentifully admitted night and day, the floors, walls, and stages on which the plants stand kept continually wet, and the material in which they are grown equally well supplied with water. The amount of flower, comparatively large for the size of the plants, which the species of *Odontoglossum*, such as *O. cirrhosum*, *O. Pescatorei*, and the different forms of *O. crispum*, especially bear, and the great length of time the flowers last upon the plant, if allowed to remain until they decay naturally, is a severe tax upon the growths from which they are produced, as is evident by the way in which the pseudo-bulbs generally shrivel, and are some weeks afterwards before they regain their plumpness. This, with the exception of those that have flowered very late, they will by this time have done. Where re-potting is necessary, or any division of the plants is contemplated, anxiety to carry out the work, so as to allow as long a period as possible for the growth to complete, frequently induces the operator to pot or divide the plants before the pseudo-bulbs have regained their plumpness after flowering; but this I have found to be a dangerous practice, as the unavoidable breakage and disturbance of the roots in re-potting have the direct effect of cutting off the source from whence the bulbs become reinstated in their plump healthy condition, without which the young growth immediately proceeding from them cannot be expected to ever be equal to that arising from plants that have fully regained their wonted condition after the exhausting effects of flowering; and from this cause I have often seen healthy plants of *Odontoglossum*, instead of going on yearly increasing in strength and vigour, and so being able to produce double breaks, much deteriorate. There is a

considerable difference in the material employed by growers of these plants, but after trying a mixture of Sphagnum and peat in quantities more or less disproportionate of each from nearly all peat to nearly all Sphagnum, I have found that about half and half of each resulted in the strongest growth. Requiring as does this section of Orchids to have the soil in which the roots exist continuously wet almost up to the point of saturation, it is evidently necessary to guard particularly against the possibility of its becoming sour, to avoid which the peat and Sphagnum should have something like one-third of their bulk added of broken crocks. These directions, so far as the potting material is concerned, with very few exceptions, hold good in respect to all Orchids that need the soil to be kept very wet.

Intermediate House Cattleyas.—The numerous section of spring-blooming Cattleyas, including the many and beautiful forms of *C. Mossie*, *C. lobata*, *C. Skinneri*, *C. Aclandiae*, *C. intermedia*, and *C. Warneri*, will have completed their flowering, and had sufficient time for the bulbs that have produced the blooms acquiring their wanted plump condition, for, in their case as much or even more than the cooler section it is necessary for them to have fully recovered from the shrivelling effects which the production of their large fleshy flowers invariably has. The injurious result of this untimely disturbance of the roots that takes place when these plants are made up when in flower by putting several together, a practice so common with exhibitors, is almost always evinced by the weakened condition that follows for a year or two afterwards. Whatever re-potting, with or without division of the plants, is necessary, should be effected as soon as they have regained their normal state in the way above described; with these I should advise as much as possible of the earthy matter being got out of the peat before mixing it with the Sphagnum, in all cases adding a sufficient supply of crocks proportionate to the increased size of pots employed. The extent to which the roots of vigorous healthy Cattleyas adhere to the insides of the pots, or whatever they come in contact with, and the impossibility with even the greatest care of removing them without breakage afford ample evidence to the least observant that re-potting should be resorted to as seldom as possible, yet when the stems have so far advanced that the young growths formed extend beyond the rim of the pot, it becomes at once necessary to give more room, for the roots produced from such are not in a position to receive any nutriment except from water, which they get either by direct application, or through the humidity of the atmosphere, the insufficiency of which is shown by the diminished size of the bulbs made under such conditions. With a view to avoid shifting these plants oftener than may be needful, it becomes necessary to give them pots sufficiently large, yet they must not be too large, and must be regulated in a great measure by the quantity of water given not only when at rest, but through the growing season; but where Cattleyas are grown under the system of comparatively little root moisture as compared with that which is necessary for most other Orchids, I have proved by experience that there need be no fear of the destruction of roots often supposed likely to result from the use of pots larger than necessary to accommodate them for a couple of years or so. After potting keep the atmosphere surrounding the plants a little closer and more humid than usual for a few weeks so as to avoid the necessity for much water being applied to the soil, otherwise the broken roots instead of healing up and commencing growth are liable to rot back for a considerable portion of their length. Slight dewings with the syringe overhead will still further assist them in this way.

Summer and Autumn-blooming Cattleyas.—Of these the old but beautiful *C. crispata*, so charming and distinct, requires special treatment at almost all seasons; if the development of the flowers is not very slow and brought forward in a comparatively dry atmosphere, the blooming will not last half as long as it will where these precautions are taken. The conditions required are found to be such as are present in an ordinary Vinery where the Grapes are wanted at an intermediate season; here there is sufficient warmth and moisture in the atmosphere, with air and shade, that will give the flowers substance to last well for three weeks or more. The later-blooming kinds, such as the true *C. labiata*, *C. violacea*, the different forms of *C. speciosissima*, the beautiful hybrid *C. exoniensis*, and the *C. Trianae*, will now be in different stages of their growth. The two-leaved kinds usually flowering about the end of August or September will need less water to the roots than those whose growth is not so far developed; and all should be supplied now with the maximum of heat they require through the season from 55° to 65° in the night, with from 75° to 80° in the day, according as the state of the weather will suit them.

Lælias.—*L. purpurata* and *L. elegans* and others requiring an intermediate temperature and flowering through the spring and early summer will need, as regards potting, water, air, and general management, to be treated as advised for the spring-blooming Cattleyas, using no more shade than necessary to preserve the colour of the

leaves, with a free admission of air for some hours in the middle of the day, dewing the plants overhead with the syringe at the time of closing the house, treatment which I have found of the greatest benefit to a healthy development of growth; neither have I ever found that *Lælias*, *Cattleyas*, or all this section of Orchids suffer in any way from the use of the syringe when they receive enough air and light, and are not subject to the enfeebling influences of too much heat and atmospheric moisture, in which latter case syringing often results in the loss of the young growths.

Indoor Fruit Department.

Vines.—Now that Grape-thinning has been brought to a close, the main requirement will be to keep the lateral growths well stopped back, in order to prevent overcrowding. Should there be no danger of this through the Vines being at long distances apart, then allow the laterals to grow till such danger appears. Inside borders of Vines swelling their fruit will take any amount of manure water, and, as soon as applied, the borders should be mulched with 2 in. or 3 in. of fresh stable litter in order to retain the moisture and supply the atmosphere with ammonia. More than this quantity would prove too powerful and injure the foliage. Ventilate freely in the early part of the day and shut up early in the afternoon, making free use of water to engender atmospheric humidity; give a little air at 7 p.m., and leave it on all night. Grapes that are ripe or ripening cannot have too much air, unless the wind prove exceptionally harsh, which is rarely the case at this time of the year. Usually all atmospheric moisture is recommended to be withdrawn when colouring begins, but we have come to regard a moderate amount as beneficial, inasmuch as it prevents an undue development of red spider should that pest have gained a footing. Pot Vines intended for early forcing next year should now have completed their growth, which will now, as it were, require to be consolidated and ripened by the fullest exposure possible to light and sunshine. Keep lateral growths closely pinched, but the main shoot may still be allowed to grow on unrestrictedly. The plants should still have abundant supplies of root moisture.

Peaches and Nectarines.—Fruits of these in the first early houses will now have come to an end, and the trees may now be overhauled, thinning out all unnecessary shoots, especially those that keep light and air from acting on the wood that is intended for fruiting next season. If this be done now, little if any winter pruning will be necessary. Resume syringing and keep the borders well supplied with moisture. Treat succession houses as recommended in former notes for early houses, except that there should be an increase of air-moisture now that the days are longer and warmer. Ripening fruit should be fully exposed to light if it is to colour and gain off well.

Strawberries.—The forcing of these is barely over, and yet preparation must forthwith be made for that of another season. Owing to the rain, runners are plentiful much earlier than at one time was expected, and as early layering and consequently early maturation of crowns are the mainstays of successful Strawberry forcing, at any cost this operation should have immediate attention. We always layer our first Strawberries (about a couple of hundred) in 5-in. pots, in which they are allowed to fruit, and which they do much better than those layered at the same time in larger pots, the reason being that the pots get sooner crowded with roots, and this induces earlier ripening of the crowns which, as a matter of course, must fruit earlier than they otherwise would do, and as they are forced at a dull and sunless period of the year, no inconvenience arises from their requiring to be watered oftener than those in larger pots. We layer the general stock in 3-in. pots, and as soon as the roots reach the sides of the pot we shift into 6-in. pots. The best soil is moderately stiff loam without any admixture except a small proportion of bone dust or horn shavings. Careful crocking to admit of free drainage is imperative, as is also firm potting. After potting place the plants in an open position, well supply them with water, and keep all runners picked off as soon as they are produced.

Figs.—In many instances the first crop of fruit will now be gathered, and the trees may again be regularly syringed and be liberally and frequently watered with guano or other manure water. An excess of humidity is now all but impossible provided sufficient air is given to daily renew the atmosphere, as anything like a stagnant condition must ever be guarded against. Rub off surplus fruit, and avoid laying or tying in too many new shoots, which both prevent the ripening of the wood and the flavouring of the fruit. Where the latter is ripening, keep both atmosphere and roots somewhat dry—but neither arid nor dry, and do not gather any fruit till there are symptoms of its bursting at the apex, for till that takes place it is not in perfection. The fruit will keep in a cool, airy room several days after being gathered in good condition.

Kitchen Garden.

The almost daily rainfalls which we have had have rendered hoeing impossible; therefore the most urgent requirement in this department now is hand-weeding, for even if the weather should be favourable for hoeing the majority of the weeds are too large for the work to be done effectually in that way; at the same time, should the weather prove favourable, hoes will require to be freely used after weeding in order to induce a quicker growth through the aeration of the soil. The moist state of the ground has been favourable to the thinning out of all seedlings, and also to the planting out of the earlier varieties of winter Greens, Broccoli, Cauliflowers, Coleworts, and Celery. Any of these not yet planted should have attention before the season is too far advanced.—W. W.

THE INDOOR GARDEN.

UTILISING DEAD TREE FERN TRUNKS.

The sketch from which the annexed woodcut was prepared was taken in one of the Ferneries at Messrs. Veitch & Son's nursery,

Lomaria attenuata on a dead Tree Fern trunk.

Chelsea. It represents *Lomaria attenuata* growing on a dead Tree Fern trunk, which is clothed also with innumerable sporophylls of various other Ferns, such as *Nephrodium molle*, *Polypodium Billiardieri*, *Lomaria blechnoides*, &c. This is a desirable method of growing Ferns, as they look more gracefully and naturally than when cultivated in pots, and they do not require so much attention, as the roots insinuate themselves into the soft but solid texture of the Fern stems where they are kept at an equable state as regards moisture if water be occasionally applied. Under this treatment some kinds of Ferns thrive better than when grown otherwise, whilst others do not succeed so well. The kinds that thrive best are the *Lomarias*, *Nephrolepis*, *Davallias*, *Doodias*, most of the *Polypodiums*, many *Spleenworts* and *Maiden-hairs*, &c. A highly attractive

feature, too, is the wing of the large tropical Fernery at Kew, where there are admirable examples of this style of growing Ferns, thriving in native luxuriance, mingled with the various kinds of *Tradescantia*, *Saxifraga sarmentosa*, and *Chlorophytum orchidastrum*, &c., and all the attendance they receive is occasional watering and a daily syringing. W. G.

ORCHID GROWING IN AMERICA.

PERHAPS the following note may interest some of your readers, as it tends to show what rapid strides have been made on this side of the Atlantic with regard to the cultivation of Orchidaceous plants, some of the collections of which, both in point of numbers and size of specimens, are not far behind the best of those in England, though, of course, the taste for them has not attained such popularity as in England, yet there is evidently an increasing demand for them in many of the States. The collection to which the following remarks allude is in the gardens of Erastus Corning, Esq., Kenwood, near Albany, New York, in which at the present time (June 4) there are upwards of 120 distinct species and varieties in flower, and the majority are represented not by small-sized plants, but by really good specimens, such as would favourably compare with those in the best English collections. Amongst those in flower of special note are the rare *Renanthera matutina*, with its singular blossoms and equally strange colouring, the beautiful *Lælia Wolstenholmie*, *Aerides Schroederi*, *A. Larpenæ*, the curious *Bulbophyllum Henshallii*, *Promenaea stapelioides*, and *Nanodes Meduse*. Of *Odontoglossums* there are, amongst others, fine plants of *O. vexillarium* and *O. Alexandre*, some of the latter bearing as many as twenty or thirty flowers on each stem. The various kinds of *Phalenopsis* are now on the wane as regards flowering; the recent addition of an unique specimen of the beautiful *P. Corningiana*, dedicated to the owner of this noble collection by Prof. Reichenbach, has considerably added to the interest of the collection. *Cypripediums* are numerous represented, including the fine hybrids *C. Crossianum* and *Swainianum*, as are also the *Epidendrums*, of which *E. Friderici Guillelmi* and *E. syringothyrsus* are the most noteworthy. The collection is rich in *Masdevallias*, and the curious *M. nycterina*, *M. elephantipes*, *M. Bella*, together with the showy kinds, have been long in flower. The white-flowered variety of *Lælia Skinneri* is a superb kind, and should be in all collections. Another beautiful variety is a rich-coloured form of *Vanda tricolor* named Corningi, and quite worthy of its distinctive name. These are but a few of the many rarities in this interesting garden. FREDERICK GOLDRING.

***Bougainvillea spectabilis*.**—This is what we call a shy flowerer; but now and then, when it finds itself favourably circumstanced, it produces flowers in profusion. We have a plant of it here, now in full bloom, which covers a division of a half-span-roofed house between a greenhouse and Vinery; and it also occupies the adjoining roof sashes, the shoots being tied and trained close under the glass in order to expose them to full sunshine. Those in the apex of the house, where the heat accumulates, were the first to show bloom, showing us that the *Bougainvillea* delights in solar heat. Last year we turned it out of the pot it was in and planted it in a prepared place, bottomed with stones and also surrounded by them, close to a flow pipe. This stone tub, as it may be called, is about 2 ft. square by 1½ ft. deep and well drained, the soil being turfy loam, peat, and sand. It made vigorous growth last summer, and in autumn water was given so sparingly that all the leaves drooped during the day, but were revived by the morning; it was dry at the root, and seemed struggling for life. Nevertheless, this kind of treatment has resulted in a profusion of bloom. It was kept dry through the winter and spring months. It is, indeed, astonishing what an amount of drought the plant will endure without perishing. Along with this I send a shoot to show how well it has flowered. The topmost shoots under the sashes have been loosened in order to allow them to display their long pendent branches, laden with their floral treasures, to better advantage. *B. spectabilis* would undoubtedly be the glory of our hothouses could a display of its beauty be insured periodically.—J. JONES, *Penylan, near Cardigan*. [The spray sent was loaded with inflorescence of the very brightest colour. This is undoubtedly the best of all the *Bougainvilleas*.]

***Viburnum plicatum* under Glass.**—This handsome flowering shrub is very effective as a pot plant for conservatory decoration, the blooms being produced in pairs all along the wood of last year's growth. When they first open their colour is pale pink, but they soon become white. In the shrubby border this variety is much appreciated, the smaller plants of it flowering much more freely than the older and better known *Guelder Rose*.—J. GROOR, *Linton, near Maidstone*.

THE KITCHEN GARDEN.

SEAKALE FROM SEED AND ROOTS FOR FORCING.

IN "C. W. S.'s" remarks on Seakale culture in market gardens it is stated that market growers object to the practice of raising stock from seed on the plea that seedlings "occupy the ground for one entire year without any return, and also that during the second year they are sometimes liable to produce a profusion of small crowns; and unless these are reduced the plants form but weakly subjects for forcing." As doubtless many beginners will copy the practices described by your correspondent, and for the most part usefully too, allow me to say that the experience of market growers and gardeners in private places is considerably at variance on the subject of Seakale culture if the above quotation correctly describes the market growers' opinions and practices in the matter. In one of the earliest numbers of THE GARDEN, in an article on Seakale, I showed that plants raised from seed would be fit to force at the end of the same year, and the plan is one which has very much to recommend it under certain circumstances. I never knew before that seedlings that were thinned were apt to run to seed the first year, or that the plants were liable to produce a profusion of small crowns the second season. For the last fourteen years we have grown nothing else but seedlings here, and I do not remember ever seeing a single "bolted" plant during that time. They certainly "bolt" the second season, but if the seed-stalks be cut off as soon as they appear they will produce three or four strong crowns that will not seed, but produce good heads for forcing. Wherever space is an object, and where the climate and soil are of an ordinary favourable character, no one need trouble to grow Seakale for two years before forcing, either from seed or roots, who can content themselves with good average-sized crowns.

In good seasons we have had plants 5 ft. across from seed sown in April, and we have never forced anything but seedlings till the past winter, and the reason of this was that, owing to the cold and late spring in our exceptionally late district, our plants were hardly more than above the ground by the beginning of July, and many of them were smaller than usual, but many also were fit for forcing. This season being even more backward than the last, we have planted both seeds and roots for the first time. In most parts of England, however, and certainly in the south, or anywhere where the seed can be got into the ground towards the end of March or early in April with the prospect of the plants being above ground in May or early in June, a crop of fine roots fit for forcing the same year may be confidently expected, and instead of the plants occupying the ground for "an entire year" to no purpose, they need not occupy it longer than seven or eight months. Considering the way in which seedlings are treated generally, it is hardly to be wondered at that they are usually poor. Seed being usually employed simply to raise a fresh stock of plants, it is sown in rows 9 in. or 12 in. asunder, and the plants, not being thinned out, they never get large; but sown in rows 2 ft. asunder in good, well-prepared ground, and thinned out to 20 in. or 2 ft. apart, and observe the difference. I have seen seedlings treated in this way produce roots nearly as long and as thick as an Altringham Carrot, and tops when forced of proportionately good size. The only fault belonging to seed that I am aware of where the crop depends upon it is the danger of blanks occurring; but, by steeping the seed and sowing sufficiently thick enough, little risk need be incurred in this way. Rats and mice are almost as fond of Seakale seed as they are of Peas, but if the seeds are rubbed while moist in dry red lead before sowing they will be safe from such plagues.

Seakale is becoming a much more popular subject for forcing than it used to be, and great quantities of roots produced near London are sold all over the country. These roots, however, though well grown, are often half ruined in the lifting, many of them being mere straws not above 5 in. or 6 in. long, with all their extremities broken off; consequently they produce much poorer heads than one would expect, or than they might have done had they not been mutilated. I have seen quantities of these roots forced (all two or three years old), and must say that the produce was sadly inferior to that produced by one year's seedlings. J. S. W.

Early Peas, Potatoes, and Cauliflowers.—I have this day (June 23) gathered my first dish of Peas (William the First) from the open ground, and a most excellent fall crop they are, I have also dug my first dish of Potatoes out-of-doors; the variety is Alma, the finest of all early Kidney Potatoes. Of Cauliflowers I cut the first on May 23; the seed was sown on January 25 and put in heat; they were grown on in small pots and boxes, and planted out.—RICHARD NISBET, *Asbury Park*.

Asparagus wholly Blanched.—As before pointed out, a common error, not only in the case of the public, but of persons who write on the subject, is that French Asparagus is blanched and English green, the fact being that a great quantity of second-class French produce is green, and the larger quantity of the best English Asparagus blanched to nearly the top; but neither the French nor the English really blanch their Asparagus in the sense which the Belgians and the Dutch do. In the best French Asparagus there are pinkish points, which have been allowed to see the light, and in the best English there is a shade of green on the top; but in Belgium and in Holland the whole is blanched in the same way, as thoroughly as we do Seakale. We have just received a specimen of Asparagus from M. Severcyns, grown at Malines, the shoots of which were blanched equally throughout, not a trace of green or pink being visible in the close tops. The shoots sent were about 1 ft. in length, and they had been a long time gathered before they were cooked in London. They were most delicate in flavour, a fact attested by different persons, and they were perfectly edible for the length of 8 in. The flavour was not that bitter kind which sometimes results when the shoots are exposed to the light, but something more delicate, yet retaining the true Asparagus flavour. A very favourable opinion would have to be pronounced upon such if tasted when cut, as all Asparagus should be; therefore, this simply proves to us, even more than any we have before tried, that the common opinion about the value of blanched Asparagus is wholly untenable.

Lilies in Pots for Greenhouse Decoration.—Considering how effective the various kinds of Lilies are when grown in pots, it is remarkable that they are not more extensively grown. A few days ago we saw in the Lily house in Mr. McIntosh's garden at Outlands Park, Weybridge, numerous well-grown specimens which were highly attractive. These comprised *Lilium giganteum*, 9 ft. or 10 ft. high, and bearing several of its large, white, drooping blossoms; *L. parvum*, with from two to three dozen flowers on each flower-stem; the pretty *L. pulchellum* and *L. Hansonii*, as well as the old *L. pyrenaicum*; *L. Martagon* and its white-flowered variety; the many forms of *L. elegans* (Thunbergianum); *L. Washingtonianum*; and the elegant little *L. tenuifolium*, with its brilliant scarlet, turban-shaped flowers, were also well represented.

NOTES OF THE WEEK.

New Varieties of Alpine Gentians.—Mr. H. Gusmus, of Taibach, Austria, has sent us cut blooms of numerous varieties of *Gentiana alpina*. Their colours are remarkably distinct and beautiful, varying from the deepest azure blue to pure white, and in one flower of the latter colour the tips of the corolla are of a rich blue. In all the forms except the white the throat of the corolla is copiously spotted with blue on a greenish ground, and all have greenish marks on the outside. These varieties of *Gentiana* are, we believe, quite unknown in English gardens, but we hope soon to see them adorning our rockeries and flower borders.

Green Asparagus.—There has of late been plenty of green Asparagus from France in the London and other English markets having a flat, mawkish, and most disagreeable flavour, probably from being a long time cut. It is likely that the green Asparagus loses flavour sooner than the thick blanched samples, though we have some reason to believe that certain soils and districts influence the flavour of Asparagus in a marked degree. In any case some samples of Versailles Asparagus sent to the London market were not eatable by many accustomed to the flavour of good Asparagus.

Hedysarum Mackenzii.—This is one of the showiest of the dwarfier kinds of plants belonging to the Pea family. It grows about 1 ft. high, and has slender branches furnished with leaves about 6 in. long, and having from five to seven pairs of small leaflets. The flowers are comparatively large and of a bright rose colour, borne on long slender racemes, which bear flowers successively for a considerable time. Such a pretty plant is well worth growing and is perfectly hardy. It is a native of North America, and was discovered about sixty years ago, but its introduction to our gardens is of a somewhat recent occurrence. It is now in flower at Kew.

Golden-flowered Star of Bethlehem. (*Ornithogalum aureum*).—This is one of the handsomest dwarf-growing bulbous plants which we possess, and yet how seldom does one meet with it in gardens. We, however, saw it the other day in Messrs. Veitch & Son's nursery, where it is grown in pots in a cool house, and bearing long flower-stems terminated by dense racemes of rich orange-coloured blossoms, each about the size of a shilling. It is an old introduction from Asia Minor, we believe, and, though it is generally grown under glass, it is probably as hardy as other subjects from that region.

Dendrobium McCarthiae.—This is one of the most beautiful of all the Dendrobiums, and is now finely in flower at Kew. Its blossoms are larger than those of other kinds, and in colour somewhat similar to that of *D. nobile*, but far richer, and the long pointed lip has a conspicuous zone of pure white intervening between the deep violet-purple colours. The flowers have a natural tendency to droop, and when grown in baskets this peculiarity has a very pleasing effect. It is much to be regretted that this lovely species is reputed to be difficult to manage successfully.

White-flowered Cypripedium acaule.—We learn that a pure white-flowered variety of this beautiful hardy Orchid exists in a noted collection of plants in the United States, and is spoken of as being very handsome. It takes the place amongst hardy Lady's Slippers that is occupied by *C. niveum* amongst those from the Tropics. We hope soon to see this desirable novelty added to our collections, when undoubtedly it will be appreciated.

Double-flowered Wistaria.—This is now in flower for the first time in Mr. Anthony Waterer's nursery at Knap Hill. It is in all respects a decided acquisition, as its blossoms are perfectly double, and last a much longer period in beauty than the original with which it corresponds exactly in colour. We hope soon to see this fine climber in general cultivation.

Scilla (Camassia) Fraseri.—Though of comparatively recent introduction to our collections, this Squill will not compare with the older kinds in point of beauty, and is much inferior to the old *Camassia esculenta*, the flowers being considerably smaller and of a pale purplish shade and produced in short, dense racemes. It is, however, later in flowering than the other Squills and Camassias, which, perhaps, is a desirable quality.

Deep Pots for Lily Culture.—On a recent visit to the rich collection of Lilies in the garden of Mr. G. F. Wilson, who is one of the most successful cultivators of this charming family, we observed that pots of unusual depth are extensively used, and the fine specimens grown in them afford ample proof that deep pots are important in reference to the growth of Lilies. The depth of the pots varies of course with the diameter; thus a pot 8 in. across the top would be about 15 in. deep, and so on in the same proportion. As Lilies are deep-rooting subjects, it is obvious that such pots are more favourable for root extension than the ordinary shallow form.

The Plaited-leaved Viburnum.—This is one of the most attractive shrubs now in flower at the Fulham Nurseries, where it is grown in considerable numbers, and it bears a profusion of its white balls of flowers in a small state, which is a desirable quality. The peculiar plaited appearance of the leaves makes the species from all the others. The large-headed *Viburnum* (*V. macrocephalum*) is also largely grown here, and though not such an abundant bloomer as the preceding, its huge flower-heads, which consist entirely of sterile blossoms, render it very showy and last a long time in beauty.

Eremostachys laciniata.—Fine specimens of this handsome hardy plant are now in flower at Mr. Ware's nursery, Tottenham. The foliage is ornamental, the root leaves being 1 ft. to 1½ ft. long, divided into oblong leaflets, which are deeply jagged. The flower-stems are about 4 ft. high, furnished with numerous leafy bracts that enclose large purplish flowers arranged in whorls. Though an old introduction it is but seldom met with, probably owing to the fact that it is difficult to manage in some localities. It is a capital subject for grouping in masses in proximity with other bold perennials. It is a native of the Levant and Eastern Caucasus.

Pentstemon secundiflorus.—This species, which is one of the finest of the beautiful family of Pentstemon, is now in full beauty in the Kew collection. It is somewhat similar to *P. glaber*, but the leaves are much narrower and longer. The flowers are about 1 in. long, and the colour a bright, clear blue suffused with a pale violet hue, with pencillings of a deeper shade in the throat, and they are arranged in dense, one-sided racemes on stems about 2 ft. high. It is a native of Western North America, and is, we believe, one of the numerous introductions of Mr. Thompson, of Ipswich, to whom our gardens are indebted for many beautiful species of this genus.

Varieties of Wistaria sinensis.—We noticed a few days since, in the nurseries of Messrs. Osborn & Sons, Fulham, a variety of this popular favourite bearing the name of *multijuga*. Its distinctive character is in the unusual length of the racemes, which measure from 1½ ft. to 2 ft. long, and hang from the branches in graceful profusion. The colour, too, of the blossoms is a shade lighter, which adds to its distinctiveness. Another desirable variety is the white-flowered kind, of which there appears to be two forms, one of which seldom develops its flowers perfectly whilst the other is as free flowering as the type. A large specimen of the white-flowered variety grows against a wall, and the effect which it produces, contrasted with the old kind, is very striking.

Delphinium cashmerianum album.—The white-flowered variety of the pretty dwarf Larkspur from Cashmere is now in flower on the rockery at Kew in company with the type with which it contrasts admirably. The flowers are pure white, and are borne in the same profusion as is usual with the original kind. As there are so few, if any, white-flowered kinds amongst the perennial species, the value of this novelty is considerably enhanced, and, doubtless, owing to its producing seeds freely, it will soon be in general cultivation.

The Regent's Park.—We have been lately struck with the beauty of a bit of undulated ground in this park, lying in front of the site of the old Colosseum, the flowering trees and shrubs being remarkable there, and the general effect very pleasing. The contrast between this and similar scenes and the sad geometry of the bedding-out, now being everywhere placed with military precision in the London parks, is very instructive.

Combretum purpureum.—One of the prettiest plants now in flower in the stores at Kew is the above graceful climber. It has rich deep green oblong leaves, from the axils of which are produced large branching racemes of bright red flowers, which are very attractive. Though an old introduction from Madagascar, it is worthy of a place in every stove, and it is moreover very easily grown.

Varieties of Weigela.—We have received from Mr. J. Stevens' garden at Byfleet over two dozen named varieties of these highly ornamental shrubs. They appear to differ chiefly in the habit of growth, which in some is quite erect, in others pendulous, and also in the colour of their blossoms, which varies from the deepest rose, such as may be seen in the variety *Van Houttei*, through all the shades of pink to the snowy white flowers of *W. nivea*, which, without doubt, is among the most beautiful hardy shrubs we have. They are all specially adapted for small gardens, as they are not of rampant growth, and in such seasons as the present, which has been highly conducive to luxuriant growth and profuse flowering, few shrubs present a more showy appearance. There are numerous kinds, too, of the variegated-leaved forms which are desirable for producing a variety of effect amongst other shrubs.

Scent-yielding Plants.—There will be a small but interesting exhibition at the International Agricultural Show, to be held at Kilburn next week (Stand No. 627), of the products of flower farming from a commercial point of view. The acreage under scent-yielding plants is far greater than many suppose it to be. Of Roses, in Bulgaria, there are 5000 acres; Lavender and Peppermints, at Mitcham, 250 acres; Violets, at Nice and Mentone, 300 acres; Orris-root, Italy, 400 acres; Geraniums, Valencia, 250 acres; Lemon Grass, Ceylon, 600 acres; Citronella and Patchouly, Singapore, 270 acres; Jasmine, Acacia, and Tuberoses, Cannes, 400 acres; Orange and Lemon, Sicily and Bergamo, 1500 acres. Other farms exist in Timour and Malaya of which no accurate account can be given.

The Late Mr. Humphreys.—Professor Westwood, of Oxford, pays the following tribute to the memory of H. N. Humphreys in the *Academy*: "On his return from Italy, where his love for art and Nature had been fostered, he was induced by his friend, the late J. C. Loudon, to make a series of drawings of English butterflies and moths, with their caterpillars and the plants on which they feed, the text of which was contributed by the writer of this notice. The plates of these works were zincographed by Humphreys, whose skill in delineation and taste in the arrangement of his figures ensured an extraordinary and extensive sale not only of these entomological plates, but also of the series of quarto volumes on ornamental annuals—bulbous plants, ornamental greenhouse plants, and perennial flowers—planned by Mrs. Loudon; in all of which a number of different species were grouped together in each plate. Subsequently Mr. Humphreys produced a second series of volumes on British butterflies and moths. His task, however, was not confined to plants and insects. He published two volumes of illustrations of Froissart's Chronicles from illuminated MSS. in the London and Paris libraries. His 'Illuminated Books of the Middle Ages,' produced in conjunction with the late Owen Jones, forms one of the most sumptuous volumes published on manuscripts from the eight to the sixteenth century; while his works on the origin of writing, with facsimiles, his books on English coins, in which he ingeniously reproduced each in relief, printed in gold, silver, or copper, and on other coins and medals, and his work on early printed books, in which he introduced a large number of plates, representing full pages from many of the rarest early block and other similar volumes, with his two little works, consisting of the 'Miracles and Parables of our Lord,' with their original and highly elaborate coloured margins, were proofs of his unwearying industry, as they were also of his excellent taste. The two last-mentioned works and his 'History of Writing' were bound in a peculiar plastic embossed material of his own composition, which rendered them highly attractive, but which has not been brought into general use."

ANSWERS TO CORRESPONDENTS.

Laburnum Sports.—I send you three trusses of Laburnum blooms of distinct colours which I cut from one tree. The latter is about 20 ft. high and looks quite handsome, covered, as it is, with the three colours.—F. Dobbs. [Three-coloured blooms on the Laburnum are not uncommon; the flesh-coloured, copper-tinted kind is called *Cytisus Adami*; and the other, C. *purpureus*.]

Clematises.—What is the pretty white Clematis with flowers rather larger than a shilling, now in bloom? Is it *montana* or a variety of it? If not, what is it.—CONSTANCE BAKER. [It is *C. montana*.]

Diseased Leaves.—C. We find no insects or fungi on the leaves sent; they seem to have been injured by frost.

Nertera depressa.—Can you inform me how this plant can be propagated, whether by seeds or otherwise, and if it is hardy out-of-doors?—B. B. [It may be readily propagated by division, which is best effected in spring; the young plants should be kept in a close hand-light or frame until they have become well established. It may also be easily raised from seeds, which should be sown in autumn after being separated from the pulp. It succeeds out-of-doors in summer, but it can scarcely be termed hardy in our climate.—G.]

Mealie.—Will you kindly say in your next issue what kind of plant this is, which forms an important article of food in Natal?—F. H. [Mealie is a common name in Africa for Indian Corn or Maize.—J. B.]

Macropis Wallichii.—Allow me to enquire if any florist has this blue-flowered Himalayan Poppy. It was introduced as a novelty in 1878, and the plant I bought has proved, to my great disappointment, to be only the *M. nepalensis*. I find that both Messrs. Ware & Backhouse have been similarly disappointed, and I begin to think the plant is not in England, or we should have heard of it this summer. *M. nepalensis* has flowered abundantly with us, and two plants of it are bearing thirty or forty capsules filled with ripe seed, so that it is likely to be plentiful. It is quite hardy and is as beautiful in winter, clothed as its leaves are with thickly-set yellow hairs like fur, as when it wears its summer crop of primrose-coloured flowers.—BROCKHURST. [M. Wallichii may be seen in the collection at Kew, and it also exists in various other collections. Some of the leading nurseries no doubt can obtain it for you.]

Names of Plants. *Anon.*—The specimen of *Rhododendron* sent is apparently some unnamed hybrid. *P.*—*Allium Baerianum*. *J. McD.*—3, *Magnolia acuminata*; 4, *Cytisus Emerus*. *A. M. S.*—The fern fronds arrived much withered, and not in a condition for naming them correctly. Send larger specimens with ripe root (seed) at the back of the fronds. *W. C.*—*Tamarix gallica*, *Ceanothus populeus*. *G. W.*—1, *Saxifraga lingulata*; 2, *S. Andrewsii*; 3, *Hesperis matronalis* f. pl.; 4, *Hesperis matronalis*; 5, *Veronica pectinata*. *P. Y.*—*Limonanthus Douglasii* (California). *J. K.*—*Polygala vulgaris*, a native plant abundant throughout Britain. *S. H. S.*—*Rubus autianus*.

Venus' Fly Trap (*Dionaea muscipula*).—I have been told that this will succeed out-of-doors in summer. Can I venture a plant or two out with any chance of success?—H. [The plant in question will thrive admirably out-of-doors during the summer months, provided it is allowed a liberal and constant supply of water. It will also be benefited by allowing live *Sphagnum Moss* to grow on the surface of the pots. W.]

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JUNE 24.

The exhibits at this meeting were unusually few in number; the principal groups were contributed by Messrs. Veitch & Sons; Mr. Fisher, gardener to F. Williams, Esq., Woodlands, Balham, who showed a well-grown collection of *Gloxinias* (to which a silver floral medal was awarded); and Messrs. Barr & Sugden, who showed an interesting collection of cut blooms, Irises, and *Pyrethrums* in rich variety. From the Society's garden at Chiswick came a group of *Begonias*, among which one named *Nellie* May, raised and certificated from Chiswick last year, was remarkable fine, and of a pleasing pink tint. A few examples of hardy *Orchids* were also shown, and an interesting collection of *Pelargoniums*.

First-class Certificates.—These were awarded as follows:—**Xerophyllum asphodeloides** (Wilson).—A rare North American plant, described in THE GARDEN (p. 497).

Davallia filiensis major (Veitch).—An elegant stove Hare's-foot Fern, differing from the type in having larger-sized fronds and broader pinnae.

Begonia Royal Standard (Chambers).—A very fine variety, having good habit and large symmetrical-formed flowers of a brilliant scarlet colour.

Coleus Eva (King).—A kind with foliage grotesquely marbled with various shades of reddish-brown and golden-yellow.

Miscellaneous Plants.—Messrs. Veitch & Sons sent a small group consisting of *Rhododendron Duke of Edinburgh*, a beautiful hybrid with large carmine blossoms, *Eurycler australasica*, a *Pancratium*-like bulbous plant with large and bold heart-shaped leaves and umbels of white flowers. Another showy bulbous plant was *Hemantthus cinnabarinus*, one of the brightest coloured of all the kinds, growing about 1 ft. high. *Ledebouria pendula*, an interesting bulbous plant by no means high, bearing dense pendulous racemes of small greenish flowers with purple-tipped stamens; the leaves are, as in most of its congeners, spotted at the base. *Croton Dracaenae* *Gloxinia* Mrs. Peepoe, and *Vicomte de Condeixa*, but to these we alluded to on previous occasions. These in addition to those certi-

cated, which are enumerated above, comprised this group. Mr. R. Parker sent a flowering branch of *Weigela hortensis nivea*, a pure white-flowered variety, and very desirable seedling. Mr. J. King, gardener, Wray Park, Reigate, contributed *Abutilon Rosy Queen* and *In Memoriam*, also a group of seedling *Coleus* named *Maud*, *Ada*, *Edith*, *Florence*, and *Eva*; the last mentioned received a first-class certificate. Messrs. J. Laing & Co., Forest Hill, showed the fine double-flowered *Begonia* M. Keteleer, of a pleasing pink colour, *Clematis Souvenir de Prince Imperial*, a handsome variety of the *lanuginosa* section, with large flowers, white, with a faint mauve tint running through the centre of each sepal, was contributed by Messrs. Cripps & Son, Tunbridge Wells. Mr. G. F. Wilson, Heatherbank, Weybridge, exhibited a flower-spike of the rare North American *Xerophyllum asphodeloides*, to which a certificate was awarded. Cut blooms of an *Aquilegia* named *Swakeleyi* were also shown; the flowers were similar to *A. cerulea*, but of a much deeper hue. A cultural commendation was awarded to Mr. A. Boxall, gardener, Claybury Hall, Chigwell, for a well-bloomed plant of *Cypripedium barbatum superbum*. *Amaryllis Beauty of Chesterfield*, a brilliant-coloured variety with reflex petals, was shown by Mr. Speed from Chatsworth. A pretty variety of *Azalea amena* named *lateritia* came from Mr. C. Noble, Bagshot, the colour of which was unusual, and of a pleasing soft tint. Seedling *Begonias* were exhibited by Mr. J. Chambers, Westlake Nursery, Spring Grove, Isleworth, and were named *Avalanche*, *floribunda*, and *Royal Standard*, the latter being unusually fine and of a brilliant colour; a certificate was voted to it. B. Victor Emmanuel came from Mr. J. Watson, St. Albans, but it showed no marked advance on the older varieties. *Gloxinia* Surf, a variety with very large and erect flowers, was shown by Mr. W. Fisher, gardener, Woodlands, Nightingale Lane, Clapham; and Mr. Wills showed G. Mrs. Causton, also a fine erect-flowered form with large purple and white blossoms. Mr. H. Cannell, Swanley, contributed cut blooms of a dozen varieties of choice *Pelargoniums*; and Mr. Lye, Market Lavington, pots of *Lobelia Blue Bird*, which no doubt will prove a useful variety.

Fruit.—A cultural commendation was awarded to Mr. Douglas, Loxford Hall, for fruits of *Strawberry Duc de Magenta*, a variety of fair size and handsome form, but the flavour was considered not equal to that of other kinds. Seedling *Melons* (Alpha) were shown by Mr. H. Prinsep, gardener to Colonel Harcourt, Buxted Park, Sussex; and *Melon*, *Netted Victory* also came from Mr. Gilbert, Burghley, as well as two dishes of *Tomatoes*, *Acme* and *Criterion*, to which a cultural commendation was voted. A couple of well-grown fruits of *Sutton's Earl of Beaconsfield Melon* were exhibited by Mr. J. Clark, gardener to Lord Hastings. Messrs. Hardy, of Stour Valley Seed Grounds, Melton Constable, Suffolk, showed examples of their *Eastern King Cos Lettuce*, a large-growing variety, which is said to withstand the most severe weather.

Exhibition of Rhododendrons at Regent's Park.—The brilliant exhibition of these hardy shrubs from the Knap Hill Nurseries is now well worth a visit. It includes a host of novelties associated with the best of the older varieties, and the manner in which they are arranged is very effective. The large numbers of new kinds that have been raised and distributed by Mr. Anthony Waterer is ample proof, if any were wanted, that this class of plants is made a speciality of in these widely-known nurseries. The new varieties not yet distributed, as well as some not yet named, show a marked advance on older kinds, being well varied and rich in colour, combined with large size and finely-formed blossoms, and large compact trusses.

Royal Botanic Society, June 18.—We omitted to mention (p. 509) that floricultural certificates were awarded to the following plants, viz., *Coleus Princess* (Ball); *C. Duchess of Teck* (Ball); *C. Yellow Gem* (Ball); Double-flowered Ivy-leaved *Pelargonium Gazelle* (Ball); *Begonia* Mrs. Arthur Potts (Veitch); *Gloxinia* Mrs. Peepoe (Veitch); *Torenia Bailioni* (Veitch); *Begonia Edith Box* (Laing); *B. Princess of Wales* (Laing); *B. Electric* (Henderson); *Pelargonium Queen of Scots* (Poster); *P. Invincible* (Poster); *P. Amethyst* (Brehaut); *P. Joe* (Matthews); *Tree Carnation Miss James* (Turner); *Lobelia Erinus speciosa Blue Bird* (Lye).

Pelargonium Society.—Although the date on which this Society's show is to be held has been postponed, a few groups were contributed on this occasion, the principal of which came from Mr. C. Turner, of Slough, who showed well-grown examples of the show and fancy varieties. Amongst them a brilliant-coloured variety named *Illuminator* with flowers of large size and fine form, was especially noteworthy. A gold medal was awarded to this fine group. Mr. Foster exhibited a numerous collection of new seedlings, amongst which were many of superior merit. The following were awarded first-class certificates, viz., *Pelargonium Invincible* Emperor William, and Joe.
